Fig 1 Precipitation of guinea pig anti-bovine insulin serum *A* (centre of figure) and some insulin preparations in agar gel, Boots bovine insulin, *BI*, Wellcome pig insulin, *PI*, and mother liquor, *ML*

same manner Berson and Yalow[4] have attributed their failure to find precipitating antibodies in the sera of insulin-treated diabetics to the univalence of insulin Nevertheless, we have found that guinea pigs readily produce precipitating antibodies when immunized with large doses of crystalline insulin preparations, and we present here evidence that these are antibodies to insulin

Bovine insulin, crystallized six times (Boots, Ltd), was dissolved in 0 002 *N* hydrochloric acid and carefully emulsified with Freund's 'Complete Adjuvant' (Difco) to give a final insulin concentration of 1 5 mgm /ml Adult guinea pigs each received 1 0 ml , injected beneath the skin and distributed between three or four sites After 4 weeks a further 1 0 ml was similarly injected and one month later precipitating antibodies to the insulin preparation could be demonstrated in the serum Thirty immunized guinea pigs all produced this type of antibody

Precipitation of the antigen–antibody complex was first detected by the gel diffusion technique of Ouchterlony[5] (Fig 1) Solutions containing 200 μgm / ml of several-times crystallized bovine and pig insulins were placed in the outer wells as was a solution containing 200 μgm per ml of mother liquor solids from an initial crystallization (kindly provided by Dr Lapresle, Paris) This last material contained only 16–18 per cent of the concentration of insulin present in the other wells The guinea pig antiserum in the centre well, although forming a single identical precipitation band with the crystalline insulins, gave no visible reaction with the mother liquor

Specific precipitates of antigen and antibody were measured quantitatively[6], using 1 0 ml amounts of two pools of guinea pig antiserum (*A* and *B*) and varying amounts of two different bovine insulin preparations, crystallized six times (Boots, Ltd , 22 2 units/mgm and Burroughs Wellcome and Co , 25 units/mgm) Mixtures of antiserum and antigen were incubated for 4 hr at 37° C and for a further two days at 4° C The precipitates were washed three times in 2 ml of saline and then dissolved in 2 5 ml of 0 1 *N* sodium hydroxide Total protein was determined from the E_{280}, measured by means of a 'Uvispek' spectrophotometer (Hilger and Watts) with a 1-cm quartz cell A factor of 0 715, estimated for guinea pig gamma globulin in 0 1 *N* sodium hydroxide, was used to convert the E_{280} to mgm protein/ml (Fig 2) At the point of maximum precipitation, pool *B* antiserum gave 1 36 mgm. of specific precipitate with 75 μgm of Boots insulin; pool *A* gave 1 00 mgm with 50 μgm of this insulin preparation but only 0 82 mgm with the Wellcome preparation Assuming that all the antigen was precipitated at the point of maximum precipitation, the ratio of antibody to antigen at this point varies between 15 5 and 19 A single curve using pool *A* and once-crystallized pig insulin (Wellcome) is also shown (Fig 2) The smaller quantity of specific precipitate formed with this heterologous insulin preparation suggests a species specificity which is interesting in view of the finding of Berson and Yalow[7] that bovine insulin is more firmly bound to human 'antibovine-pig insulin' serum than is pig insulin, and also accords with the difference in chemical composition of pig and bovine insulins[8]

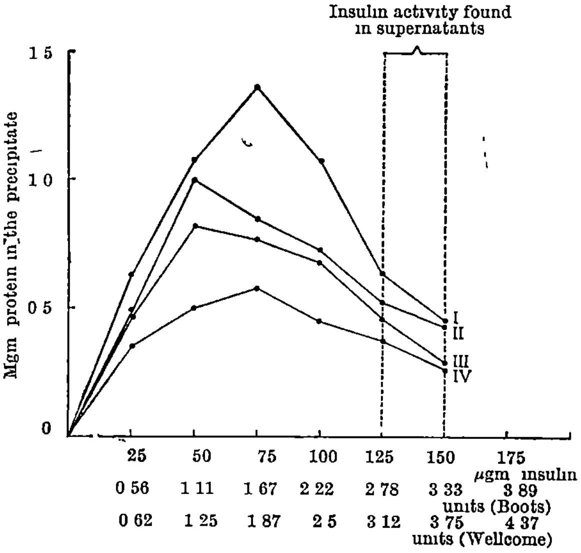

Fig 2. Quantitative precipitation curves using 1 0 ml of antiserum Curve I, pool *B* + bovine insulin, and curve II, pool *A* + bovine insulin (Boots, 22 2 units/mgm), curve III, pool *A* + bovine insulin, and curve IV, pool *A* + pig insulin (Wellcome, 25 units/mgm)

The supernatants obtained after removing the specific precipitates were tested for free antigen and antibody. In relatively large antigen excess, insulin activity was detected by the mouse convulsion test (Fig 2) and both antigen and antibody were detectable in great antigen and antibody excess respectively by precipitation in agar gel Both these methods, however, are relatively insensitive and incapable of detecting amounts smaller than 0·1 unit (4·5 μgm) of insulin in each supernatant

Precipitation, at the point of maximum precipitation, was probably not complete, since, in several experiments with longer incubation periods, somewhat larger specific precipitates were obtained For example, with an incubation period of 7 hr at 37° C , 1 0 ml of pool *B* and 75 μgm of insulin (Boots) gave 1 72 mgm of specific precipitate, corresponding to an antibody–antigen ratio of 22 Attempts were made to check the completeness of precipitation using iodine-131 labelled insulin with a specific activity of less than 1 mc /mgm. (kindly prepared by Dr Samols) Larger amounts of the labelled than of unlabelled antigen were needed to produce maximum precipitation, suggesting that some denaturation of the insulin had occurred Because of this, results were not entirely conclusive; however, 47 per cent of the total radioactivity added was recovered in precipitates which contained only 66 per cent of the total precipitable antigen–antibody protein found when unlabelled insulin was used

An attempt was made, using gel diffusion methods devised by Allison and Humphrey[9], to estimate the size of the antigen molecules which initiate this precipitation The diffusion coefficient was estimated to be 9 6, assuming that the diffusion coefficient of guinea pig antibody is 3 8 The 'molecular sieve' effect of gelatin gels was also used and the antigen diffused through 38 per cent gelatin Both methods indicate that the molecular weight is less than 24,000

These preliminary results suggest that the precipitating guinea pig antibody is indeed antibody to insulin and not to an impurity in the preparations If this is so, it can be concluded from the results of the experiments designed to estimate molecular size of the antigen, that the insulin antigen is mostly in the aggregated form.

We are grateful to Dr E Samols, Royal Free Hospital, London, for preparing the labelled insulin This work is supported by grants from the British Diabetic Association and the Joint Research Committee of King's College Hospital and Medical School

ANTIBIOTIC PROPERTIES OF MYCELIUM AND METABOLITES OF *MYROTHECIUM RORIDUM* TODE

By ANDRZEJ NESPIAK, MARIAN KOCÓR and ANTONI SIEWIŃSKI

Departments of Phytopathology and General Chemistry, College of Agriculture, Wroclaw

THE fungus *Myrothecium roridum*, belonging to the Fungi Imperfecti, group Moniliales[1], is known as a parasite of leaves of *Gardenia*, tomatoes, violets, kidney beans and some other plants[2,3] It has been also found in soil[4] and in the dead plant tissues A detailed morphological analysis of species of *Myrothecium roridum* and related *Myrothecium verrucaria* and *Myrothecium inundatum* was undertaken by White and Downing[5] on the basis of observations of several strains They confirmed the great morphological similarity between *Myrothecium roridum* and *Myrothecium verrucaria*, and also found that these two species differed only in their manner of decomposition of cellulose, and their occurrence They also demonstrated the complete identity of *Myrothecium roridum* with a species known as *Metarrhizium glutinosum* Pope, which produced, according to Brian and McGowan[6], a new metabolite, glutinosine

The scarcity of data on metabolite production by *Myrothecium roridum*[7,8] directed our attention to this problem, and now we present some observations on the activity of the mycelium and the metabolites of *Myrothecium roridum* towards some fungi pathogenic for cultivated plants

The strain of *Myrothecium roridum* isolated by one of us[9], and used for further experiments, has been characterized by formation on glucose-potato-agar of a dense, white mycelium with concentric black sporodochia The smoky, light olive-green conidia (8–10μ long, 2–4μ thick) form black, slime masses, consisting of cylindrical or spindle-shaped cells containing oil drops The fungus grows and sporulates very easily both on malt-agar and on malt liquid (20 gm malto-extract produced by Spółdzielnia Pracy 'Warta' Śrem (Poland) in one litre distilled water), in the latter case the concentration of sporodochia not being easily visible

For the biological tests of fungicidal activity of *Myrothecium roridum* the following species of fungi were used *Penicillium notatum*, *Aspergillus fumigatus*, *Aspergillus niger*, *Fusarium equiseti*, *Fusarium anguioides*, *Fusarium* sp, *Mucor* sp, *Alternaria*

Analysis of the metabolic solution of *Myrothecium roridum* in the usual way, that is, extraction with chloroform, chromatography on activated alumina and crystallization, yielded one major and two minor crystalline metabolites. The major metabolite, which we called myrothecin, has a molecular weight of 334, and on this basis and on its elemental analysis it was assigned the formula $C_{18}H_{22}O_6$. The substance does not melt at temperatures up to 350° C and has $[\alpha]^{20}_D = +174°$ (in chloroform).

The second metabolite has a melting point of 204–205°, the third one 115–120°. It must be stated that these compounds could be isolated only when *Myrothecium roridum* was grown on malt liquid, otherwise an entirely different production of metabolites occurred.

The biological tests were carried out in the following manner:

(1) The mould *Myrothecium roridum* was grown in Petri dishes on potato- or malt-agar, and simultaneously, or after 4 days, the species investigated were inoculated at distances of 4 cm. The zones of inhibition were measured in millimetres. (2) The crude filtrates of the metabolic solution of 4-week-old cultures of *Myrothecium roridum* were investigated for their fungicidal activity in the following way: filtrates were used for the preparation of the 5 following media, on which the test fungi were grown:

(*a*) 1 litre filtrate + 20 gm. agar; (*b*) 0.5 litre filtrate + 0.5 litre malt liquid + 20 gm. agar; (*c*) 1 litre filtrate passed through active charcoal + 20 gm. agar; (*d*) the same filtrate + 0.5 litre malt liquid + 20 gm. agar; (*e*) dried mycelium from 4-week-old cultures of *Myrothecium roridum* suspended in 1 litre distilled water + 20 gm. agar, and (*f*) control medium prepared from malt liquid + 20 gm. agar.

(3) The chloroform extracts of the metabolic solution of *Myrothecium roridum* were investigated by means of the paper-disk plate method. Approximately 10 mgm. dried chloroform extract (or crystals) were dissolved in chloroform, and 20 filter paper disks were saturated with this solution. After drying, each disk was moistened with water and put on a malt-agar medium, into which the suspension of spores of the test fungus was inoculated. The zones of inhibition were measured in millimetres.

The results are presented in Table 1; they show that:

(1) The growing mycelium of *Myrothecium roridum* inhibits strongly the growth of the majority of test fungi except the quickly developing species. (2) The metabolic solution of *Myrothecium roridum* also has a strong inhibiting effect, when not treated with charcoal, which adsorbs the fungicidal metabolites. The suspension of dried mycelium is not very active. (3) The major metabolite (myrothecin) is not very active, whereas the first minor metabolite (melting point 205° C.) and the non-crystalline mother liquors are highly active. (4) *Myrothecium roridum* does not produce glutinosine, but a number of crystalline compounds (at least three) and possesses high fungicidal activity.

EFFECT OF WHOLE-BODY IRRADIATION AND CORTISONE ON THE DEVELOPMENT OF *OSTERTAGIA* SPP. IN SHEEP

By J. D. DUNSMORE

Department of Veterinary Pathology and Bacteriology, University of Sydney

Effect of Whole-Body Irradiation on Antibody Response of Sheep

In the course of experimental work on the life-cycle of sheep helminths it became necessary to utilize experimental methods of suppressing the sheep's antibody response. One method of accomplishing this is by whole-body irradiation; in view of the lack of available data on response of the animal to whole-body irradiation the following is presented to indicate the results that I have obtained.

Information available (*Handbook of Biological Data*, W. B. Saunders Co.) indicated that the LD_{50} (30 day) for goats, the species nearest sheep for which data were available, was 350 rads. It also appeared that the dose necessary to suppress antibody response is about 80 per cent of the LD_{50}. Hence the initial test dose was approximately 300 rads. The irradiation source used was 310 c. cobalt-60, to which the sheep was exposed at a distance of 160 cm. Half the exposure was delivered to each side of the sheep. Total exposure was 4.5 hr. to deliver 300 rads. The test antigen used was a formalin-killed suspension of *Salmonella typhimurium* injected 36 hr. and 5 days following irradiation. This had been shown to induce marked agglutinin production in normal sheep. In a sheep exposed to 300 rads only a slight reduction in antibody response was noted although the leucocyte count dropped to a minimum (48 hr. post-irradiation) of 960 per mm.^{3} with only 2 per cent lymphocytes in the differential count.

Following this initial test two sheep were each exposed to 440 rads (6 hr. exposure, 160 cm. from 310 c. cobalt-60) and subjected to similar antigenic stimulus. No antibody was detected by orthodox agglutination techniques up to 19 days following irradiation in the first sheep. The second sheep died suddenly 14 days after irradiation without having developed any detectable antibody to the *Salmonella* antigen. At autopsy there was evidence of septicæmia and a Gram-negative bacillus was cultured from heart blood, but not identified.

These results indicated that 440 rads, applied equally to both sides of the sheep, suppressed antibody production as assessed by the response to a formalin-killed *Salmonella typhimurium* antigen

Following these preliminary experiments, four sheep have been irradiated at the above dose In all cases the hæmatological picture indicated a very severe depletion of body lymphocytes with total white cells dropping in all cases to less than 20 per cent of the pre-irradiation figure, the minimum being reached 48 or 72 hr following irradiation The lymphocytes were the cells most affected initially, dropping to less than 2 per cent in all cases within 72 hr and then rising again during the next two weeks The granulocytes reached a minimum 7–10 days after irradiation so that at this stage the total count was sub-normal, of which about 80–90 per cent were lymphocytes From the experimental results obtained in this work on the role of immunity to developing helminths it did appear that the host immunological response had been depressed The nature of the experiment prevented any attempt to confirm this serologically

In all the sheep a febrile reaction was noted which became severe (temperature exceeding 106°F) in two animals The experiment did not allow antibiotic therapy so that these sheep were killed and autopsied 13 and 14 days after irradiation The remaining two sheep survived the full 15-day experimental period with little evidence of harm The two sheep severely affected both showed septicæmia with severe gastro-enteritis, but again the Gram-negative bacillus isolated did not fit a readily identifiable bacterial group Splenic and lymphoid tissue in all sheep was markedly atrophied and bone marrow smears showed severe agranulocytosis The hæmatological picture had showed that the early lymphocytopenia was later replaced by a relative lymphocytosis as the total granulocyte count became depressed (7–10 days following irradiation) In two sheep that survived irradiation and experimentation the hæmatological picture took 12 weeks to return to normal

It appears that 440 rads whole-body irradiation will largely suppress the antibody response of sheep, but the sheep is likely to succumb to bacterial infection unless protected by antibiotics

Effect of Cortisone and Whole-Body Irradiation on Development of *Ostertagia* spp. in Sheep

It has been shown previously[1] that the development of a large percentage of the parasites recovered from a sheep following a single large dose of *Ostertagia* spp larvæ is arrested, and that 14 days following infestation the larvæ are still only in the early 4th stage of development In an attempt to determine whether this arrested development is due to an immunological response by the host, an experiment was carried out with the object of destroying or reducing the host immunological response by the use of cortisone and by high-level, whole-body irradiation

In the experiment, 4 groups were used each of 3 sheep which had been raised free of strongyle parasites and were approximately 6 months old One animal in each group received larvæ only and acted as an untreated control, one was irradiated and one was treated with cortisone Irradiation at the rate of 440 rads per animal delivered in two equal parts to each side has been found to be effective in largely eliminating agglutinin response to an injected formalized *Salmonella typhimurium* antigen (see previous article) This dose was given 24 hr prior to larval administration Hydrocortisone alcohol was injected intramuscularly at a dose of 4 mgm /kgm body-weight daily commencing 5 days prior to administration of larvæ 100,000 *Ostertagia* spp larvæ were injected directly into the rumen, each member of each group receiving larvæ from the same batch

The sheep were killed 14 days after administration of larvæ and the parasites were collected after thorough washing of the abomasum and peptic digestion of the abomasal wall The parasites were counted and classified as 'normal' or 'arrested' forms (Table 1) Those recorded as 'arrested' were still in the early 4th stage of development At least in the untreated control group the unarrested larvæ should properly be classified as 'retarded', these larvæ not having attained the size that can normally by expected of *Ostertagia* spp if given at a low level of infestation Thus a population of *Ostertagia* spp might include some 'arrested' forms (that is, development temporarily ceased in the very early 4th stage), some 'retarded' (the final morphological stages of development have been reached but the size attained is sub-normal) and normal adults of the genus

Table 1

	Group No	1	2	3	4	Means
Cortisone treated	Sheep No	57	54	64	72	
	Total recovered	53,600	31,400	29,150	15 540	32,420
	Number 'arrested'	6,930	1,200	200	2,740	2,770
	Percentage 'arrested'	12 9	3 8	0 7	17 6	8 5
Irradiated	Sheep No	61	63	55	59	
	Total recovered	43,670	27,520	13,200	43,200	31,900
	Number 'arrested'	13,540	2,860	2,600	4,860	5,960
	Percentage 'arrested'	31 0	10 4	19 7	11 3	18 7
Control	Sheep No	68	53	56	62	
	Total recovered	50 130	26,000	20,450	24,000	30,140
	Number 'arrested'	16,130	7,340	14,600	14,060	13,030
	Percentage 'arrested'	32 2	28 2	71 4	58 5	43 2

Larval arrest was very much less in cortisone-treated (8 5 per cent) and in the irradiated sheep (18 7 per cent) than in the controls

Although both cortisone and irradiation cause a variety of effects on the physiological status of sheep, an alteration common to both treatments is a reduction in the capacity of the animal to respond immunologically to a parasitic invader It is suggested that reduced immunological responsiveness by the treated sheep may have been the factor which permitted the greater percentage of unarrested development of *Ostertagia* spp as compared with that in the control animals It is postulated that in normal sheep which have had no contact with *Ostertagia* spp or related parasites, a rapid, probably local, immunity reaction leads to the formation and release of factors causing a specific arresting of development of many of the parasites Although the larvæ were introduced into the rumen by a single injection it is probable that entry to the abomasum will extend over a period of possibly up to 48 hr It may be that the first larvæ which reach the abomasum cause a local immunity reaction leading to the arrested development of later arrivals

HEART DIPOLE REGIONS AND THE MEASUREMENT OF DIPOLE MOMENT

By Dr M. R. BARBER
Naval Research Laboratory
AND
Dr E J FISCHMANN
Cardiology Department, Green Lane Hospital, Auckland, New Zealand

Measurement of Specific Dipole Regions within the Heart

MOST electrocardiograph leads used to-day do not differentiate between dipoles from various parts of the heart, but instead give a mixture of all dipoles in unknown proportions Fischmann and Barber[1] have shown that this applies to so-called 'unipolar' chest leads no less than to standard lead I If it is assumed that there are N dipole regions in the heart, each of which can be represented by a single dipole, then it is possible to make an electrolytic tank analogue of homogeneous conductivity enclosing a heart model of somewhat higher conductivity The N dipoles can be placed in the appropriate positions on the heart model If N electrodes are now distributed over the body surface it is possible to measure N sets of N potentials as each of the dipoles $a,b,c,$, etc , is excited to unit strength in turn

Alternatively, if all the N dipoles are excited to different strengths simultaneously and N voltages are measured in the same positions on the body surface, then it is possible to calculate the strengths of each of the N individual dipoles by solving N linear simultaneous equations The coefficients in the equations are obtained from the $N \times N$ set of potentials described above The dipole strengths will appear in the form

$$\mu_a = a_1 V_1 + a_2 V_2 + a_3 V_3 + \qquad + a_n V_n$$

where V_1, V_2, V_3, etc , are the body surface potentials

In practice it is convenient to use the formulæ to design resistor networks which perform automatically the additions of element voltages to give μ_a, μ_b, μ_c, etc By switching to a particular network it is then possible to display the effects of a chosen dipole on a two-terminal electrocardiograph The effects of all other dipoles will be eliminated

Work applying this method to the human torso is in progress and will be published Accuracy will depend obviously on how closely the analogue represents the electrical properties of the human body under investigation

Clinical Method for the Quantitative Measurement of the Heart's Total Dipole Moment

THE electrical phenomena associated with the human heart may be attributed to a group of dipoles arbitrarily orientated within a homogeneous medium and producing a set of potentials V_1, V_2, V_3, V_n at n points on the body surface An application of Green's reciprocity theorem[2,3] makes it possible to measure the collective dipole strength[4] by applying currents at each of the n points and measuring the fields at the dipole positions

For example, if the dipoles of strengths μ_1, μ_2, μ_3, , μ_n establish potentials V_1, V_2, V_3, . V_n on the surface, then field strengths E_1, E_2, E_3, E_n, will exist at the dipole positions when equal currents of magnitude I are applied to each of the n points, where

$$I(V_1 + V_2 + V_3 + \ldots V_n) = \mu_1 E_1 + \mu_2 E_2 + \mu_3 E_3 + \ldots \mu_n E_n$$

If the field in the region of the dipoles is uniform and Z directed (E_Z) then the resultant Z component of all the dipoles may be written

$$\sum_1^n \mu_z = \frac{I \Sigma V}{E_Z} \tag{1}$$

Since the dipoles are likely to be orientated randomly it is desirable to establish three mutually perpendicular fields and thereby measure the three resultant dipole components The main problem is to measure the electric field since the interior of the body is generally inaccessible This can be resolved, however, by arranging that the flow of current from the electrode is uniform and calculable throughout the body

If a homogeneous three-dimensional body is box-shaped, it is obviously possible to establish a uniform field within it by applying a uniform current density over one pair of opposite faces If the conducting medium is replaced by a rectangular three-dimensional fine-mesh resistor network then a similar result will be obtained if equal currents are applied to all leads emerging from one pair of opposite faces If an irregular-shaped body is now removed from within the box then the uniform field within the body can be preserved if the original currents are maintained at the newly exposed boundaries, that is, equal currents in one direction but zero on the other two

The situation described can be approximated on the human torso if electrodes are uniformly spaced on a flat platform placed on the chest Similar electrode clusters can be used for sides and back although for the back electrode it is usually sufficient to use electrodes mounted on a flexible sheet[5] The electrodes protruding from the platforms can be sprung so that they press firmly on to the body contours

The approximately uniform field within the body between a pair of such electrodes is simply

$$E_z = \rho\, i$$

where ρ is the conductivity of the body, assumed uniform, and i is the average current per unit area projected on to the platform

The expression may also be written as

$$E_z = \frac{\rho I}{A_{xy}} \tag{2}$$

where I is the current applied to each of the elements of the cluster and A_{xy} is the small rectangular area enclosing one and extending half-way in all directions to the adjacent element Combining equations (1) and (2) we obtain

$$\sum_{1}^{n} \mu_z = \frac{\Sigma V}{\rho} \quad A_{xy}$$

as the resultant z component of the dipoles distributed throughout the chest region

The field produced by the electrode will obviously not be exactly uniform if the electrode elements are spaced at finite intervals and cover a limited area However, with a frontal cluster having 30 elements and covering an area 10 in × 14 in it has been found from model experiments that the fields in the heart region are calculable to within 10 per cent assuming the body to be perfectly homogeneous

A paper describing, in detail, an orthogonal electrocardiograph lead system, which employs platform-mounted multiple electrodes, will be published[6] Using a new non-paste electrode material developed by Fischmann *et al* [7], consisting of balsa-wood impregnated under vacuum with lithium chloride, leads *X*, *Y* and *Z* take as much time to record as three standard electrocardiograph leads

CATION-EXCHANGE CAPACITIES OF TISSUES OF HIGHER AND LOWER PLANTS AND THEIR RELATED URONIC ACID CONTENTS

By A H. KNIGHT, W. M CROOKE and R H. E INKSON
Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen

SINCE the early work of Devaux[1], which showed that plant tissues possess cation-exchange properties, many workers have measured the cation-exchange capacity (C E C) of the roots of higher plants[2] Their findings are that dicotyledons have roughly twice the C E C of monocotyledons and that the C E C 's of the common agricultural crops lie in the range 10–60 m equiv /100 gm dry matter Much of the recent interest in this topic stems from the possible effect of C E C on the mineral composition of the plant In particular, if Donnan distribution principles hold, the higher the root C E C the higher would be the sorption of divalent over monovalent cations (valence effect) The characteristic differences in calcium and potassium contents of monocotyledons and dicotyledons—the former low in calcium and high in potassium, the latter high in calcium and low in potassium—are in keeping with the measured differences in their root C E C

The majority of measurements of C E C of roots have been made on agriculturally important[3] or ornamental plants[4] grown in nutrient culture (nutrient solution, sand or gravel culture) for ease of recovery of roots These solutions are generally too concentrated to allow the valence effect to be reflected in the plant composition Under these conditions it has been found that the C E C of a particular species can be altered to some extent by change in nitrogen[5], phosphorus[6] or heavy metal supply[7]

The indiffusible anions in the plant roots to which the C E C could be attributed were demonstrated to be pectic substances by Mattson[8], using staining tests Decarboxylation methods of estimating uronic acids, supported by chromatographic identification of extracted uronic acids, were used by Keller and Deuel[9] for plant roots and by Knight *et al* [10] for disks of plant storage tissue It was shown that a large part of the C E C could be accounted for as pectic substances

Brief reports on the C E C of other organs (leaves and stems) of higher plants[11], and on the C E C – uronic acid relationship[12] have been published recently. The exchange properties of lower plants have been noted (marine algae[13], yeasts[14], bacteria[15], fungi[16], mosses[17]) but not in relation to uronic acid content

An adequate test has never been published of the influence of soil factors on the C E C of plants Earlier work had shown that it was possible to recover plant roots from soil[18], and it was therefore decided to examine the effect of soil-type on the C E C and uronic acid content of natural vegetation Such plants, since they grow under very poor nutritional conditions, also seemed more likely to offer experimental material which might show the relationship between root C E C and mineral composition

Plants were therefore collected from sites varying widely in drainage, *p*H and calcium supply The sites are described more fully in Table 1 In all, about 80 species were collected, but only 12 (5 monocotyledons and 7 dicotyledons) were common to all 4 soil types Tops were separated into leaves and stems (where appropriate), dried overnight at 80° C and major element cations determined in the ash After washing, root systems were divided into tap roots, rhizomes and fine roots (where appropriate), dried overnight at 80° C and milled to pass a 0 7 mm sieve The C E C was measured using an acid-washing technique followed by titration to *p*H 7 using 0 01 *N* potassium hydroxide[7] Uronic acids were estimated by a micro-decarboxylation method[19] and the results are expressed in m equiv /100 gm assuming all carbon dioxide was derived from carboxyl groups

Fig 1 shows the relationship found between the uronic acid content and the C E C of the roots The diagonal line represents the theoretical 1 1 rela-

Table 1 DESCRIPTION OF SITES

Soil type	Site	*p*H	% Loss on ignition	Exchangeable cations m equiv /100 gm oven-dry soil Ca	K
Sand	Newburgh, Aberdeenshire	4 8–6 8	—*	—*	—*
Peat	Gardrum Moss, near Falkirk	4 0	72	12 9	0 75
Acid soil	Craigiebuckler, Aberdeenshire	6 5	6	7 5	0 39
Calc soil	Limehillock, Banffshire	8 0	12	55 0†	0 38

Additional sites sand, Maryculter and Glendye, Aberdeenshire, peat, Mossmaud and Lyne of Skene, Aberdeenshire , acid soil, Bridge of Alford, Aberdeenshire , calcareous soil, Blackhillock, Banffshire
* Not determined , † This soil yielded 15 3 per cent CO_2, equivalent to 34 8 per cent $CaCO_3$

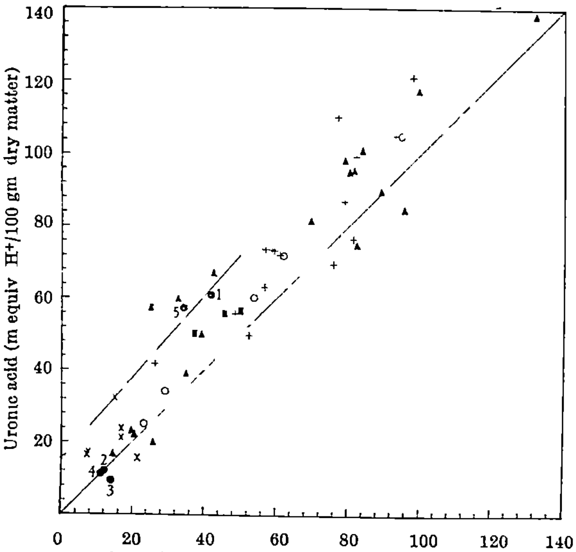

Fig 1 Relationship between cation-exchange capacity (C E C) and uronic acid content (in m equiv /100 gm) for the roots of higher plants Lower plants are indicated thus ferns (4, ■), mosses (15, +), marine algae (18, ▲), and fungi (6, ×) Numbered points are 1, liverwort, 2, lichen, 3, bacteria, 4, yeast, 5 *Equisetum* Open circles are Keller and Deuel's results

tionship The short solid line is derived by the method of least squares from the results of 62 samples, embracing the 12 angiosperm species ranging in C E C from 6 to 50 m equiv /100 gm dry roots, which were common to all 4 soil types The total of 62 samples is explained by the fact that there were several sampling sites for each type of soil Table 2 gives the mean values for these 12 plants Statistical examination shows that there are no significant differences between the individual regression lines calculated from the data for each of the 4 soil types

The slope and intercept of the line in Fig 1 show that C E C is, in general, accounted for by uronic acid content, but there is included in the ordinate a proportion of esterified carboxyl groups which yield carbon dioxide, but do not take part in cation exchange The effect of interfering substances on the decarboxylation results has been discussed[10,19]

It was found that the C E C–uronic acid relation also held for different parts of the same plant For example, for *Heracleum* sp the values (in m equiv /100 gm dry matter) for C E C and uronic acid are, respectively roots, 25 8, 49 5; tap root, 26 0, 52 0, stem, 26 7, 52 5, leaves, 26 3, 70 7 It would appear that leaves contain a higher proportion of substances which yield carbon dioxide but do not take part in cation exchange

To extend the data to include gymnosperms, the roots of 23 species of one-year-old conifer seedlings growing on the acid soil were also examined and the C E C. (17 9–30 8, mean 25 3) and uronic acid values were found to fall on the same line as the Angiosperms, but for clarity these results are not plotted For comparison with the results of other workers, values obtained by Keller and Deuel[9], using somewhat different techniques of plant culture and analysis, have been plotted. These are shown by open circles and are for the roots of 4 crop plants and one ornamental plant, larkspur[20], which gives the highest value

Table 2 AVERAGE VALUES (IN M EQUIV /100 GM) OF C E C AND URONIC ACID (U A) CONTENT OF PLANT ROOTS GROWN IN DIFFERENT SOIL TYPES

Growth medium	Sand		Peat		Acid soil		Calcareous soil	
	C E C	U A	C E C	U A	C E C	U A	C E C	U A
Monocots (5 spp)	13 2	28 1	12 3	27 2	12 6	24 8	13 3	28 5
Dicots (7 spp)	25 0	45 7	32 8	49 1	27 2	48 3	30 8	48 0

Having established the line for the higher plants, it was decided to perform tests on a few species from the other major groups in the plant kingdom These results have been plotted on Fig 1 and are made up of. ferns (4, ■), mosses (15, +), marine algae (18, ▲), fungi (6, ×) Single samples of liverwort, lichen, soil bacteria, yeast, and *Equisetum* sp are indicated by solid circles numbered 1–5, respectively These determinations were carried out on whole plants except in the case of ferns and *Equisetum* where roots were used All samples were oven-dried, then milled as for the higher plant roots

It would appear that the C E C and its related uronic acid value is a characteristic of the roots of angiosperms and is independent of a wide range of growth conditions The C E C–uronic acid relationship is also shown by other organs of the plant For lower plants there also seems to be a general relationship between C E C and the decarboxylation value of the dry matter Different substances may be involved in the production of carbon dioxide for the different plant groups, and 'uronic acid' is used only as a convenient overall expression It is reasonable to suppose that the uronic acid in the roots of angiosperms is mainly polymerized galacturonic acid (in other words, pectic substances) but little is known of the occurrence of these compounds in the lower plants In brown algae, the uronic acid is probably alginic (that is, a polymer of mannuronic acid) From the results obtained here, it is noteworthy that among the marine algae the C E C values fell into two clear groups, those of the brown algae being 70 and above and those of the red and green algae 56 m equiv /100 gm dry matter and below The presence of ethereal sulphate in seaweeds which would contribute to C E C but not to the decarboxylation value would obviously affect the relationship

We thank R, Boggie, E Birse, Miss M E K Henderson and Dr H G M Hardie for their assistance, J E Shackleton, of Ben Reid's Nursery, Aberdeen, for supplying the conifer seedlings, and E Booth, of the Institute of Seaweed Research, Inveresk, for samples of marine algae

IMPORTANCE OF OSMOTIC POTENTIAL AS A COMPONENT OF THE TOTAL POTENTIAL OF THE SOIL WATER ON THE MOVEMENT OF NEMATODES

By C D. BLAKE
Rothamsted Experimental Station, Harpenden, Hertfordshire

THE force with which water is held in a soil can be specified in terms of a total water potential (ψ), identified as the free energy of the soil water, and is conveniently expressed as $pF = \log_{10}(-\psi)$ This total potential is the sum of a matric potential or suction (h), caused by hydrostatic pressure deficiencies existing in the soil water, and an osmotic potential (π), caused by dissolved salts

Horizontal migration of the nematodes, *Heterodera schachtii* Schmidt and *Ditylenchus dipsaci* (Kuhn) Filipjev, through sands wetted with distilled water is affected by the matric potential applied to the sands[1] In these conditions the total potential equals the matric potential, that is, the suction applied, and there is no information on the effects of osmotic potential I therefore compared the movement of *D dipsaci* larvæ in a sand of particle size 250–500μ with and without an osmotic potential In one lot of experiments the sand was saturated with distilled water and suctions of 0–100 cm water applied The larvæ that moved horizontally more than 3 cm in 5 hr through the sand column were counted and expressed as a percentage of the number of larvæ introduced In the other experiment the sand was saturated with a 0 1 M solution of urea and suctions of 0–100 cm water applied

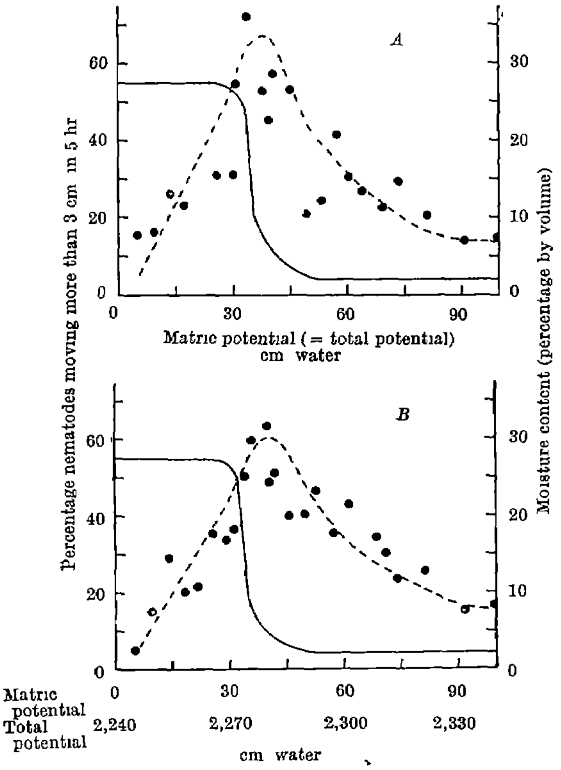

Fig 1 Horizontal migration of *D dipsaci* through sand at different total potentials Each point is the mean of two replicates In *A* the sand is wetted by distilled water (osmotic potential = 0) and in *B* by 0 1 M urea solution (osmotic potential = 2,240 cm water) The moisture characteristic of the sand is shown as a solid curve

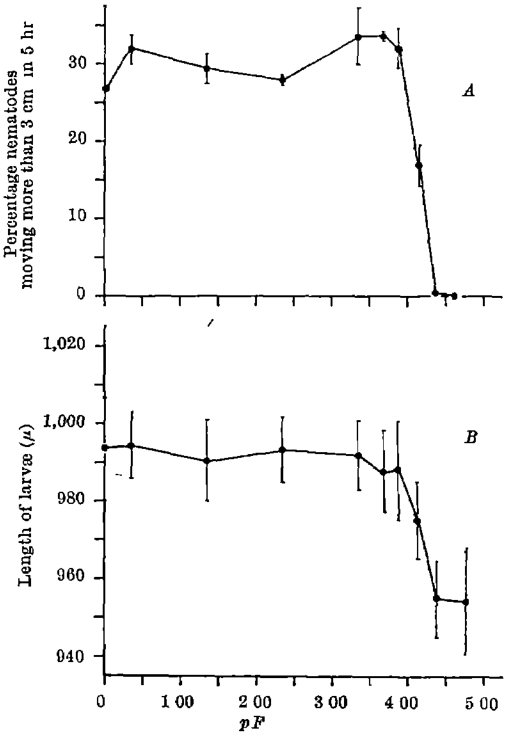

Fig 2 *A*, Horizontal migration of *D dipsaci* through sand wetted with urea solutions of different concentrations Each point is the mean of five replicates and the standard error of each mean is shown by a solid line through the point *B*, Length of *D dipsaci* larvæ measured after immersion for 36 hr in urea solutions of different concentrations Each point is the mean of fifty measurements and the standard error of each mean is shown by a solid line through the point

Fig 1 shows that the larvæ moved similarly whether the sand was wetted with distilled water or urea solution, movement in both was related to the moisture characteristic and was fastest as the pores of the sand began to drain, showing that movement depends only on the moisture content and is independent of the osmotic potential The extrusion of the mass of larvæ of *Anguina agrostis* (Steinbuch) Filipjev from flower galls was also sensitive to suction but unaffected by changes in osmotic potential within the range of 0–300 cm water[2]

The mobility of *D dipsaci* larvæ was also measured in 250–500μ sand saturated with solutions of 0·0001 M–2 M urea and drained by a suction of 32 cm water The percentage of larvæ that moved more than 3 cm in 5 hr was not influenced by the osmotic potential of the sand solution until the concentration exceeded

Table 1 EXPECTED CHANGES IN THE TOTAL POTENTIAL OF A TYPICAL SOIL, MOISTURE CONTENT 20 PER CENT W/W, AFTER ADDITION OF DEXTROSE AT SIX LEVELS/ACRE TO A DEPTH OF 8 IN

Rate of application of dextrose to soil		Matric potential of soil (cm water) (h)	Osmotic potential of soil before dextrose added (cm water) (π_1)	Total potential of soil before dextrose added (cm water) ($\psi_1 = h + \pi_1$)	Molar concentration of dextrose in soil water	Osmotic potential of dissolved dextrose (cm water) (π_2)	Total potential after dextrose added ($\psi_2 = \psi_1 + \pi_2$)	
Per cent w/w	Tons/acre						cm water	$pF = \log_{10}(-\psi_2)$
0 1 (1,000 p p m)	1	75	400	475	0 028	627 2	1102 2	3 04
1	10	75	400	475	0 28	6272	6747	3 83
2	20	75	400	475	0 56	12544	13019	4 11
3	30	75	400	475	0 84	18816	19291	4 29
4	40	75	400	475	1 12	25088	25563	4 41
5	50	75	400	475	1 40	31360	31835	4 50

0 3 *M* (*pF* = 3 87), when it decreased and movement ceased at 1 *M* (*pF* = 4 35) (Fig 2*A*)

The length of the fourth-stage larvæ of *D dipsaci* suspended in urea solutions decreased as the osmotic potential of the solutions increased

Shrinkage was greatest in the range of 0 001–1 *M* concentration and the larvæ reached their minimum lengths at *pF* approximately 4 1 (Fig 2*B*) Larvæ in the 1 *M* and 2 *M* urea solutions were killed, but those transferred to distilled water after 36 hr in solutions of 0 001 *M*–0 3 *M* urea regained their activity and former length

Dextrose and three salt solutions ranging from 0 2 to 1 *M* depressed hatching of eggs of *H rostochiensis* Woll and *Meloidogyne arenaria* (Treub) Chitwood, but in all experiments hatching was resumed when the eggs were transferred to water[3] Emergence of larvæ from cysts of *H schachtii* similarly decreased rapidly as the solute concentration exceeded 0 01 *M* regardless of the solute used[4] The speed of movement of *D dipsaci* declined when the solute concentration exceeded 0 1 *M* and the movement of *D dipsaci* and the emergence of *H schachtii* both ceased at about 1 *M* (*pF* = 4 35) This potential approximates to the permanent wilting point of plants

Matric potential affects nematode migration by varying the thickness of the water films surrounding the soil particles[5] Figs 1 and 2 show that the rate of movement of *D dipsaci* in sand depends only on the matric potential and is independent of the osmotic potential until the solute concentration is such as to cause incipient plasmolysis of the nematode In most fertile soils the salt concentration of the soil water does not exceed 0 05 *M* (*pF* = 3 05) and so nematode movement through a soil is normally governed not by the total potential but by the matric potential of the soil system

Sucrose or dextrose applied to soil at the rate of 1–5 per cent by weight of soil has been claimed to be nematicidal and proposed as a method for controlling plant parasitic nematodes in field-crops[6] Assuming the dextrose was thoroughly mixed in a soil of moisture content 20 per cent w/w to a depth of 8 in , that the osmotic potential of the soil water before treatment was equivalent to 400 cm water and that the matric potential of the soil was 75 cm water, it is of interest to calculate the changes in *pF* of the soil after adding dextrose at the rates of 1–5 per cent by weight suggested (Table 1)

The growth of most plants becomes slower as the total potential exceeds *pF* = 3 30 and stops at *pF* = 4 00 (ref 7) With 0 1 per cent dextrose, the resultant *pF* of 3 83 may retard plant growth, but from Fig 1 such a total potential would probably not slow nematode movement The *pF* at which nematodes are killed by ex-osmosis approximates to the *pF* at which plants permanently wilt Unless sugar were applied only during a period of bare fallow, it is difficult to see practical uses for the treatment if it were economic Even during bare fallow, such large quantities of pure carbohydrate could be expected to render nitrogen temporarily unavailable and induce profound changes in the soil microbial community

This work was done while I held the Sir Benjamin Fuller Trust scholarship and was on leave from the Department of Agriculture, Sydney, Australia

CHROMOSOMAL ABERRATIONS INDUCED BY AN ANIMAL VIRUS

By DR. BERGE HAMPAR and DR. SOLON A. ELLISON

Department of Microbiology, College of Physicians and Surgeons, Columbia University, New York

SEVERAL agents known to cause mutation of mammalian cells have also been shown to induce chromosomal aberrations[1–4] and it is generally accepted that such aberrations represent one stage of the mutagenic process induced by these agents No similar effect on chromosomes has been shown in the case of animal viruses, although there is evidence implicating viruses as possible mutagens which can produce heritable changes in one or more cell characteristics[5–8] This article describes the effect of herpes simplex virus on the cytology of chromosomes in a line of Chinese hamster (*Cricetulus griseus*) cells in tissue culture In this instance, infection produced cytological changes similar to those previously described as the result of treating mammalian cells with X-irradiation[1], alkylating agents[2,3], and bromodeoxyuridine[4]

The cell line used (designated *MCH*) appeared spontaneously in a bottle seeded with a normal 23-chromosome line of Chinese hamster cells received from Dr G Yerganian, and designated by him as 44–*FAF*–10 [9] No cellular proliferation had been evident for 8 days after seeding Since healthy-appearing cells were still present, the culture was trypsinized and passaged to several T-flasks Slow proliferation of the passaged cells was noticed during

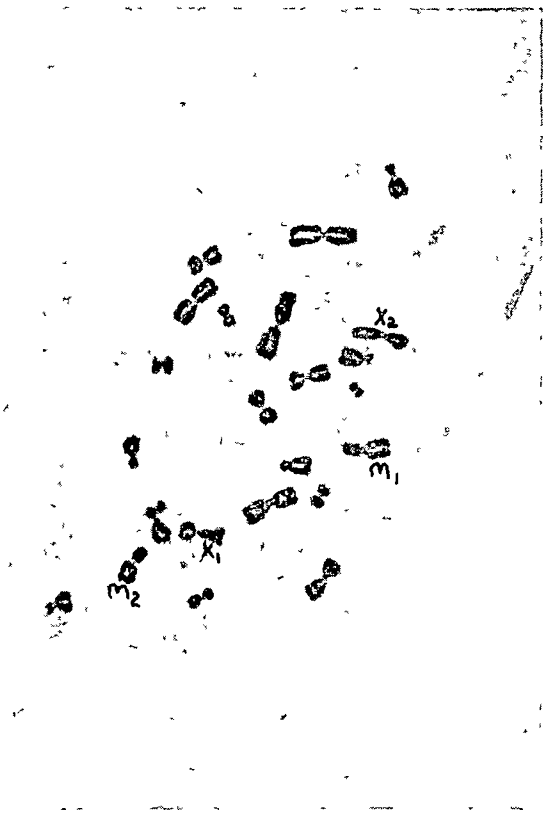

Fig. 1. Chromosomes of an uninfected *MCH* cell. M_1 and M_2 indicate marker chromosomes

several days, and these cells have now been maintained for 30 passages. Their generation time is at present similar to that of normal Chinese hamster cells (approximately 14 hr.). The *MCH* line is characterized as hyperdiploid, containing 23–28 chromosomes, and approximately 5 per cent of the cells are in the polyploid region (29 or more chromosomes). In comparison with chromosomes of normal Chinese hamster cells which have been examined in considerable detail[10-12], the unique characteristic of the *MCH* line is the presence of a marker chromosome not previously seen (Yerganian, G., personal communication). Fig. 1 shows the chromosomes of an uninfected *MCH* cell, in this instance containing two marker chromosomes differing slightly in their length. The sex chromosomes in the illustration are essentially normal, but slight variations in the X_1 and X_2 chromosomes have been observed. The marker chromosome is found in all cells regardless of chromosome number.

Cells were grown in a mixture consisting of Puck's medium (36 per cent), Hanks' balanced salt solution (37 per cent), N.C.T.C.-109 (6 per cent), lactalbumin hydrolysate (0.5 per cent), horse serum (10 per cent) and fœtal calf serum (10 per cent). The medium also contained penicillin (50 units/ml.) and streptomycin (50 μgm./ml.). All experiments were run in a humidified atmosphere containing 10 per cent carbon dioxide. For karyotype analysis, 2.5×10^5 cells were inoculated into 50 mm. Petri dishes containing 2 coverslips. Colchicine (1 μgm./ml.) was added after appropriate intervals and the cultures were incubated for an additional period, generally 6 hr. Carnoy's solution and acetocarmine were used for fixing and staining. Squash preparations were made according to the method described by Yerganian (in the press). In those experiments involving viral infection, the inoculum was added to the cells when the cultures were initiated. Mitotic indices and plating efficiency studies were carried out in parallel with chromosome analysis.

The strain of herpes simplex virus was isolated in 1952 on the chicken chorioallantoic membrane[13] and had been stored at − 70° C. until 1960, when it was adapted to growth in HeLa cells. The 49th and 50th tissue culture passages were used.

We have confirmed Yerganian and Gresser's finding (Yerganian, G., and Gresser, I., personal communication) that normal Chinese hamster cells are not susceptible to infection by herpes simplex virus. When the *MCH* line is inoculated with this agent, no cytopathic effect is observed nor do characteristic intranuclear inclusions develop, but chromosomal aberrations are seen during the first cell division following infection. Virus can be recovered from the supernatant culture fluids during two cell passages following infection—even though the cells are repeatedly washed free of released virus—as well as from frozen-thawed cells after three subsequent passages. Viral infection at the time of plating does not alter the cloning efficiency, which is approximately 80 per cent. Clones formed in the presence

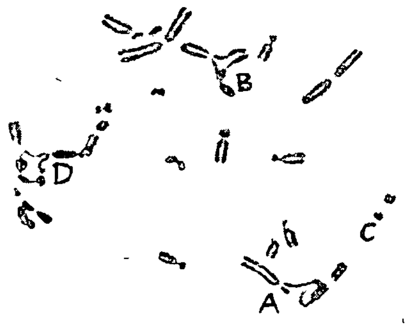

Fig. 2. Chromosomes of an infected *MCH* cell. *A*, chromatid break on chromosome 1 which has translocated to a medium-sized metacentric; *B*, chromatid exchange involving chromosome 2 and the X_1 chromosome; *C*, centromeric fusion of two telocentric chromosomes; *D*, chromatid separation and translocation involving the X_2 chromosome

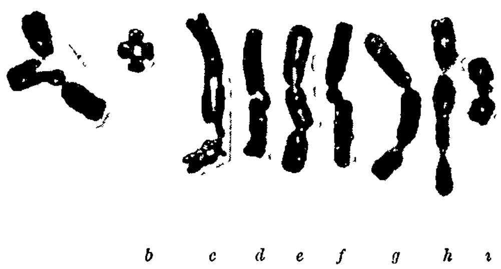

Fig. 3. Examples of chromosomal aberrations in infected *MCH* cells. *a*, chromatid break at the centromere of chromosome 2 showing terminal association with the short arm of the X_2 chromosome; *b*, reciprocal (chromatid) translocation involving two small metacentric chromosomes at their centromeric regions; *c*, chromatid deletion of chromosome 1 with segmental interchange; *d*, chromatid break at centromeric region of chromosome 1; *e*, *f*, chromatid break along chromosome 1; *g*, *h*, chromosome dicentric or exaggeration of secondary constrictions on chromosome 1; *i*, centromeric fusion of two telocentric chromosomes

of virus consist of moderately ballooned cells in contrast to the characteristically long and narrow fibroblastic cells seen in uninfected clones These results warrant the assumption that a type of carrier culture has been produced

Figs 2 and 3 illustrate the types of chromosomal changes produced by virus infection (We are indebted to Dr G Yerganian for his assistance in interpreting the karyotypes) Most aberrations occur at the centromeric and secondary constriction regions of chromosomes 1 and 2 as shown in Figs 2 and 3*a*, *c*, *d*, *e* and *f*, as well as at the centromeric regions of subtelocentric chromosomes, with the resultant formation of acentric fragments Where definitive breaks do not occur, exaggeration or elongation of centromeric and secondary constriction areas are evident (Figs 3*g* and *h*) Fusion at the centromeric regions of two chromosomes (Fig 3*i*) is seen infrequently

Table 1 presents a compilation of the chromosomal aberrations that result when cultures are infected at a multiplicity of one Chromatid breaks are common in infected cultures whereas uninfected controls and cultures inoculated with heat-inactivated virus show only chromosome breaks Translocations are recorded as to the number of cells, and these cells are not included in other categories Aberrations are not restricted to any particular karyotype, and are observed in cells bearing varied chromosome numbers Heat-inactivated virus shows no effect, as indicated in Table 1 Aberrations seem to be restricted to the metaphase of the first cell division following infection, even though virus is present during several subsequent passages The mitotic indices of infected and uninfected cultures show no significant variation, both reaching a maximum in approximately 40 hr after initiation of the cultures

Table 1 CHROMOSOMAL ABERRATIONS IN NORMAL AND VIRUS-INFECTED *MCH* CELLS

Age (hr) when colchicine added*	No of cells scored	Chromatid and chromosome breaks per cell	Accentuated secondary constriction or centromeric regions per cell	Percentage of cells with translocations
Infected				
2	102	0.18	0.07	3.9
14	200	0.23	0.08	9.5
40	196	0.21	0.12	4.1
72	218	0.09	0.007	0.0
Uninfected or inoculated with heat-inactivated virus				
2–72†	400	0.075	0.002	0.75

* Colchicine treatment lasted 6 hr except in the case of 2-hr -old cultures which were exposed to colchicine for 18 hr

† No variation with time observed in these cultures

The chromosomes of cells no longer releasing virus are now being examined in detail Preliminary work indicates that if chromosome variations are present after infection, they are not qualitative but rather quantitative or cryptostructural[14] The only variations noted thus far between infected and uninfected cells are based on slight morphological alterations which cannot in themselves be considered conclusive proof of induced mutation The fact, however, that virus infection does not result in any recognizable cell destruction and that a short-term carrier state can be established in the *MCH* line, indicates that the aberrations seen are non-lethal It is therefore possible that some permanent alteration in cellular characteristics has occurred

This work was supported by a research contract [*Nonr* 266(63)] between the Office of Naval Research and Columbia University, and by a grant from the Bristol-Myers Company One of us (B H) is a post-doctoral Research Fellow of the National Institute of Dental Research, National Institutes of Health

INFLUENCE OF THE AGE OF POLLEN AND STIGMAS ON SEX DETERMINATION IN HEMP

By REGINA LASKOWSKA

Institute of Soil Science and Plant Cultivation, Pulawy, Poland

PREVIOUS investigations on the influence of the age of pollen on sex determination in hemp have given conflicting results[1,2] The possibility of regulating the number of the male and female individuals in a population would have great practical significance For this reason investigations were carried out during 1955–60 concerning the influence of the time of storing of pollen as well as the age of stigmas on sex determination in hemp derived from Poland, a type intermediate between that of central Europe and central U S S R

Female plants of hemp, with different or similar ages of stigmas, were pollinated with pollen of determined age in the same doses Plants which were pollinated naturally were used as control series In the next generation the relations of sex were analysed in all the combinations In 1955 the age of stigmas was not taken into consideration The female flowers in full blossom, that is, with stigmas of different ages, were pollinated with pollen in three stages of ripeness (1) gathered from flowers immediately after dehiscence , (2) stored in uncovered Petri plates in free air for 6 hr , (3) stored in the same way for 12 hr In the experiment in 1956 both the ages of pollen and that of stigmas were known Female plants with stigmas 7–12 days old were pollinated with pollen (1) fresh, gathered immediately after opening of male flowers, (2) stored in uncovered Petri dishes in the laboratory for 24 hr The experiments were carried out in a greenhouse with artificial or space isolation The results are summarized in Table 1

The plants begin to blossom gradually on different nodes, for this reason the age of stigmas may be very different in the female flowers flowering at the same

control		1955/56	550	242	258	44 0	56 0	—	—	—	—	—
,,		1956/57	700	315	385	45 0	55 0	—	—	—	—	—
,,		1958/59	138	67	71	48 5	51 5	166	83	83	50 0	50 0

time It was observed that the hemps investigated began to bloom at the 7th or 8th leaf node (counting the cotyledon node as the first) On the basis of this observation, in the experiments of 1958 only the flowers at the 7th and 8th nodes were pollinated, that is, those which had stigmas 1–3 and 12 days old Pollination was carried out with fresh, and with 14–17-days-old, pollen In this experiment the mother plants were sown on the ground and covered with double sacks of dense fabric, while pollen was kept in a desiccator with calcium chloride Plants which were pollinated naturally were used as controls, but seeds were taken from the 7th and 8th node only Both in controls and in most of the combinations with fresh pollen the seeds were set normally , only in combinations with stigmas 12 days old and fresh pollen, and stigmas 12 days old with pollen 14–17 days old (Table 1), was the number of seeds considerably less, and consequently the number of plants in these series was relatively small

Nevertheless the results of these two series were also taken into account when the conclusions were drawn, since similar sex-ratios were observed in previous years

From Table 1 one may conclude that (1) the age of the stigma does not influence the direction of sex-determination in hemp, (2) depending on the period of storage, pollen has a certain influence on the numerical relations of male and female individuals of the given population

In the first and second generations a predominance of female plants occurred when pollination was carried out with fresh pollen (immediately after the beginning of pollen emission by the flowers and up to 6 hr afterwards) and when pollen was 14–17 days old In crosses which were pollinated with fresh pollen the number of female plants was about 2–11 per cent higher in the first generation and 13 per cent higher in the second than in the control series When pollination was performed with pollen 14–17 days old the majority of female plants in relation to the control series amounted to 20 per cent in the first generation and 5 per cent in the second Pollen 12 and 24 hr old did not cause any changes in the sex ratio, the results being identical with those obtained in the control series

The results of investigations suggest that (1) The rhythm of development of pollen with female tendency (x) and of that with male tendency (y) is different (2) It is possible that in pollen populations with male tendency a certain percentage of grains ripens later than those of the populations with female tendency. In consequence, a shift of direction of sex ratio towards the female side may occur in the populations of plants derived from pollination with young pollen (3) The preponderance of female plants after the pollination with pollen 14–17 days old may be evidence either of the frequent occurrence of longer duration of vitality of pollen with female tendency, or (and it means the same in the case of phenotypic observations) of shorter duration of vitality of some part of pollen with male tendency (4) The ratio of male plants to female plants near to 1 1 obtained in the populations derived from pollination with pollen 12 and 24 hr old may be due to equal quantities of pollen of both tendencies at this age and, in this case, to the random process of pollination

SIMULATED WAVE-RIDING DOLPHINS

By BYRNE PERRY

A. J. ACOSTA and TARAS KICENIUK

Hydrodynamics Laboratory, Division of Engineering, California Institute of Technology, Pasadena

THE explanation of the mechanism by which dolphins are able to ride bow waves of ships, or natural surf and wind-generated waves, has stimulated much discussion and controversy Since an excellent summary of previous research on the wave-riding problem has been given by Fejer and Backus[1], only a few remarks by way of review will be given here

Although dolphins had been observed riding on bow waves of ships many times over the years, Woodcock[2,3] published the first account which included considerations of the forces estimated to be required Shortly thereafter, Woodcock and McBride[4] undertook to explain in more detail the nature of these forces They found that a 200-lb dolphin submerged in sea water would have, at most, a net

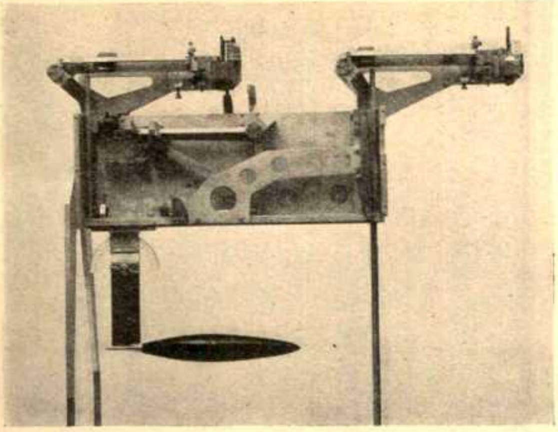

Fig. 1. The 'dolphin-like body' mounted on the 3-component force balance used in these experiments

weight of 9·2 lb. The component of this weight in the direction of the local flow was thus shown to be too small to overcome the expected viscous drag, unless the dolphin was in some manner able to maintain a laminar flow over its body-surface. The Reynolds number for these observations was $8 \cdot 4 \times 10^6$ based on body-length. For rigid bodies tested under many conditions it is known that at such a Reynolds number the boundary layer is almost certainly turbulent; hence, the conclusion would follow that the dolphin had achieved the surprising feat of maintaining a laminar boundary layer (and hence, very low drag) at a very high Reynolds number.

It was Hayes[5] who pointed out that it was the component of the total weight rather than the net weight in the direction of the local flow that provided the thrust. With this force available, there is no need to suppose the dolphin has a viscous drag appreciably lower than any other streamlined body moving at the same Reynolds number.

In spite of the lucid arguments set forth by Hayes, some workers remain unconvinced. Scholander's experiments in the open sea[6] convinced him that the Hayes explanation was not satisfactory. Scholander and Hayes[7,8] thereupon arrived at an impasse, with Scholander suggesting that further experiments be conducted under better-controlled conditions.

In discussing these considerations with Prof. Scholander, it occurred to us that the free-surface water tunnel in the Hydrodynamics Laboratory at this Institute could be used to help resolve this controversy.

Apparatus and Experimental Procedure

At tunnel operating speeds approximating 7 ft./sec., it is possible to establish a stable, standing wave in the working section of the free-surface water tunnel[9]. Such a wave was formed, and the simulated dolphin model (consisting of a streamlined body of revolution 2 in. in diameter and approximately 1 ft. long) was immersed in the wave and the hydrodynamic reactions were measured. The test body, strut support, and force balance assembly are shown in Fig. 1. Extensive force measurements had already been made on this body in previous investigations[10] using wind tunnel, water tunnel and drop tank facilities, and were therefore available for comparison. The configuration of this body, however, had been slightly modified for the present experiments by replacing the original tail and boom assembly with a shorter one. Also, an adjustable streamlined strut had been attached to this boom, thereby permitting the attitude of the test body to be determined within an angle of ½ degree.

Prior to starting the tunnel, tare forces were measured with the test body in air, at each of the angles of the test body used in the experiment. By means of an elevating mechanism, the balance and body assembly were lowered until the centreline of the body was at a depth of about 0·2 ft. The buoyant force acting on the body in still water was then measured. The tunnel was started and the standing wave established. Force readings at the two tunnel locations were made for angles of 0° and ±8° at various submergences.

Position 1 (Fig. 2) was located on the upstream slope of the wave, considerably ahead of the crest. It had been hoped that the body could be located somewhat farther downstream; but this could not be done easily because of interference with a tunnel structural member. Position 2 (Fig. 3) was in the trough of the wave. The water velocity in these tests was of necessity near the critical channel velocity, but varied locally with position along the wave. A miniature *HRS* current meter about ½ in. in diameter was used for measuring these velocities at the same longitudinal position and depth as the midpoint of the test body. These results are summarized in Table 1 as well as are some other conditions not described.

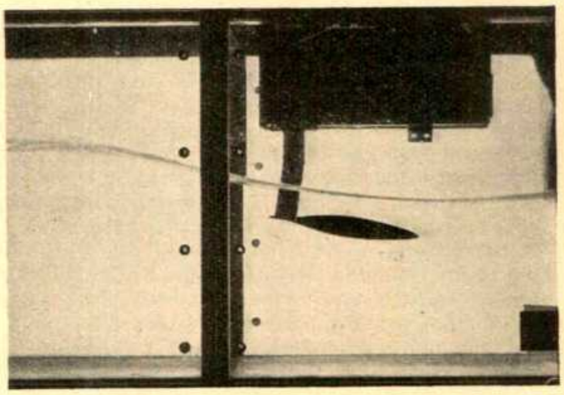

Fig. 2. 'Dolphin-body' located at tunnel position No. 1 on the forward slope of a standing wave. Net forward thrust = 0·007 lb. at a velocity of 7·02 ft./sec.

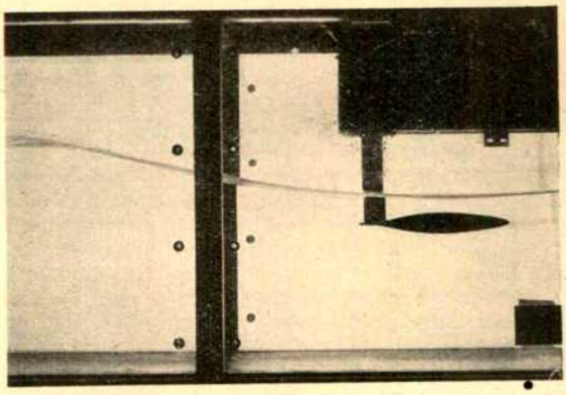

Fig. 3. 'Dolphin-body' located at tunnel position No. 2 in the trough of the standing wave. Net drag = 0·071 lb. at 7·24 ft./sec. Note the dye streak ahead of the model near the model centre-line

18	1	− 8	0·45	0·006	0·824	7·00	

* Negative values imply thrust.

Observations and Analysis of Results

When the test body was aligned with the slope of the water surface and submerged beneath the upstream slope of the wave in position 1, it was immediately apparent that a small, forward thrust between 0·007 and 0·011 lb. was measured (see runs 14–17). However, when the body was located in the trough of the wave at a similar submergence (runs 8, 9, 10) the body experienced a drag force ranging from 0·07 to 0·106 lb. These figures can be compared with the still-water buoyant force of 0·78 lb. to establish scale. Although no attempt was made to find the optimum location of the body with respect to the wave in so far as thrust is concerned, it is clear that a net thrust can be achieved with a rigid streamline body under even the gentle slope of the wave produced in the tunnel.

The observed thrust varies with depth and changes to a drag both when the body broaches and when the submergence exceeds about three diameters of the body. It should be remembered that the drag of the strut is included in these results so that the present results do not reflect the body drag alone. The submergence for least drag observed herein—about one body diameter—is roughly the same as that reported for dolphins in bow waves.

Further insight into the mechanics of the force system acting on the body is obtained by resolving the forces along axes parallel to and perpendicular to the local flow angle[5]. For example, for run 14 of Table 1 the resistance parallel to the local flow is 0·054 lb. and the force normal to the flow (or free surface) is 0·745 lb., with the estimated local flow angle of 5°. This latter force, perpendicular to the wave surface, can be regarded as an inclined buoyant force as mentioned by Hayes. These forces, it must be recalled, are hydrodynamic in origin and do not include the body-weight. Let it be supposed now that the self-propelling capability of a body, the weight of which is equal to that of the displaced fluid, is to be determined. This weight of 0·777 lb. resolved along the direction of flow must exceed the flow resistance of 0·054 lb. For the present example, this force is not only exceeded but there is also, in fact, a net propelling force of 0·013 lb. available. The forces are not precisely in equilibrium for this example; the body, if free, would tend to sink to a slightly greater depth, where the vertical force is seen to be larger.

The flow resistance of 0·054 lb. resolved along the local flow-angle is roughly comparable with the drag measured in the trough of the wave (run 8) and both are typical of viscous drag measurements in a turbulent flow[9,11]. Laminar skin friction is therefore seen not to be a necessary condition for bow wave-riding as was originally contained in the suggestion by Woodcock.

It is also interesting to observe that the vertical forces, both in the slope of the wave and in the trough, differ noticeably from the buoyant force in still water. This is thought to be due to a combination of two effects: the well-known repulsion experienced by a submerged body moving under an otherwise flat, free surface, and more important, the curvature of the local streamlines. Summary calculations have shown the contributions of the latter term to the lift force to be of the correct magnitude.

Conclusion

The mere existence of the measured forward-acting thrust on the test body in a wave demonstrates that a rigid body with turbulent flow can perform the wave-riding trick. Analysis of the measurements shows further that the force system is equivalent to a dynamic buoyant force perpendicular to the inclined wave surface and a resistance parallel to this surface. The dynamic buoyancy is approximately equal to the weight of the displaced liquid, while the viscous resistance is substantially equal to that measured on the body when not in the wave.

In spite of these incomplete experimental results, it appears inescapable that Hayes's arguments are substantially correct.

SPACE SCIENCE

Errors in Orbital Predictions for Artificial Satellites of Earth

SEVERAL workers[1-3] have carefully investigated variations in the accelerations of artificial satellites of Earth, but no one seems to have published a systematic study of the errors in orbital predictions. The results of such work[4] are presented in this communication. A stochastic model was constructed which takes into account fluctuations in atmospheric density, observational errors, and the correlations introduced by smoothing. Errors in actual predictions issued by the Vanguard Computing Center, National Aeronautics and Space Administration Computing Center, Smithsonian Astrophysical Observatory, and Naval Weapons Laboratory were also computed, for comparison with the theoretical model.

Table 1. ERRORS IN PREDICTION NEAR PEAK OF SUNSPOT CYCLE

Satellite	Dates	No. of predictions	$-dP/dn$ (min./rev.)	N (rev.)	E_0 (min.)	E Actual (min.)	E Theoretical (min.)
Explorer IV	1958	8	$2{\cdot}15 \times 10^{-3}$	165	0·024	3·2	3·3
Sputnik III	1958	7	$1{\cdot}32 \times 10^{-3}$	220	0·01	3·3	1·9
Vanguard I	Autumn 1958	20	$5{\cdot}5 \times 10^{-5}$	154	0·056	0·25	0·22
Vanguard I	Summer 1959	11	$2{\cdot}1 \times 10^{-5}$	154	0·056	0·13	0·097
Vanguard I	Winter 1959–1960	7	$6{\cdot}5 \times 10^{-6}$	154	0·056	0·062	0·061
Atlas-Score	Dec. 1958–Jan. 1959	1*	$2{\cdot}2 \times 10^{-2}$	271	0·3	67	74

* A single observation has no statistical significance. This case is included merely to show how large the error can be when the rate of change of period is large.

Table 2. ERRORS IN PREDICTION HALF-WAY BETWEEN SUNSPOT MAXIMUM AND MINIMUM

Satellite	Dates	No. of predictions	$-dP/dn$ (min./rev.)	N (rev.)	E_0 (min.)	E Actual (min.)	E Theoretical (min.)
Tiros II	Dec. 1960–May 1961	12	$3{\cdot}7 \times 10^{-6}$	250	0·08	0·12	0·08
Vanguard I	Oct. 1960–May 1961	12	$7{\cdot}4 \times 10^{-6}$	150	0·06	0·12	0·06
Transit III-B	Feb.–Mar. 1961	10	$1{\cdot}05 \times 10^{-2}$	22	0·04	0·74	0·50
Echo I	Oct–Dec. 1960	6	$6{\cdot}8 \times 10^{-4}$	145	0·04	4·4	3·3

The actual and theoretical errors in orbital predictions are given in Tables 1 and 2 and Fig. 1. Table 1 contains the errors in 1–2-week predictions made near the peak of the sunspot cycle. Fig. 1 presents the same data graphically. Table 2 shows the errors in predictions half-way between sunspot maximum and sunspot minimum. In Tables 1 and 2, N is the number of revolutions predicted, beginning at the centre of the smoothing interval. The smoothed rate of change of period is dP/dn (min./revolution). The root-mean-square prediction error, E (min.), includes the contributions of observational errors and drag fluctuations. The theoretical prediction error caused by observational errors alone is designated by E_0.

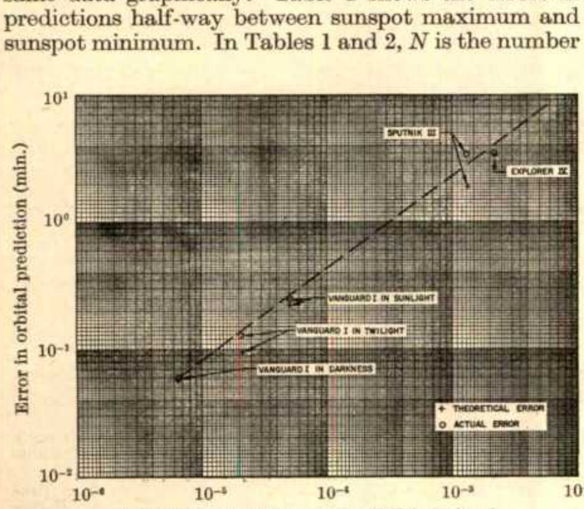

Fig. 1. Errors in orbital predictions running for 1–2 weeks

It is interesting to note that observational errors were the principal cause of errors in orbital predictions for only one of the cases shown in Fig. 1, that of *Vanguard I* with its perigee in darkness (winter 1959–1960). In all the cases shown in Fig. 1, the prediction errors attributable to observational errors were smaller than the total error for *Vanguard I* in darkness. If the errors in the predictions had been caused only by observational errors, then the prediction errors would have been independent of the smoothed rate of change of period. A detailed discussion of the theory and the method of calculation is given in ref. 4.

ASTROPHYSICS

Secular Variations of Short-lived Sunspots

LARGE secular variations have been found in short-lived sunspots as recorded in "Sunspots seen on one Day Only" of the Greenwich Photo-Heliographic Results, 1879–1957. The 11-yr. period often appears like a subsidiary perturbation.

A pertinent example is seen in Fig. 1, which shows the ratio K between the number of one-day spots at less than 65° from the central meridian, and the number of spots seen throughout two days or more. In Fig. 2 is plotted the number of one-day spots without umbra as a percentage of the total number.

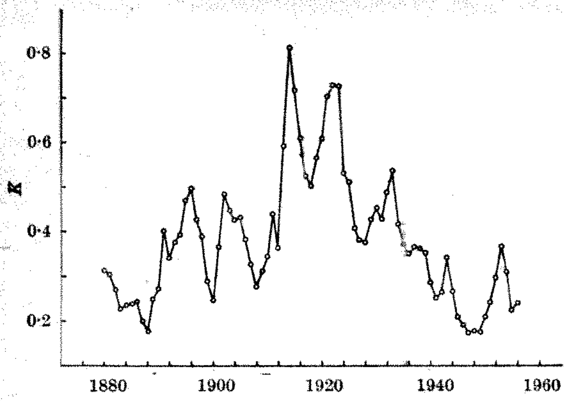

Fig. 1. Sliding 3-yr. mean for the period 1880–1956 of the ratio between the number of one-day spots and the number of spots observed throughout two or more days

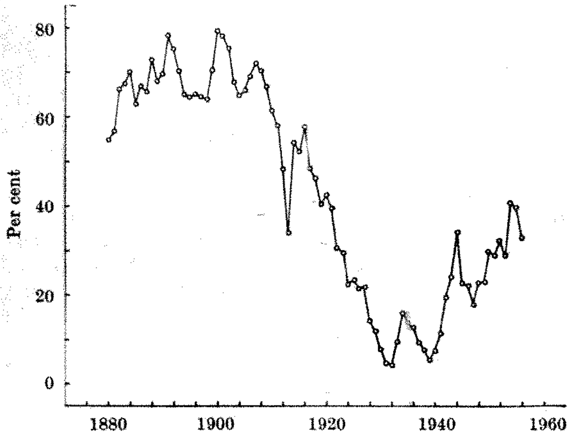

Fig. 2. Sliding 3-yr. mean for the period 1880–1956 of the number of one-day spots without umbra as a percentage of total spot number

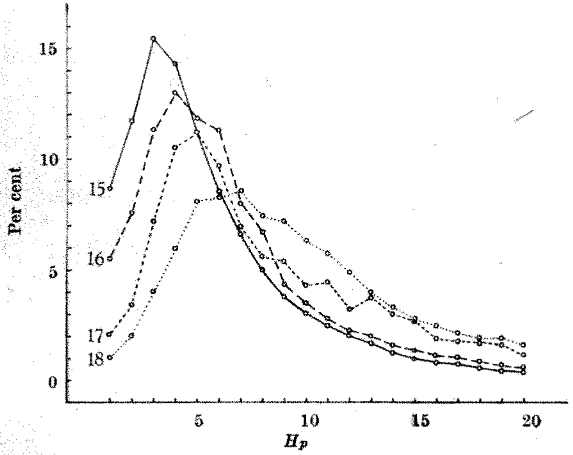

Fig. 3. Sliding mean of the number of one-day spots with determined total area as a percentage of total numbers for cycle 15 (1914–24), cycle 16 (1922–34), cycle 17 (1932–45) and cycle 18 (1942–54)

The frequency distribution with respect to area (both total area and area of the umbra) varies from one cycle to the next, and in such a way that the frequency maximum decreases with increasing area. This is shown in Fig. 3, which gives the smoothed frequency distribution with respect to total area for the solar cycles 15–18.

In an earlier paper[1] secular variations were found in the relation between magnetic field-strength H and total area A_p of sunspots, $H = a . \log A_p + b$, where a and b are coefficients that vary systematically from one cycle to the next. A connexion was predicted between the secular variations and variations in number and distribution of area of short-lived spots. This is borne out by the present investigation, which shows a marked correlation between the coefficients a and b and the mean values of K and A_p for one-day spots in the various cycles.

RADIOPHYSICS

Coincidence of the Explosive Phase of Solar Flares with 10·7-cm. Solar Noise Bursts

The observational evidence of an explosive phase in the development of the solar flare, as reported by Athay and Moreton[1], is of great interest. This phase appears after the commencement of the flare, is well defined, and thus provides a stage in the evolution of certain flares which may be of significance for examination of flare-related phenomena, such as solar noise bursts, etc. The Athay and Moreton paper lists eleven selected flares with 'explosive' phases. Two of these flares occurred outside the normal observing period at Ottawa, but the remaining nine can be compared with 10·7-cm. solar noise bursts observed at Ottawa. These cases, while few in number, sharpen the already well-established close relationship between flares and 10·7-cm. radio bursts which have been derived from other work done on the Ottawa data[2].

The relationships between the starting times of the flare, the explosive phase (as given in Table 1, of ref. 1) and the starting time of the 10·7-cm. burst (as given in the "Tabulation of the 10·7-cm. Outstanding Occurrences" published in the *CRPL-F*, Part *B*. *Solar-Geophysical Data*) are shown in Fig. 1. In order to provide identification, each radio event has been assigned the same letter as the associated flare event. The upper histogram shows the distribution of the difference in time of start of the flare and of the explosive phase; the lower histogram shows the dis-

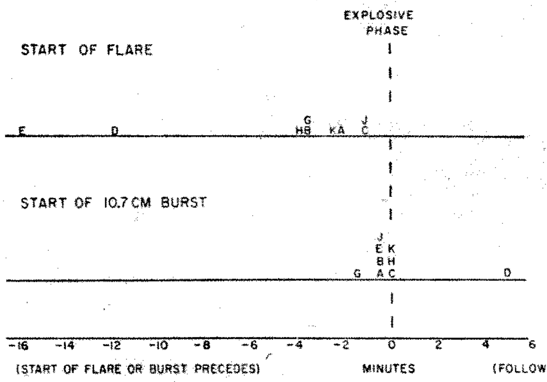

Fig. 1. Upper, distribution of the difference in time of start of the flare and of the explosive phase; lower, distribution of the difference in time of start of the 10·7-cm. burst and the explosive phase of the flare

tribution of the difference in time of start of the 10 7-cm burst and of the explosive phase of the flare. Comparison of the two histograms shows that, on the average, the start of the 10 7-cm burst precedes the explosive phase of the flare by approximately 1/2 min (excluding event *D*) whereas the start of the burst follows the commencement of the flare by approximately 2 min (excluding events *E* and *D*).

The coincidence of the time of start of the burst and the time of the explosive phase of the flare is not altered significantly when the criterion used to determine the start of the burst is examined. Burst commencement is that time when the rising flux has departed from the steady background-level by an amount equal to the residual receiver noise. In each of the nine cases examined here, the bursts are of the impulsive type, with a well-defined and rapid increase of emission from the steady background to a peak. Variations in interpretation and timing errors could introduce an uncertainty in the time of the start of the bursts of no more than ± 1/2 min.

Examination of the time profile of the 10 7-cm burst shows that there are two basic types of bursts: the impulsive burst, and the long-enduring burst (gradual rise and fall)[3]. As mentioned above, the bursts which are here associated with the explosive phase of the flare are all of the impulsive type. They are all, also, of more than average intensity. It may be of some significance that, in every case but one, the impulsive bursts are superimposed on long-enduring enhancements of radio emission of lesser intensity, and that in the one exception the occurrence of sunset precludes any observation.

The occurrence of an impulsive burst on a long-enduring enhancement is regarded as a single composite event from the frequency with which the association appears. In the large number of cases which have been observed, the separation of the commencements of the impulsive burst and the long-enduring enhancement range from a few minutes to several hours. In the extreme, when the two bursts presumably start at the same time, two types of profiles have been observed in the resultant composite event, and have been classified differently in the published 10 7-cm. burst data. When the maximum of the long-enduring burst appears after the occurrence of the impulsive burst, the composite event is classified as a long-enduring burst with the impulsive burst superimposed on it. However, when the impulsive burst is followed by a long-enduring enhancement which shows only a steady decline, the event is classified as a single impulsive burst with a post-burst increase.

In the case of the nine radio events associated with the flares with explosive phases, both of these types of composite events have appeared. In cases *D* and *K*, the impulsive bursts are superimposed on long-enduring bursts which commence 23 min before the impulsive event, and continue for approximately 1 hr after the end of the impulsive burst. Burst *D* is the only impulsive feature in this composite event, but burst *K* is the third and most intense, by a factor of 3, of a group of three impulsive features in this composite event. Radio event *H* is a period of irregular activity in which a great number of impulsive events of various intensities appear superimposed on an elevated background. The most intense of these impulsive events has an intensity which is 17 times greater than the next largest of the superimposed features, and it is this intense impulsive feature which corresponds in time with the explosive stage of the flare. The period of irregular activity starts 6 min. before and ends approximately 30 min after this impulsive burst. In case *J*, sunset coincides with the final decline of the impulsive burst, and, while no long-enduring enhancement of emission was in evidence just prior to the burst, it is impossible to know whether any enhancement followed it. In all the other cases, *A*, *B*, *C*, *E*, and *G*, the impulsive bursts are followed by relatively long-enduring enhancements of emission of much less intensity (post-burst increase).

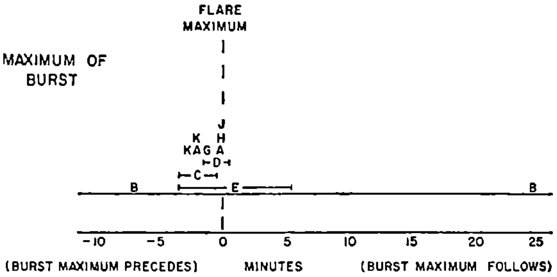

Fig 2. Distribution of the difference in time of 10 7-cm burst maximum and the time of flare maximum

The comparison of the time of burst maximum with the time of flare maximum is shown in Fig. 2. In the case of complex bursts, the times of both maxima are indicated by the letter identifying the event. In the cases where the burst produced off-scale readings and the maxima were not recorded, the off-scale period is indicated by a line. Although this histogram shows more scatter than that of the start of the bursts in relation to the explosive phase, it indicates that burst maximum is reached shortly before flare maximum in general.

The preceding detailed analysis involving a group of flares selected for the explosive phase in their evolution shows that the time of start of the 10-cm burst coincides with the explosive phase rather than the commencement of the flare, and these bursts, without exception, are of the impulsive type. A second type of 10-cm burst, the long-enduring burst (gradual rise and fall), cannot be directly related to this feature. This suggests that it is related to some other feature in the evolution of the flares.

OCEANOGRAPHY

Sea Surface Temperature in Coastal Waters of the British Isles

MR. A. J. LEE has recently commented[1] on my paper dealing with variations of sea surface temperature in coastal waters of the British Isles. He points out that I made no mention of the part played by currents in determining the winter pattern of sea surface temperature. I was, however, primarily concerned with the *shape* of the isotherm patterns. The presence of the relatively shallow water of the Dogger Bank area will, in itself, ensure that the pattern will consist of two tongues, although the level of temperature of these tongues will be largely determined by the strength of the currents mentioned by Mr. Lee.

Mr. Lee also criticizes the statement that the English Channel is isothermal or very nearly so throughout the year. Taking this statement in isolation, the criticism is fully justified, but it was intended to be taken as a comment on Fig. 1(*b*), which shows the mean temperature profiles at a position (49° 49′ N., 02° 33′ W.) towards the middle of the English Channel. Perhaps this should have been made clearer in the text.

I did not discuss the accuracy of the observations because the paper was written as an aid to local weather forecasting, and for this purpose an accuracy of ± 0.5° C. is adequate. Most of the sea temperatures used were obtained by the bucket method, and it is generally recognized that the above-mentioned standard of accuracy can be obtained by this method, if the readings are taken with reasonable care. Measurements of sea temperature made recently on Ocean Weather Ship *Monitor* by a thermistor, supplied by the Fisheries Laboratory, Lowestoft, and floated astern of the ship, steaming slowly at about 2 knots or when stopped 'on station', at a distance of 10 m., show that the differences from the bucket measurements rarely exceed 0.5° C. (only 1 occasion in 34 over a period of four days). There is always a danger of much larger errors of reading, for example, 5°, but as shown in my paper these can be readily distinguished if the sea temperature isotherms are drawn intelligently.

PHYSICS

X-Ray and Neutron Diffraction Examination of *p*-Diphenylbenzene

The crystal structure of *p*-diphenylbenzene was first determined by Pickett[1], using projection X-ray diffraction techniques. Because of the considerable theoretical interest in the bond-lengths of conjugated carbon-carbon bonds[2,3] a refinement of the structure has been commenced, using full three-dimensional X-ray and two-dimensional neutron diffraction techniques.

The refinement of the data on *h*0*l* neutron diffraction projection has given some interesting results, which are discussed here. The neutron intensity data were collected on the single crystal spectrometer installed at the *Hifar* reactor at the Australian Atomic Energy Commission Establishment. The intensity of the neutron beam from the (1,1,1) plane of a copper monochromating crystal was 140,000 counts/sec./cm.^{2}, when set to reflect neutrons with a wave-length of 1.0015 ± 0.0005 Å. The intensities at all the *h*0*l* reflexions out to sin θ/λ = 0.8 Å^{-1} were measured, and of the 248 possible reflexions, 139 had intensities sufficiently greater than the incoherent scattering background. By comparison, in the *h*0*l* projection in the X-ray case, 107 of the 140 possible reflexions out to the copper $K\alpha$ limit were obtained.

The *h*0*l* projections of both the neutron and the X-ray structure have been refined simultaneously. This has enabled a comparison to be made of the relative power of the two methods. The X-ray structure determinations showed that the thermal motions of a number of the atoms in the molecule were markedly anisotropic. Significant peaks were found in the difference synthesis at positions corresponding to the hydrogen atoms, when these were not included in the structure factor calculation. From this synthesis approximate positions of the hydrogen atoms could be determined. The resolution obtained was poor, however, there being considerable overlapping of the features due to thermal anisotropy with those caused by hydrogen atom contribution. Consequently, an accurate evaluation of the thermal parameters and the positions of the hydrogen atoms was not possible. The corresponding neutron diffraction projection showed much better resolution and confirmed the X-ray observations. The atomic peaks in the Fourier synthesis[4] (Fig. 1), based on the neutron diffraction data, are well resolved. The form of the peaks gives clear indications of the extent of the anisotropy in the thermal motion of the atoms. The negative peaks corresponding to the hydrogen atoms are well resolved. This has led to an accurate determination of their positional parameters.

Certain interesting features of the structure are obvious from an examination of the neutron diffraction Fourier synthesis. First, there are significant deviations of some of the atoms from their normal positions so that the carbon skeleton of the molecule is slightly distorted, presumably for packing considerations. Each of the benzene rings has its normal configuration, but the two end rings are out of parallel with the central ring by approximately 1° 30′ (Fig. 2). Secondly, several of the hydrogen atoms are distorted from their normal positions due to steric hindrance within the molecule. Thus the hydrogen atoms attached to the C_1 and C_5 atoms (Fig. 2) are displaced in directions which increase the distance between them. This is in accordance with expectations, for if they occupied their normal positions they would be only 1.8 Å apart, whereas the

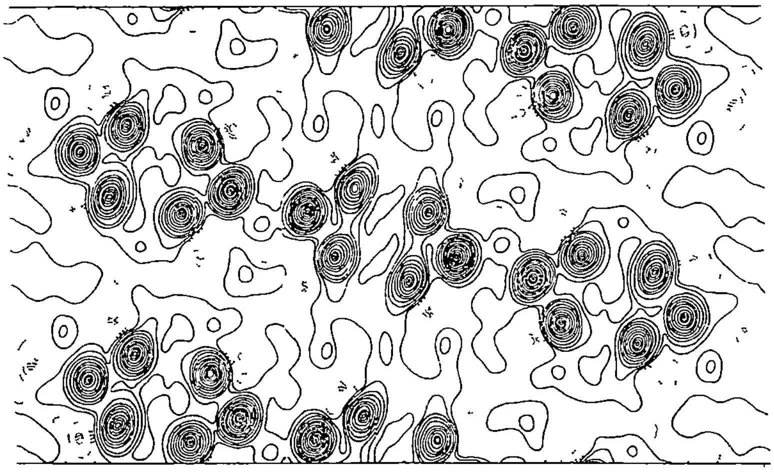

Fig. 1. A Fourier projection on the (010) plane of *p*-diphenylbenzene at room temperature based on neutron diffraction data. Contour intervals are in arbitrary units. Full lines are positive, broken lines are negative contours

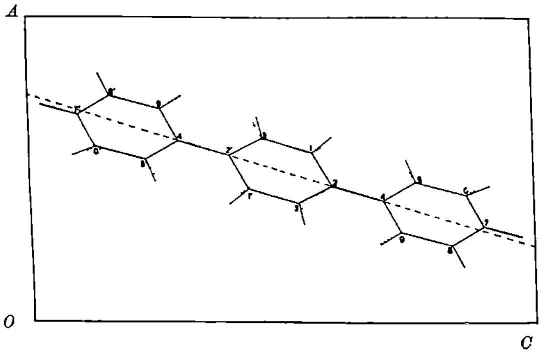

Fig 2 Atomic positions in the Fourier projection of *p*-diphenylbenzene Full lines are the undistorted C—H bonds

sum of their Van der Waals radii is 2 4 Å The equivalent pair of hydrogens attached to the C_3 and C_7 atoms is similarly displaced

It is also possible from work on the thermal parameters to deduce in projection the predominant modes of thermal vibration within the molecule The C_2 and C_4 atoms have thermal motions considerably less in magnitude than those of the remaining carbon atoms The motions of all the atoms are markedly anisotropic, the direction of maximum vibration being perpendicular to the long axis of the molecule It may be shown from this that two modes of vibration predominate The first appears in projection as an oscillation about the centre of gravity of the molecule, and the second is an oscillation about the long axis of the molecule, that is, the line joining the C_7 and $C_{7'}$ carbon atoms The presence of the former mode confirms the recent suggestions of Bacon and Curry[5] that the outer benzene rings in mòlecules of this type have considerably more freedom of movement than the inner ones

The X-ray and neutron diffraction work is continuing, and a full report will be published elsewhere

The first three authors are indebted to the Australian Institute of Nuclear Science and Engineering for the generous financial assistance that has made the neutron work possible The co-operation and assistance of the *Hifar* reactor staff is gratefully acknowledged

Energy-Level Model for High-Resistivity Gallium Arsenide

ALTHOUGH gallium arsenide is usually prepared with low resistivities (< 1 ohm-cm), it has also been prepared for several years with very high resistivities (> 10^6 ohm-cm) This latter material can be produced by zone refining[1], by the addition of impurities such as oxygen[1], or under growth conditions where the main shallow donor, silicon, is reduced below roughly one part per million[1] To explain the occurrence of high-resistivity gallium arsenide, Welker[2] suggested that the donors and acceptors are built into the lattice in pairs More recently, Allen[3] has termed this material 'semi-insulating', and claims that the existence of *n*-type high-resistivity material requires that there be a very high degree of compensation between the shallow donor and a deep acceptor He also states that because of the frequency of occurrence of high resistivities, some mechanism of automatic compensation must be operative Later, to explain gradual transitions in resistivity along floating-zone refined ingots, Gooch *et al* [4] have shown that a wide range of resistivities can still occur even on assuming a high degree of automatic compensation However, according to their model, the degree of automatic compensation must vary along the ingot, yet cannot vary too much otherwise *p*-type material is predicted, which is not observed

A three-energy-level model is proposed here which explains the existence of high-resistivity material without requiring that there be a high degree of compensation, and therefore no need for invoking the occurrence of automatic compensation Similar to the above model[4], a wide range of resistivities will be shown to be possible The energy-level scheme is shown in Fig 1, where N_D is the density of shallow donors, N_{DD} the density of deep donors, and N_A is the density of acceptors It is easily seen that high-resistivity material will result when $N_A > N_D$ and $N_{DD} > (N_A - N_D)$ These conditions are not very restrictive, and explain why high-resistivity gallium arsenide can occur so frequently For example, for a given concentration of N_{DD}, high resistivity will result when N_D is removed at a faster rate than N_A, as possible in zone refining, or else that the concentration of N_A is increased, which might occur when oxygen is added Of course, when N_D is somewhat greater than N_A, the material is low-resistivity *n*-type, and the N_{DD}-levels are neutral It is also seen that so long as $N_{DD} > N_A$, *p*-type material will not occur

The model of Fig 1 can be treated simply mathematically assuming that the activation energy of the deep donor is E_d, and that of N_D and N_A is zero, however, relaxing these latter restrictions does not detract qualitatively from the results Then the electron concentration, n, is given by

$$n = \frac{N_c \, N_{DD} \exp \left(-E_d/kT\right)}{2n + N_c \exp \left(-E_d/kT\right)} + \frac{n_i^{\,2}}{n} - (N_A - N_D) \quad (1)$$

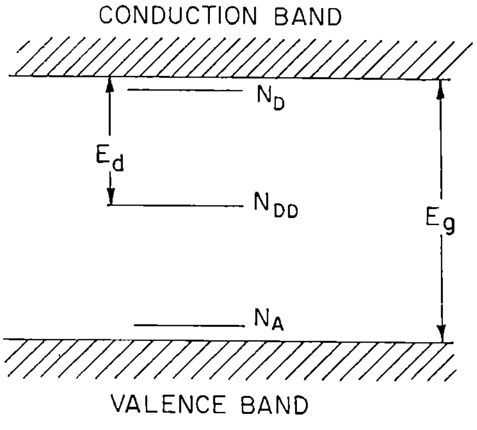

Fig 1 Energy-level diagram for the model

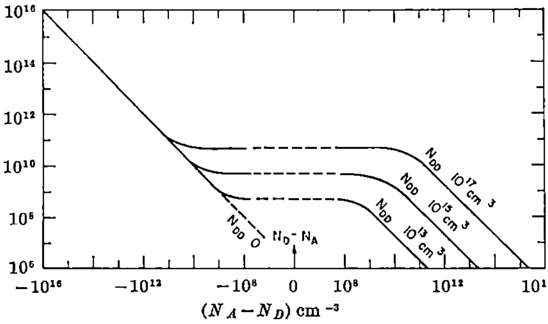

Fig 2 Variation of electron concentration, n, with $(N_A - N_D)$ at room temperature for various values of N_{DD}, with $E_d = 0\ 76$ eV

where n_i is the intrinsic electron concentration, and N_c is the effective density of states in the conduction band

A value for E_d of 0 76 eV has been deduced by Gooch *et al* [4] Using this value, the quantity N_c exp $(-E_d/kT)$ in the denominator of equation (1) can be neglected for n-type samples and then equation (1) can be easily solved for n The variation at room temperature of n with $(N_A - N_D)$ is shown in Fig 2 for $N_{DD} = 10^{13}$, 10^{15}, and 10^{17} cm^{-3}, using $N_c = 6\ 3 \times 10^{17}$ cm^{-3} and $n_i^2 = 1\ 1 \times 10^{13}$ cm^{-3} The results of this model are quite similar to those of Gooch *et al* [4] in that a wide range of resistivities can occur, and further three conductivity-ranges are predicted At high electron concentrations, the Hall coefficient should be independent of temperature, at very low electron concentrations, the activation energy deduced from Hall effect measurements should give E_d, however, only in the case of extremely close compensation where $N_D \approx N_A$ should the activation energy be $E_d/2$, since in this range the deep donor is effectively uncompensated

A donor located at the centre of the energy band gap of gallium arsenide has been detected by thermally stimulated current measurement[1,5], and has been found, where experimentally feasible, in every crystal to date at densities of 10^{16} cm^{-3} or greater From Fig 2, it can be seen that the electron concentrations will be between 10^{6} and 10^{8} cm^{-3} for values of $(N_A - N_D)$ in the range from 2×10^{15} to 2×10^{13} cm^{-3}, which can easily occur as the shallow donor concentration is reduced This would also explain why there is almost no p-type gallium arsenide produced in undoped growth of gallium arsenide, but instead why usually either very high or very low resistivity n-type material is found Actually, thermally stimulated current measurements[1,5] have also shown the presence of other deep donors with shallower levels than 0 76 eV In this case, the three-level model is an over-simplification, and one would expect that the variation of Hall coefficient and conductivity with temperature would exhibit intermediate energy-levels, especially below room temperature, and this has already been observed[5]

Conductivity versus temperature slopes have been measured in n-type gallium arsenide with activation energies greater than half the band gap, that is, as large as 0 8 and 0 9 eV (C Hilsum, private communication, R H Bube, private communication) This behaviour is explicable on the present model In equation (1), it can be shown that at room temperature and above, for $N_{DD} > 10^{11}$ cm^{-3} and for $E_d \gg 0\ 8$ eV, both n_i^2 and the term N_c exp $(-E_d/kT)$ can be neglected Then so long as $(N_A - N_D)^2 \gg 2\, N_C\, N_{DD}$ exp $(-E_d/kT)$, n will vary as

$$n = \frac{N_C N_{DD}}{2\,(N_A - N_D)} \exp\,(-E_d/kT) \qquad (2)$$

The above condition is quite easily met Typical values could be $N_{DD} = 5 \times 10^{16}$ cm^{-3}, $N_D = 10^{12}$ cm^{-3}, and $N_A = 10^{13}$ cm^{-3}, and the sample will still be n-type It is also interesting that, depending on the magnitudes of $(N_A - N_D)$ and N_{DD}, a sample of gallium arsenide might never become intrinsic, and can exhibit a conductivity or Hall constant versus temperature slope greater than the intrinsic slope up to the melting point

Finally, it should be noted that the distinction drawn by Gooch *et al* [4] between 'semi-insulating' gallium arsenide, and 'high-resistivity semiconducting' gallium arsenide prepared by diffusion of copper into low-resistivity material[6], is non-existent in principle on the present model, since the concept of automatic compensation has not been invoked

We are indebted to Dr R H Bube for helpful discussions, and to Drs Gooch, Hilsum and Holeman for placing their paper at our disposal prior to publication This work was sponsored by the Electronics Research Directorate of the U S Air Force Office of Aerospace Research under contract

GEOLOGY

Natural Glass from beneath Red Clay on the Floor of the Atlantic

During April and May 1961 on a cruise of the R V *Chain*, a programme of coring deep-sea sediments from the Atlantic for geochemical investigations was conducted At 19° 23′ N, 40° 53′ W a modified Kullenberg corer was lowered through 4,430 m of water to the summit of a rise on the ocean floor The topography of the sea bed in this region is irregular, but between the hills and rises the average depth is approximately 4,900 m At the point where the corer struck the sea bed the surface sediment is a red clay, but no sediment core was obtained since at a very short distance below the surface the red clay is underlain by solid material The corer struck and broke the surface of this solid material, a fragment of which was recovered in the pilot corer, together with the overlying red clay From the position of the solid fragment in the pilot corer the thickness of the clay can be estimated to be not more than 38 cm The solid fragment is a very dark brown, almost black natural glass of irregular shape, but with approximate dimensions 3 cm × 2 5 cm × 1 3 cm Two faces of the fragment were freshly broken surfaces On two other faces a thin (1 mm) zone of devitrification occurs with small areas of manganese deposition on the outer surface The two other faces appear to be natural fractures Internally the fragment contains small irregular cavities about which slight devitrification has also occurred When collected the fragment showed a marked tendency to disintegrate into smaller fragments, a consequence, no doubt, of the impact of the corer on the brittle glass Red clay containing broken shards of the same glass was found adhering to the piston of the main corer, and it is likely, therefore, that the glass formation is too extensive to be interpreted as a boulder contained within the red clay It is believed to represent the solid surface on which the overlying sediments rest So far as is known this is the first sample collected of solid rock indisputably from below the sediments of the deep Atlantic

The glass fragment when collected weighed approximately 18 gm Part of it was crushed and natural glass fragments hand-picked from devitrified material for chemical analysis Examined optically these glass fragments appear homogeneous without crystallites, microlites or any other crystallization phenomena The chemical composition of this glass is quite remarkable, namely (percentages), SiO_2 25 81, Al_2O_3 19 35, TiO_2 2 02, Fe_2O_3 15 05, FeO 0 63, MnO 0 15, MgO 1 29, CaO 1 25, Na_2O 1 68, K_2O 0 89, H_2O 31 02, P_2O_5 0 08, Cl_2 0 97, uncorrected total 100 19 per cent, less 0 for Cl 0 22 per cent, corrected total 99 97 per cent It is quite different from compositions of natural igneous glasses from the continental regions of the world The high chlorine content suggests contamination with sea salts However, the fragments analysed were hand-picked from the interior of the larger fragment collected, and such a high chlorine content, equivalent to 1 6 per cent sodium chloride, cannot be attributed to surface contamination by sea water during collection The high water content also suggests contamination with sea water Attempts to determine the distribution of the water between loosely bound positions (H_2O-) and tightly bound positions (H_2O+) did not meet with success The loss in weight on heating the powdered glass for 20 hr at 108° C corresponded to 22 18 per cent of the total powder, but this figure slowly rises with continued heating Loss of water appears to be accompanied by crystallization of the glass so that any H_2O- figure determined does not correspond to the original material Thus the total H_2O figure has not been broken down into H_2O+ and H_2O- The very high Fe^{+++}/Fe^{++} ratio suggests that the material was hydrated while still in a molten condition, supporting the view that the water content of this glass is original, despite being so much greater than the water content of silicate glasses produced experimentally in the laboratory

A more extensive account of the properties of this glass and its possible origin will be published elsewhere Meanwhile we urge oceanographers to make further attempts to collect samples from the subsediment surface of the Atlantic floor in order to demonstrate whether this first sample is truly representative of that surface or merely an unusual type of limited distribution

Grateful acknowledgment is made to all aboard the R V *Chain* for help in the coring operations and particularly to R G Leahy, P L Sachs and G L Erlanger This work was supported by the U S Office of Naval Research under a contract with the Woods Hole Oceanographic Institution

Ultrabasic Liquids

FOR a number of years we have been investigating the problem of ultrabasic rocks with particular reference to evidence for and against the existence of ultrabasic liquids[1,2] We believe that our published results have largely established their existence and this has been further substantiated by Wyllie[3], and by Clark and Fyfe[4] Although Clark and Fyfe chiefly confine the application of their experimental results to what may be broadly termed the serpentinite problem, their conclusions have a very restricted validity if it is implied that serpentinites are the only type of ultrabasic rock which could have been mainly or wholly liquid In the ultrabasic rocks investigated by us most of the olivine is not serpentinized

The results of our recent investigation of picritic and peridotitic rocks add further support to the existence of ultrabasic liquids, but at the same time have revealed certain complicating factors the significance of which has yet to be evaluated The principal purpose of this communication is briefly to record and discuss some of these results

In West Greenland and the Scottish Hebrides we have made an extensive and detailed examination of marginal phenomena in what is by far the best developed series of ultrabasic (picrite and peridotite) minor intrusions within our knowledge As recorded in ref 2*a*, the degree of contact metamorphism is very variable and has no apparent relationship with the size of the intrusion To the evidence of high temperature on Soay[3] we can now add similar evidence from the Island of Scalpay in Skye and from Ubekendt Ejland in West Greenland On Scalpay, a picritic intrusion 3 ft in average thickness has fused xenoliths of a very quartzose sandstone to a clear glass (Fig 1) The picritic intrusion at Igdlorssuit on Ubekendt Ejland, where it is 10–12 ft thick, has largely liquefied the marginal 3–6 in of the contiguous zeolitic olivine-rich, basaltic lava (Fig 2), the liquefaction possibly having been facilitated by the fluxing action of water derived from zeolites But in the case of many otherwise similar ultrabasic minor intrusions, and in parts of the Soay, Scalpay and Igdlorssuit intrusions already mentioned, the effects of contact metamorphism are so slight that much lower temperatures are apparently implied One can only infer that in such cases some factor other than the inward diffusion of water, suggested by Clark and Fyfe, has been responsible for the relative lack of thermal metamorphism In seeking an explanation, it seems reasonable to refer to the manner and mechanism of emplacement of these intrusions The differences between their contact effects may in fact be due not

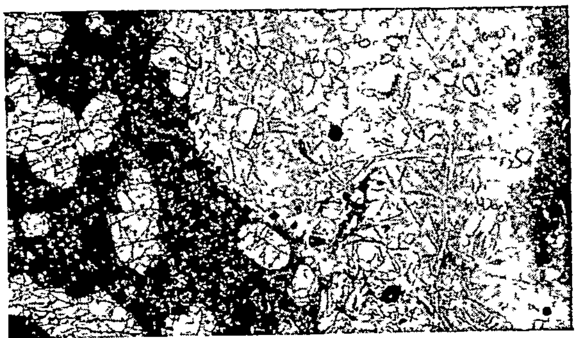

Fig 1 An ultrabasic contact (containing olivine phenocrysts) with a sandstone xenolith (containing small quartz relicts and acicular orthopyroxene) largely fused to form a clear glass (× 10)

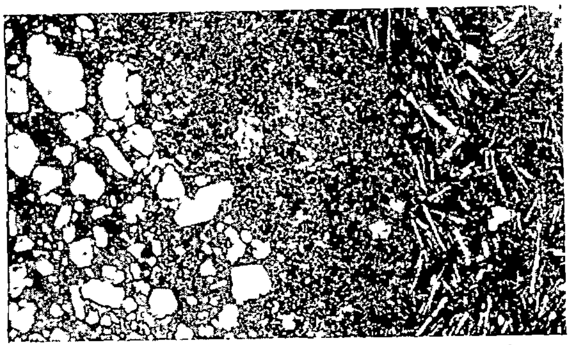

Fig 2 A later ultrabasic contact (containing non-skeletal olivine pheno-crysts) with rheomorphic, fused lava mixed with an earlier ultrabasic contact facies (containing skeletal olivines) (× 3)

to differences in the temperature of the intruding magma, but to differences in the period of time during which the adjacent country rocks were maintained at similar temperatures, the total heat effect at any one point being dependent, among other things, on the amount of magma that has passed that point and its rate of movement Variation within individual intrusions cannot be explained on this basis, but if ultrabasic magma, intruded at high temperature at one point, cooled and partially crystallized there before being translated to another position in relation to the country rock, it might well have much less thermal effect in its new position

Variability in the ultrabasic contact facies might be explicable by mechanisms similar to the above Development of skeletal olivines in the selvages of some intrusions, but not in others, could be accounted for by differences in rate of flow of magma In cases, such as those on Ubekendt Ejland (where ultrabasic selvages in which all the olivines are skeletal give place when traced laterally to selvages in which the olivines are predominantly non-skeletal), the second mechanism, namely cooling and partial crystallization at one point followed by translation to another, could apply In this way, the original, relatively quickly-congealed selvages with skeletal olivines could be dispersed and replaced by selvages characterized by non-skeletal phenocrysts (Fig 2) This does not diminish the significance of the development of skeletal olivines, which constitutes a much more common characteristic of ultrabasic contact facies than formerly suspected[5], as evidence of an ultrabasic liquid Nor does it imply that, where the marginal olivine is not skeletal, the degree of contact metamorphism should always be appreciably less

The direct experimental determination under hydrothermal conditions, by Clark and Fyfe, of the liquidus temperature of serpentinite, reinforces earlier deductions[3,6] which placed such temperatures considerably lower than had hitherto been regarded as possible An extension of this work should yield experimental results more closely applicable to the wealth of natural data now available

METALLURGY

Fatigue under Random Loads

It is often necessary to deduce the endurance of metals under a random succession of loads of varying magnitude from the behaviour of specimens tested with stress cycles of constant amplitude One way of doing this is to use the cumulative damage law, which may be written

$$N \sum_i p_i/N_i = 1 \qquad (1)$$

where N is the number of cycles of random loading required to produce fracture, p_i is the fraction of these cycles with stress amplitude s_i, and N_i is the endurance of a specimen tested at a constant stress amplitude equal to s_i

This equation can be dangerously misleading Thus Freudenthal and Heller[1] tested specimens of aluminium alloy and of steel using up to six levels of stress applied in random succession The values of p_i were adjusted to give an exponential law $p_i \sim \exp(-h\, s_i)$ like that which describes the distribution of stresses in an aircraft from atmospheric gusts Freudenthal and Heller found life-times in this test about six times shorter than those given by equation (1) They proposed a more elaborate semi-empirical formula including interaction effects between the damage produced at the different stress-levels It seemed worth while to attempt a solution of this problem on the basis of the fatigue model proposed by me in previous communications[2,3]

According to this model notches are formed in the surface of the metal by randomly distributed slip The fraction f of notches which have depths between z and $z + dz$ after t cycles is given by

$$f = F \exp(-z/\alpha t)$$

where F is a slowly varying function of z and t, and α is a constant The total number of notches with depth greater than a critical value of z, say Z, is given by integration and will be of the form

$$A \exp(-Z/\alpha t)$$

where A is another slowly varying function, and has a large numerical value Now in a test at constant stress amplitude we suppose that all notches deeper than some fixed value of Z are liable to give rise to cracks, so that the probability of crack production per cycle can be written

$$PA \exp(-Z/\alpha t)$$

where P is a constant These cracks grow rapidly and soon lead to failure so that this expression can be taken as a mortality-rate for the specimens It is very small until t becomes of the order $Z/K\alpha$, where K is $\log_e(PA)$ and is taken to be about 15

Now suppose that tests are carried out at a series of different constant stress-levels Both α and Z will depend on the value of the cyclic strain ε As in a previous communication[3] we take α to be proportional to ε, and Z to be inversely proportional to ε Thus we put $\alpha_i = a\varepsilon_i$ and $Z_i = c/\varepsilon_i$, where a and c are constants Then the life-time of the specimen in a test at constant cyclic strain ε_i is given by

$$N_i\, \varepsilon_i^2 = c/(aK) = C^2$$

in accordance with Coffin's relation between the cyclic strain and the endurance[4]

Now we consider the case of a random succession of cycles with a fraction p_i having cyclic strain ε_i The law of growth of the notches will be essentially the same as in tests at constant ε except that the constant α must be replaced by an average value $\bar{\alpha} = a\sum_i p_i\varepsilon_i$

Thus the total number of notches of depth greater than Z after t cycles will be given by

$$A \exp\left(- Z/\bar{\alpha}t\right)$$

Now consider the probability that any fatigue cycle will generate a crack This is given by the product of the fraction p_i of cycles with strain value ε_i and the number of notches with depth greater than $Z_i = c/\varepsilon_i$ Hence the mortality-rate will now be

$$AP\sum_i p_i \exp\left(- Z_i/\bar{\alpha}t\right) \qquad (2)$$

and the life-time is determined by the value of t at which this sum ceases to be very small

In order to apply this relation to Freudenthal and Heller's tests we assume the validity of Coffin's law in order to obtain values of ε_i from the life-times N_i This leads to $\bar{\alpha} = a\,C\,\sigma$, where σ is written for the sum

$$\sum_i p_i/N_i^{1/2}$$

Similarly we can write $Z_i = (c/C)\,N_i^{1/2}$ Substituting these in the exponential part of (2) gives $\exp(-KN_i^{1/2}/\sigma t)$ bearing in mind that $c/(aK) = C^2$ Now for each term of the sum in (2) there is a value of t at which this term becomes large This value of t is given by $t_i = N_i^{1/2}/\sigma\ q_i$ where I have written q_i for $1 + (1/K)\log_e p_i$

Of the various t_i values, the least, which we call t_m, is the one which determines the life-time, because the corresponding term in (2) is the first to become large Thus on this theory the growth of the notches is determined by a mean value of α in which (in any event for the distributions used by Freudenthal and Heller) the low stress values are predominant The critical depth Z on the other hand, and therefore the point at which a notch becomes a crack, is determined by one of the stress-levels, usually a high one

The details of the calculation for one of Freudenthal and Heller's runs are shown in Table 1 This is the first of their runs with aluminium alloy specimens The s_i values are given as fractions of the ultimate tensile strength, and the N_i values are taken from the smoothed curve and formulæ given by Freudenthal and Heller It will be seen that whereas the lowest value of s makes the largest contribution to σ, the largest value of s is that which gives the smallest t_i and may therefore be supposed to be responsible for the ultimate failure of the specimen The experimental value of the life-time (Freudenthal and Heller's V_r') is 3 76 × 10^6, in quite good agreement with the smallest value of t_i, namely, 4 27 × 10^6 The life-time predicted by use of equation (1) is 1 49 × 10^7, which is thus grossly over-optimistic

Table 1 CALCULATION OF LIFE-TIME
(Run 22—aluminium alloy)

s_i	$N_i^{1/2}$	P_i	P_i / $N_i^{1/2}$		q_i	t_i	
0 35	34,000	0 822	2 42	10^{-5}	0 99	390	10^6
0 45	5,750	0 1456	2 53		0 87	76	
0 55	1,150	0 02664	2 32		0 76	17 35	10^6
0 65	490	0 00458	0 94		0 64	8 78	
0 75	255	0 0010	0 39		0 54	5 41	
0 85	158	0 000182	0 11		0 426	4 27	= t_m
		σ =	8 71	10^{-5}			

Similar calculations have been carried out for the other runs on aluminium alloy specimens The results are shown in Fig 1, where the experimental life-time V_r' is plotted against the value of t_m The mean value of the ratio V_r'/t_m is 0 85 with a standard deviation of 0 15 or 18 per cent, and the straight line in Fig 1 is drawn to correspond to this ratio

The corresponding calculations for Freudenthal and Heller's runs on steel specimens are complicated by the existence of a fatigue limit These results, and the application of the theory to continuous distributions of other forms such as the Gaussian noise source used by Head and Hooke[5], will be published later

CHEMISTRY

Formation of Active Nitrogen using Sources of Alternating Current and Direct Current

ACTIVE nitrogen has been generally investigated at pressures of several tenths of an mm The majority of workers have used either a condensed or electrodeless discharge to produce the active species[1] These two methods have been favoured to such an extent that little has been done to investigate other possibilities However, work on the active gas at pressures above several mm requires more efficient methods of production

In 1932, Kaplan[2] obtained active nitrogen by using a 1 kW, 25,000 V, alternating current source and inferred that this was the first time that the after-glow was obtained by means other than a condensed discharge More recently, Stanley[3] produced the active gas with a 10,000-V alternating current supply in a capillary arc and found that the after-glow obtained at high pressures (about 500 mm) differed markedly from the usual low-pressure spectrum Berkowitz *et al*[4] used a source of alternating current to investigate the nitrogen after-glow mass-spectrometrically

In the work reported here, part of an investigation of the chemical species produced by low-temperature plasmas, active nitrogen has been produced at 50 mm by both uncondensed alternating current and low-voltage direct current sources The equipment, similar to that described by Dehmelt[5], consisted of a conventional glass vacuum system and a 25-mm internal diameter quartz discharge tube in which a 3/32 in diameter tungsten cathode and 1/8 in diameter tungsten anode were mounted with a 30-mm gap The effluent from the discharge tube was pumped down a decay tube 1 m long and fitted with quartz windows for spectrographical observation A 5-kW, 600–1,300 V alternating current and 1 kW, 0–100 V direct current source were connected in series across the electrodes The alternating current was used to initiate the plasma, which was then sustained by direct current alone operating at 50–60 V and 2–2 5 amp A 0 8-Henry choke limited the alternating current to 4 amp, the alternating current discharge was first induced with the aid of a Tesla coil Argon was used as the main plasma medium with 1–2 per cent nitrogen added through a capillary leak Commercial cylinder nitrogen (Linde) was used directly without additional purification

At pressures greater than about 1 mm, it was observed that the characteristic yellow after-glow of the first positive system of nitrogen, the $B^3\Psi$–$A^3\Pi$ interaction, was produced when either the alternating current or direct current arc was operating The identity of the after-glows thus produced was first established with a direct-vision spectroscope and then confirmed with the aid of a prism spectrograph For purposes of comparison, Fig 1 shows spectrograms of the after-glow produced by the two different sources under identical conditions of flow, pressure, etc The spectrograms were taken with a small quartz Hilger, the Kodak *I–F* plate was calibrated with mercury lines which appear as the middle spectrum in Fig 1 In the top and bottom spectra, the two features at the extreme right are the 11,7(5804 Å) and 11,8(6251 Å) bands of the first positive system of nitrogen The remainder of the bands belong to the $v' = 0$ progression of the NOβ ($\beta^2\Pi$–$X^2\Pi$) interaction No γ-bands of nitric oxide impurity are detectable in the spectrogram

Several observations can be made regarding the spectra in Fig 1 The direct current power input of approximately 150 W produces a nitrogen spectrum at least several times as intense as an alternating current input of 3,000 W Since the intensity of the after-glow is proportional to the square of the concentration of nitrogen atoms, the supply of direct current appears to be at least 50–70 per cent more effective in dissociating nitrogen than a source of alternating current twenty times as energetic This tremendous difference in efficiency was checked in subsequent experiments by titration of the two streams of nitrogen atoms with nitric oxide[6] With nitric oxide injected into the after-glow through a capillary leak, the ratio of pressures required to reach an end-point for direct- and alternating-current was 1 46 Under the conditions of these experiments, the flow-rate of nitric oxide varies at least with the square of the fore-pressure[7], so that the concentration of nitrogen atoms in the direct current after-glow was at least twice that in the alternating current after-glow. The low-pressure plasma can thus be regarded as an extremely efficient source of active nitrogen at pressures above 1 mm

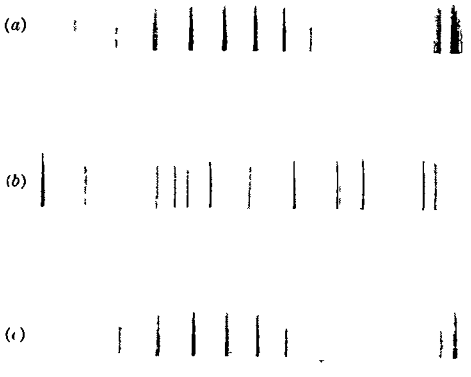

Fig 1 Spectrogram taken on a Kodak *I-F* plate with a small quartz Hilger Spectra (*a*) and (*c*) are 20-min exposures of the d c and a c after-glow, respectively The two features at the extreme right are first positive bands of nitrogen, the remaining bands belong to the NOβ system Line (*b*) is the mercury spectrum used in calibrating the plate

Microwave Spectrum of Fluoro-Acetonitrile

Fluoro-acetonitrile (FCH_2CN) is a molecule of some structural interest which is well suited to microwave study, all nuclei being well removed from the molecular centre of gravity in a structure of considerable dipole moment It should thus be possible to locate the atoms of the —CH_2CN group accurately with respect to the mass centre, by the method of isotopic replacement, and hence also to determine the position of the fluorine atom As part of such an investigation, we report an assignment of the spectrum of the principal isotopic form Transitions of the *R*-branch corresponding to the *A*-component of the molecular dipole have been identified for $J = 0 \rightarrow 1$, $1 \rightarrow 2$, $2 \rightarrow 3$ and $3 \rightarrow 4$, between 9 and 38 Gc/s, *Q*-branch lines for the same component, $J_{1,J} \rightarrow J_{1,(J-1)}$, have been assigned for $J = 6$, 9, 10, 11 and 12 Corresponding to the *B*-component of the dipole, lines of the type $J_{0,J} \rightarrow J_{1,(J-1)}$ have been measured for *J* values of 1–5

Analysis leads to the following rotational and centrifugal distortion constants, in Mc/s

$$A = 36{,}577\ 47 \pm 0\ 10 \qquad D_J = 0\ 0033 \pm 0\ 0007$$
$$B = 4{,}781\ 29 \pm 0\ 02 \qquad D_{JK} = -0\ 068 \pm 0\ 003$$
$$C = 4{,}339\ 75 \pm 0\ 02 \qquad \delta_J = 0\ 00056 \pm 0\ 00001$$

Nuclear quadrupole splittings due to nitrogen-14 are resolvable, and of approximately the anticipated magnitude They are at present being more accurately measured, as are Stark effect displacements for evaluation of the dipole moment components

Intensities of the lines should permit examination of further isotopic forms, and work on this is continuing in order to allow completion of the structure determination It may be noted, however, that, if the —CH$_2$CN group were assigned a structure close to that in methyl cyanide[1], the constants so far measured would require a carbon–fluorine distance of about 1 38 Å, and an angle FCC near 111° The present results are thus compatible with a carbon–fluorine distance similar to that in methyl fluoride[2], and a carbon–carbon distance similar to that in methyl cyanide Definite conclusions, however, must await further measurements

Rubeanic Acid as Stabilizer of Aqueous Solutions of Ascorbic Acid

Especially noteworthy among the stabilizers of ascorbic acid solutions are sulphydric organic derivatives such as glutathione, thiourea, methylthiouracyl, cysteine[1–3], 2-carbethoxy-mercapto-1-methylglyoxaline[2,3], dithioglycerin, thioglycolic acid[2], etc On the other hand acids have found application as agents reducing the rate of oxidation of ascorbic acid in solutions Among these oxalic acid plays an important part In 2 per cent and 1 per cent dilutions it is applied as a stabilizer of synthetic ascorbic acid in various solutions and of ascorbic acid in biological material

This suggested the use of rubeanic acid for preventing oxidation of ascorbic acid in aqueous solution Rubeanic acid is a diamide of thio-oxalic acid We wanted to investigate the stability of 0 01 per cent aqueous solution of ascorbic acid in the presence of rubeanic acid

Ascorbic acid solutions containing rubeanic acid were prepared, and the ascorbic acid content was assessed during storage Moreover, the same solutions were subjected to the effect of oxidizing factors, such as irradiation with a quartz lamp or introduction of cupric ions, the ascorbic acid content being measured all the time This was carried out by means of Tillmann's method, consisting in the reduction of 2,6-dichlorphenolindophenol Table 1 shows results obtained in determining the stability of ascorbic in rubeanic acid solutions

Table 1 Stability of 0 01 per cent Aqueous Solution of Ascorbic Acid in the Presence of Rubeanic Acid

Time of storage (hr)	Ascorbic acid content (per cent of initial content) in aqueous solution	in 0 01 per cent rubeanic acid	in 0 001 per cent rubeanic acid
—	100 0	100 0	100 0
0 5	82 0	99 2	98 3
1 0	49 9	98 3	97 6
2 0	33 3	98 3	96 0
3 0	16 6	97 6	96 0
4 0	13 3	97 6	94 4
23 0	0 0	92 8	80 0

In Table 2 are assembled the results obtained in assessing the stability of ascorbic acid solutions irradiated with a quartz lamp

Table 2 Stability of 0 01 per cent Aqueous Solution of Ascorbic Acid in the Presence of Rubeanic Acid on Irradiation with a Quartz Lamp

Time of storage (hr)	Ascorbic acid content (percentage of initial content) in aqueous solution	in 0 01 per cent rubeanic acid
—	100 0	100 0
0 5	69 7	98 3
1 0	51 3	98 3
2 0	21 0	98 3
3 0	9 1	97 6
4 0	3 3	97 6

Table 3 shows the ascorbic acid content in 0 01 per cent and 0 001 per cent solutions of rubeanic acid in the presence of copper ions (0 001 per cent and 0 0001 per cent copper sulphate)

Table 3 Stability of Ascorbic Acid in 0 01 per cent Solution, in the Presence of Rubeanic Acid and on Admixture of Copper Ions

Time of storage (hr)	Ascorbic acid content (percentage of initial content)				
	in 0 001 per cent CuSO$_4$	in 0 01 per cent rubeanic acid		in 0 001 per cent rubeanic acid	
		in 0 001 per cent CuSO$_4$	in 0 0001 per cent CuSO$_4$	in 0 001 per cent CuSO$_4$	in 0 0001 per cent CuSO$_4$
—	100 0	100 0	100 0	100 0	100 0
0 5	10 0	99 0	99 3	98 3	100 0
1 0	0 0	99 0	99 3	97 4	99 2
2 0	—	98 1	98 4	91 2	98 3
3 0	—	95 8	96 5	91 2	96 6
4 0	—	93 4	95 9	91 2	95 8
24 0	—	80 0	86 3		
48 0	—			66 9	72 3

From the results in Tables 1–3 rubeanic acid is seen to be a stabilizer of ascorbic acid The stability of the solutions is dependent on the amount of rubeanic acid added. Ultra-violet radiation and copper ions in solution, which are factors accelerating the oxidation of ascorbic acid, lose their activity in the presence of rubeanic acid

Ligand Field for Chromic Ions in the Corundum Lattice

Recent work on absorption spectra and lattice spacings in the Al$_2$O$_3$–Cr$_2$O$_3$ solid solution[1–6] has been in sufficient agreement to warrant a fitting of the optical results to the crystal field-splitting diagram[7]. The relevant terms are shown in Fig 1, which also shows the transitions involved in the yellow and blue absorption bands

Assuming the Racah parameter B to be constant throughout the system, it is impossible to obtain a fit no matter what value of B is chosen An example is shown in Fig 2, with B = 650 cm^{-1} This value was chosen to give a fit at about 5 5 per cent Cr$_2$O$_3$, where the observed maxima for ruby (Graham[1]) and Cr(H$_2$O)$_6^{3+}$ (Tsuchida[8]) are identical.

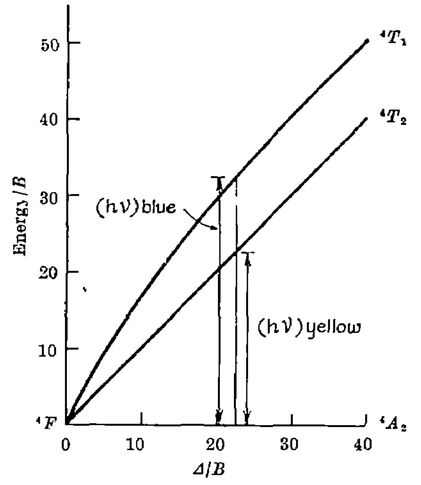

Fig 1 Energy-level diagram for the splitting of ^4F in an octahedral field

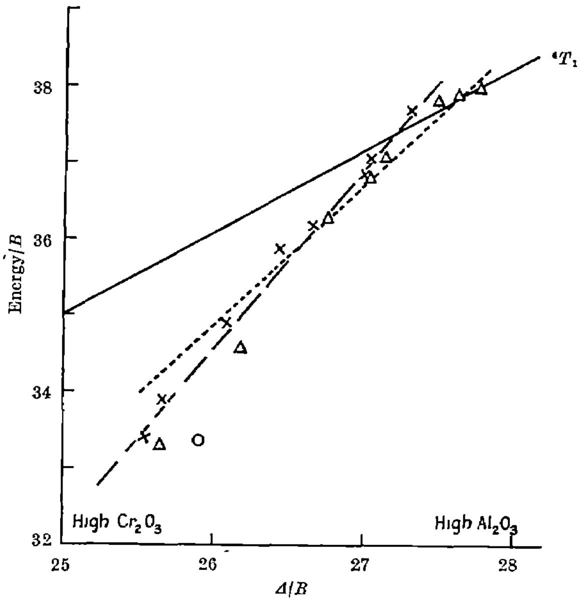

Fig 2 Experimental energy values derived for B = 650 cm^{-1} O, Graham, Δ, Schilly, ×, Schmitz-Dumont and Reinen, — —, Schultz

It is known that an increase in covalent bonding[9] and/or charge transfer[10] results in a decrease in B There is evidence[1] for the existence of bonding other than ionic in both Al_2O_3 and Cr_2O_3, and it can be shown that the proportion of such bonds increases as the chromium content decreases This follows from a consideration of cell volumes Thus if we assume ionic bonding and regular octahedral surroundings for the Al^{3+} and Cr^{3+} ions in pure Al_2O_3 and Cr_2O_3 respectively, we would expect an increase in unit cell volume of 10 35 per cent in passing from Al_2O_3 to Cr_2O_3, whereas the observed increase is 13 5 per cent The contents of the unit cell (on the basis of ionic volumes) have increased in volume by only 2 8 per cent, so that in the absence of other types of bonding one would expect distortions of the octahedron to accommodate a good deal of the increase calculated here The observed increase in cell volume is therefore much greater than that to be expected unless Al_2O_3 is more covalent in character than Cr_2O_3 The lattice spacings[1,2] tend to confirm this conclusion, as the effective radius of the chromium ion is greater at the alumina-rich end of the solid solution, perhaps indicating a greater amount of charge transfer Based on present ideas, it would be expected that B would increase as the chromium content increases

However, if we calculate the values of B required to fit the experimental and theoretical curves at all points, we find that B increases approximately linearly with decreasing Cr_2O_3 content or increasing Δ (Fig 3) Although there is some scatter between observers, the result is quite clear, and the variation of B is very large The results of Graham and of Schultz are closely linear, and the lines of best fit have been plotted in Figs 1–3 The accurate single crystal absorption data of Mandarino[4] on weighting the ordinary and extraordinary components in the ratio 2 3 according to the experimental result of Schultz[11] give a value of Δ 18 11 cm^{-1} for Al_2O_3 in excellent agreement with ref 1

The increase in Δ as the chromic oxide content decreases is easily explained on the basis of decreasing metal-ligand spacing, but the corresponding increase of B is anomalous Since the axial ratio is almost constant throughout the system, the trigonal component of the field is unlikely to account for the anomaly

Goodenough[12] points out that interactions between the ligands and the d-shell of the metal in the corundum structure are weak if there are three electrons or less in the d-shell, and postulates direct cation–cation coupling as the cause of antiferromagnetic ordering in these structures Chromic oxide itself is antiferromagnetic with a Néel temperature near room temperature, and it would appear that the overlap of the d-orbitals of adjacent Cr^{3+} ions which results in the antiferromagnetic ordering may also explain the absorption spectrum if the d-shells interact to some extent even in the dilute solutions[13] The decrease in B would then correspond to increasing cation–cation interaction as the chromium content increased This is again consistent with the structural results[1], as the metal-to-metal distance in Cr_2O_3, 2 58 Å , is significantly less than that in Al_2O_3, 2 73 Å In terms of the cation radius, the difference is even more marked

It is felt that the anomalous values of B and Δ obtained by one of us (J G) for pure Cr_2O_3 (the separate points shown in Figs 2 and 3) are associated with

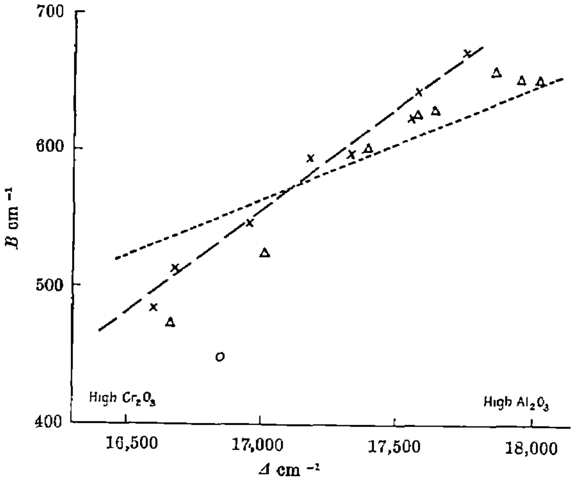

Fig 3 Variation of B with crystal field (details as for Fig 2)

antiferromagnetic ordering in this sample This would be expected to result in a discontinuous decrease in B, but the accompanying increase in Δ is not so easy to understand

BIOCHEMISTRY

Biosynthesis of L-Ascorbic Acid : Missing Steps in Animals incapable of synthesizing the Vitamin

It has been reported[1] that cyanide greatly stimulates the synthesis of L-ascorbic acid from D-glucuronolactone by the liver microsomes of the rat By this method using cyanide it was found that either the liver or the kidney tissue of all the species examined which are known to be independent of an exogenous source of ascorbic acid was able to synthesize L-ascorbic acid, while the corresponding tissue of those which are dependent on such a source could not Whether the enzyme system concerned was present in the liver or the kidney tissue depended on the position of the species in the phylogenetic scale of evolution[2] This technique revealed further that, apart from man, monkey and the guinea pig, the India fruit bat (*Pteropus medius*) and the red-vented bulbul (*Pycnonotus cafer*) were unable to synthesize L-ascorbic acid, and this was confirmed by the production of experimental scurvy in the bulbul and its cure by the administration of L-ascorbic acid[3] This communication concerns the location of the genetic defect in all these species, which distinguishes them from those which can synthesize L-ascorbic acid

According to a scheme given elsewhere[4] indicating the probable biosynthetic pathway of ascorbic acid in those species which can make it, the following representation (Fig 1) may be made in regard to the substrates and the enzymes of the microsomes and of the soluble supernatant involved in this synthesis

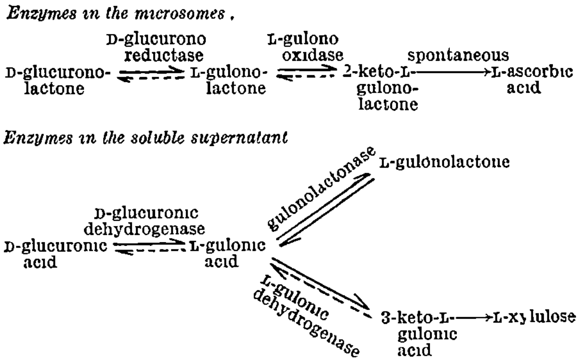

Fig 1 Schematic representation showing the substrates and the enzymes of the microsomes and of the soluble supernatant involved in the biosynthesis of L-ascorbic acid in animal tissue

Fig 1 indicates that with D-glucuronolactone as substrate, microsomal enzymes alone can convert it into L-ascorbic acid through L-gulonolactone and 2-keto-L-gulonolactone With D-glucuronic acid as substrate, however, the microsomes require the addition of the soluble supernatant which supplies the necessary enzymes to convert D-glucuronic acid into L-gulonolactone, which can be then converted into L-ascorbic acid by the microsomes We have previously reported[4] that the failure of the guinea pig to synthesize L-ascorbic acid was due to the absence of L-gulono oxidase, which oxidizes L-gulonolactone to 2-keto-L-gulonolactone Using the tracer technique this was also observed by Burns *et al* [5] and by Burns[6] in regard to man, monkey and the guinea pig

It has now been found, however, that not only L-gulono oxidase but also the other microsomal enzyme, D-glucurono reductase, which converts D-glucuronolactone into L-gulonolactone, is specifically absent from those species which cannot synthesize L-ascorbic acid This has been demonstrated by the fact that, under anaerobic conditions, incubation of D-glucuronolactone with liver or kidney microsomes from man, monkey, the bat, the guinea pig and the bulbul in the presence of cyanide did not result in the formation of L-gulonolactone whereas in similar experiments with microsomes from rat and goat livers, L-gulonolactone was produced as an intermediate L-gulonolactone was identified by paper chromatography of the deproteinized and concentrated incubated mixture using (*a*) ethyl acetate/acetic acid/water (3 1 3, v/v, upper phase, descending), (*b*) ethanol/acetic acid/water (8 1 1 v/v, descending), (*c*) acetone water (4 1 v/v, ascending) as the irrigating solvents The R_F values for D-glucuronolactone and L-gulonolactone were (*a*) 0 51 and 0 43, (*b*) 0 62 and 0 54, (*c*) 0 72 and 0 55 respectively The lactones were identified on the chromatogram by the hydroxamic acid method[4] L-gulonolactone has also been identified by Suzuki *et al* [7] as a product of anaerobic incubation of D-glucuronolactone with rat-liver microsomes in the presence of cyanide

The absence of D-glucurono reductase was further revealed in the following way The microsomes of the liver or kidney tissue (40 mgm protein) from all the aforesaid species which cannot synthesize L-ascorbic acid were incubated with D-glucuronolactone (20 μmoles) in the presence of sodium phosphate buffer (0 02 M, pH 7 0) and potassium cyanide (0 05 M) After incubation, the mixture was deproteinized with perchloric acid, neutralized with caustic potash and, after filtering off potassium perchlorate, freed from cyanide by acidification with N hydrochloric acid followed by evaporation to dryness under suction The residue was taken up in a minimum volume of water, neutralized and then incubated with goat liver microsomes, but no L-ascorbic acid was formed Had there been any formation of L-gulonolactone, it would have led to the synthesis of L-ascorbic acid in the absence of cyanide on addition of goat liver microsomes[4] A control experiment starting with L-gulonolactone (5 μmoles) instead of D-glucuronolactone resulted in the formation of L-ascorbic acid (0·5 μmole) indicating little destruction of L-gulonolactone in the process of removal of cyanide.

In the scheme given (Fig. 1), the supernatant enzymes, converting D-glucuronic acid into L-xylulose and into L-gulonolactone, have been found to be present in all the above-mentioned species requiring dietary ascorbic acid[8]. Thus there are two genetic blocks in regard to the synthesis of L-ascorbic acid in these species: (1) the absence of D-glucurono reductase so that D-glucuronolactone cannot be reduced to the intermediate L-gulonolactone, (2) the absence of L-gulono oxidase so that L-gulonolactone cannot be oxidized to the intermediate 2-keto-L-gulonolactone, even if the enzymes of the soluble supernatant bring about the conversion of D-glucuronic acid into L-gulonolactone. That these two enzymes are actually present but are masked by some microsomal inhibitory substance is considered unlikely, as the addition of the microsomes from these species to the solubilized enzyme from rat liver, prepared as described before[4], was not found to inhibit the synthesis of L-ascorbic acid by the latter.

Our thanks are due to the Indian Council of Medical Research for financing this work.

Riboflavin and Liver Sulphydryl-Levels in Mice

DURING the course of a series of investigations of the sulphydryl content of mouse liver under varying experimental conditions, it was found that during a period of nine months there was a steady increase in the level found in control animals. The liver —SH content rose from 31·4 ± 1·7 μgm per 100 mgm wet weight to 34·3 ± 5·9 μgm per 100 mgm wet weight. In all cases the groups of animals used comprised a minimum of 10 Strong *A* male mice. This steady increase in control-levels was succeeded by a sharp fall to 27·7 ± 2·6 μgm per 100 mgm wet weight in a group of similar animals. Consideration of factors which might have been involved in this variation led to suspicion of the diet, particularly since, during the period in question, growth-rates in these animals had shown deviations from the expected pattern. Further examination of the diet question focused suspicion on the vitamin content, and especially on the constancy of the riboflavin-level. We were thus led into an investigation of the influence of dietary riboflavin on liver —SH levels.

All measurements of —SH levels recorded in the following paragraphs have been made by the method described by Calcutt and Doxey[1]. Whereas in the original use of this technique millivoltmeters were used for the potentiometric titrations these have now been replaced by transistorized titrimeters based on Stock's design[2]. These instruments have proved superior to millivoltmeters in operation as the settling time is negligible and scale movements are large and easily read.

All experimental work has been carried out with Strong *A* mice. These have been used in batches of the same age and, so far as possible, of approximately equal weights. This latter precaution has been taken in view of Calcutt's[3] finding of an inverse relationship between body weight and —SH content per unit mass of liver. The effects of addition and withdrawal of riboflavin from the diet have been examined and also the effects of riboflavin given by injection.

Addition of riboflavin to drinking water. Twenty mice were divided into two groups of ten each. While both groups were maintained on a normal pellet diet, one group received fresh water to drink whereas the second was given a saturated solution of riboflavin in tap-water. After four days the liver —SH content was estimated for all the animals. The group which had been given water had an —SH level of 33·9 ± 2·8 μgm per 100 mgm of wet weight of liver, while the corresponding figures for the group given riboflavin were 33·5 ± 2·6 μgm of —SH per 100 mgm of wet weight of liver. There is obviously no significant difference between the two groups. Since the solubility of riboflavin is only 0·01 per cent in water, the intake by the mice from this source would be small. Further, the actual absorption may have been even smaller, as mice eat and drink at separate times, and the evidence collected by Bro Rasmussen[4] indicates a requirement for the presence of protein for the adequate absorption of riboflavin. The slightly bitter taste of the solution may also have limited drinking by the mice in question. In the circumstances, the results obtained in this experiment are not surprising.

Withdrawal of riboflavin from the diet. Thirty male mice were placed on a synthetic diet obtained as a vitamin-free diet from British Drug Houses, Ltd., of London. To this, vitamins were added in the amounts used by Greenstein, Otey, Birnbaum and Winitz[5] in their experiments on synthetic diets. After 28 days, during which period the animals maintained their weight and health, ten were taken as controls and the liver —SH content was estimated. The remaining animals were transferred to the vitamin-free diet supplemented, as previously, with all vitamins except riboflavin. These animals were killed in batches of five at intervals for liver —SH measurements. The results are shown in Fig. 1, where it will be seen that the liver —SH content rose above the control-level seven days after withdrawal of the riboflavin.

Effects of riboflavin by injection. Thirty male mice were divided into two batches of 15 each. One lot received an intraperitoneal injection of 0·1 mgm of riboflavin in 1 ml. of distilled water each mouse. Liver —SH content was estimated on all animals, those that had received riboflavin being killed 1 hr. after the injection. The control animals had 34·5 ± 4·2 μgm of —SH per 100 mgm of wet weight of liver whereas the corresponding figure for the riboflavin-treated animals was 28·8 ± 4·75 μgm of —SH. In a similar series, using female mice, the treated animals were killed 18 hr. after the injection. This time the control —SH level was 38·6 ± 3·8 μgm per 100 mgm wet weight of liver and the level in the treated animals was 25·3 ± 5·0 μgm per 100 mgm wet weight of liver. As a further experiment a batch of male mice was injected, as previously, with an

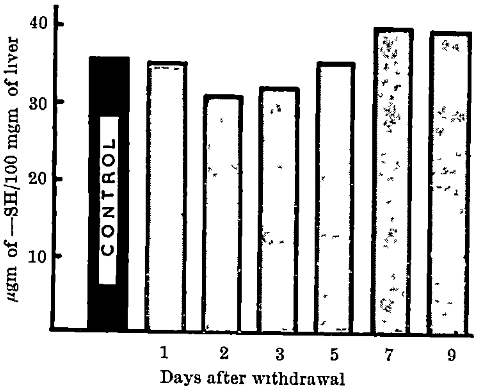

Fig 1 Effects of withdrawal of riboflavin from mouse diet on liver —SH levels

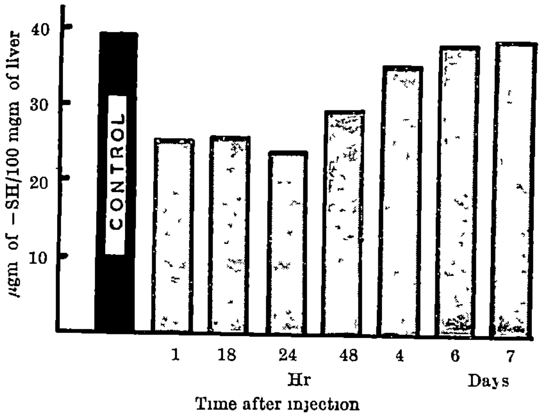

Fig 2 Effects of injected riboflavin on mouse liver —SH levels

aqueous solution of riboflavin These were killed in batches at daily intervals and the liver —SH level estimated Return to the control-level did not take place until six days after treatment

Tissue riboflavin-levels have often been associated with tissue protein content As a follow-up to the above experiments, which were performed on mice fed a high-quality diet, the effects of riboflavin on animals on an inferior diet have been examined Mice were fed rice and water only for ten days and then received an injection of 0 1 mgm of riboflavin in 1 0 ml of distilled water Estimates of liver —SH level showed that this remained depressed until six days after treatment, as in the previous experiment The results are shown in Fig 2

It is known that riboflavin plays a part in oxidation/reduction systems as a consequence of its participation in various enzyme systems The experimental results reported here now indicate that riboflavin may exercise a function in relation to the general oxidation/reduction status of the liver cell This activity would appear to be independent of the nutritional state of the animal, since there is no apparent distinction between the effect of injected riboflavin in well-fed or poorly fed animals From this it seems unlikely that the effect involves the riboflavin in conjunction with the proteins of the cell

The actual mechanism of the effect is at present unknown Iwaki[6] has shown that a direct combination of glutathione and riboflavin can occur, but even if this did happen the linkage would probably be broken by the more reactive mercurial used in the —SH estimation Riboflavin can act as an electron acceptor, and it is possible that, rather than any direct chemical combination of the vitamin with cellular components, we have an induced oxidation of various cellular components which, in turn, are responsible for maintenance of sulphur-containing groups in the reduced form It has in fact been suggested by Booth and Boyland[7] that riboflavin inhibits the microsomal hydroxylating system by causing the oxidation of reduced triphosphopyridine nucleotide, which is required for maintenance of —SH in the system

Recently, Hsu and Chow[8] have found that thiamine deficiency in rats leads to an elevation in the level of liver glutathione This finding, in conjunction with the results recorded above, suggests that dietary vitamin-levels, at least of thiamine and riboflavin, may take a major role in determining the biochemical status of the liver Further, it once more stresses the extreme importance of strict dietary control of animals used for biochemical work

In vivo and *in vitro* Inhibition of Aromatic Hydroxylation by Riboflavin

Detailed and extensive investigations of the metabolism of polycyclic hydrocarbons have been carried out over many years, but it is only recently that information linking the metabolism of these agents with an enzymic system present in liver has become available It has been found that hydroxylation of the carcinogenic 3 4 benzpyrene[1] and the non-carcinogenic naphthalene[2] is brought about by an enzyme, or 'hydroxylase'[1], which occurs in the microsomal fraction of liver homogenates, this system requiring reduced triphosphopyridine nucleotide and molecular oxygen for activity One of us (K H H) has found that the same or a similar system is also active against pyrene and 1 2 benzanthracene The products obtained are similar to those obtained during *in vivo* metabolism This work will be reported in detail elsewhere

This hydroxylating system is susceptible to sulphydryl complexing agents, such as *p*-chloromercuribenzoic acid The information concerning the effects of riboflavin on liver sulphydryl-levels reported by Calcutt, Doxey and Coates (see previous communication) led us to further consideration of the effect of riboflavin on microsomal hydroxylation Previously, it had been found by Booth and Boyland[2] that flavine mononucleotide (FMN) is an effective inhibitor of the microsomal hydroxylation of naphthalene It seemed desirable, therefore, to see whether riboflavin also affected hydroxylation of other compounds

The pyrene hydroxylating system (active in the conversion of pyrene to 3-hydroxypyrene) was chosen for the first investigation The low solubility

Table 1 INHIBITION OF PYRENE HYDROXYLATION BY RIBOFLAVIN

Compound	Concentration	Percentage inhibition
'Beflavit'	10^{-3}	100
	10^{-4}	95
'Dummy' 'Beflavit'	10^{-3}	70
	10^{-4}	15
FMN	10^{-3}	60
	10^{-4}	20

of riboflavin in aqueous solutions led us to the use of a concentrated (5 mgm./ml.) commercial preparation made in a solvent base. This was 'Beflavit', prepared by Roche Products, Ltd., England. For control purposes the solvent base preparation was also used. The results, together with those obtained using FMN, are summarized in Table 1.

It is evident from these figures that the solvent base itself contributes to the inhibitory powers of 'Beflavit', but even when allowance is made for this, riboflavin itself appears appreciably more active than the FMN.

Identical findings were then obtained in a similar series of experiments based on the metabolism of 3 : 4 benzpyrene.

The effect of riboflavin on the hydroxylation of 3 : 4 benzpyrene *in vivo* was then examined. Ten mice were each given an intraperitoneal injection of 0.1 mgm. of riboflavin in water and, 1 hr. later, an intravenous injection of 0.6 mgm. of benzpyrene as a colloid in 1 ml. of water. A second group of ten mice each received a similar benzpyrene injection. This group acted as controls. The excretion of phenolic metabolites, predominantly 8-hydroxybenzpyrene, in the fæces was then followed over a period of 48 hr. The animals treated with the hydrocarbon alone excreted approximately 25 per cent of the total injected dose as phenolic derivatives during this period. The difference between this group and that which had received prior treatment with riboflavin was striking, for this group excreted less than 1 per cent of the dose as metabolites during the same period. The benzpyrene in this group was not excreted unchanged, since only trace amounts were detected in the urine and fæces. Whether it is stored or metabolized in a different manner is still to be determined.

This last experiment provides excellent confirmation of the *in vitro* experiments and also supports the view that the microsomal hydroxylating system observed *in vitro* is a true representation or model of the normal cellular process. Further, this last experiment is interesting in that this is the first time that it has been shown that the metabolism of benzpyrene may be influenced by dietary or other external agents.

It is not yet clear which part of the hydroxylating system is inhibited by riboflavin. It appears unlikely that riboflavin becomes bound to the enzyme system, since microsomes prepared from animals pretreated with riboflavin show undiminished activity as compared with control preparations, provided that they are washed several times with 1.15 per cent potassium chloride solution. This would suggest that the effect is on the coenzyme moiety rather than the enzyme itself.

Apart from the more obvious implications arising from this work in respect of the nutritional state of animals used in metabolic studies, there is the question of riboflavin and carcinogenesis by polycyclic hydrocarbons. Boyland[3] has given reasons for considering that carcinogenesis by polycyclic hydrocarbons is associated with the metabolism of these compounds. If this is true, then the influence of riboflavin on the metabolism of these agents should be reflected in the carcinogenic activity. Further evidence of possible effects of riboflavin in carcinogenesis is given in the finding that the hepatocarcinogen (4′ dimethylaminoazobenzene) is metabolized by the same, or a similar, microsomal enzymic system[4], whereas the carcinogenic action of this agent is inhibited by a high dietary riboflavin intake[5]. Further consideration of these problems will be given elsewhere.

We are grateful to Roche Products, Ltd., Welwyn Garden City, England, for the gift of samples of the solvent base in which 'Beflavit' is prepared.

Effect of Insulin on the Phosphorus-32 Mononucleotide Labelling of the Isolated Rat Diaphragm in the Controlled Absence of Extracellular Glucose

EXTENSIVE work on glucose transport into the cell under the influence of insulin and on the metabolic consequences of this transport has been carried out on the eviscerated animal[1], the isolated rat diaphragm[2], the isolated perfused heart[3] and the isolated epididymal fat pad[4,5]. Insulin stimulation seems to involve not only an enhanced transport-rate, but also an increased intracellular distribution space as measured with non-metabolizable sugars[2] and amino-acids[6,7]. However, some recent reports[8,9] dealing primarily with incorporation of carbon-14 into proteins of rat diaphragm, in the absence of added glucose, demonstrated a striking insulin effect, which could not be explained by an increased accumulation of amino-acid precursors of the labelled protein. This effect may be correlated[10] with another report mentioning the action of insulin on endoplasmic reticulum proliferation in the fat pad[11]. Whatever the mechanism of action of insulin may be, stimulation of glucose transport, protein synthesis or any other metabolic event is bound to be reflected in the turnover of free mononucleotides and especially adenosine nucleotides, the role of which is essential in the activation of sugars, fatty acids[12] and amino-acids[13].

The present communication reports an effect of insulin on the labelling of free mononucleotides in the isolated rat diaphragm in the controlled absence of extracellular glucose. The isolated rat diaphragms were first washed, for 5 min., in Krebs–Ringer bicarbonate medium[14] at 37°, in an atmosphere of 95 per cent oxygen plus 5 per cent carbon dioxide. After removal and careful blotting of the diaphragms, they were incubated in fresh Krebs–Ringer bicarbonate medium with or without added glucose and insulin

~ = labile phosphate bonds

The washing and incubation were performed in a Warburg apparatus After 5 min gassing and 10 min pre-incubation, a known amount of phosphorus-32 was tipped in the incubation medium and the incubation continued for another 10 min The amount of glucose still present in the diaphragm at the moment the phosphorus-32 was added to the medium can be demonstrated (Fig 1) This amount has been determined by a chromatographic procedure After rapid weighing, the diaphragms were homogenized in ice-cold 10 per cent trichloracetic acid, the extract centrifuged, an aliquot taken for the estimation of inorganic phosphate and phosphocreatine and specific activities The remaining supernatant was processed using a chromatographic procedure, essentially identical to that described in a previous report[15] adenosine triphosphate (ATP), adenosine diphosphate(ADP), adenosine monophosphate (AMP), diphosphopyridine nucleotide (DPN), and the sum of uridine and guanosine phosphates (U + G) were thus separated, their amounts and their specific activities measured The 'residual phosphate' comprising mainly the phosphorylated intermediates of glycolysis has also been determined In all cases, the total phosphorus and radioactivity recovered after the fractionation procedure amounted to 90 per cent–100 per cent of the original phosphorus and radioactivity present in the trichloracetic acid extract It should be mentioned that the amount and specific radioactivity of intracellular inorganic phosphate has been calculated from the total inorganic phosphate and the extracellular phosphate present in the incubation medium assuming an extracellular space of 22 per cent as measured by Kipnis and Cori on the cut diaphragm[2]

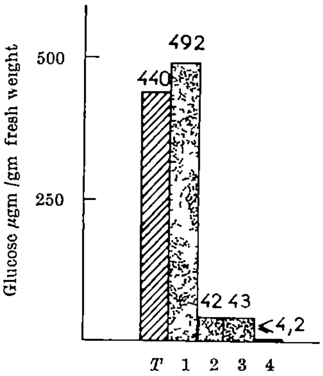

Fig 1 Glucose content of rat diaphragm incubated under various conditions *T*, Theoretical value for (1) (extracell space, 22 per cent), 1, washed 5 min , 37°, Krebs–Ringer glucose, 2 mgm /ml , 2, washed 5 min , 37°, no glucose, 3, washed 5 min , 37°, no glucose, insulin, 10 µgm /ml , 4, same as 3 plus incubation fresh medium 15 min

Table 1 shows a characteristic result obtained with normal rat diaphragms in absence or in presence of added insulin (10 µgm /ml) or glucose (2 mgm / ml)

From these results the following conclusions may be drawn (1) There seems to be no influence of insulin or glucose on the amount of the different phosphate fractions in the rat diaphragm except so far as the 'residual phosphate' is concerned The amount of this phosphate fraction increases in the presence of glucose and still more with glucose + insulin, as may be expected if it consists mainly of glycolytic intermediates (2) There is no influence of insulin or glucose on the rate of penetration of radioactive phosphorus into the diaphragm of the normal rat, as visualized by the ratio of the specific activities, namely, intracellular phosphate/extracellular phosphate (3) There is a striking enhancement of the labelling of phosphocreatine, ATP, ADP, uridine and guanosine phosphates by insulin in the presence or absence of added glucose The increase of specific activity of these fractions with respect to intracellular phosphates averages 50 per cent for phosphocreatine (PC), 80 per cent for ATP, and 100 per cent for ADP No significant labelling of ribose-linked phosphoryl groups such as AMP or DPN occurred within our limited times of incubation (4) In the presence of glucose there is a definite rise of the labelling of ATP both with or without insulin There is a slight glucose effect on the specific activities of phosphocreatine and the 'residual fraction' and a marked effect on the labelling of the uridine and guanosine phosphates But there is no influence whatsoever of glucose on labelling of ADP, whereas insulin exerts its most striking effect on the labelling of this substance

It is thus clear that insulin has a marked effect on the labelling of phosphorylated coenzymes even in the absence of any measurable amounts of glucose within or without the cell The exceedingly small amount of glucose found in the diaphragm with the conditions under which the present experiments were carried out could as well have arisen from the limited breakdown of labile esters like glucose-1-phosphate or of glycogen itself The marked effect of insulin on the labelling of the terminal phosphate group of ADP, which seems to be in equilibrium with the second phosphorylated group of ATP, is what one might expect to occur if amino-acid activation including a 'pyrophosphate split' of ATP (ref 13) and subsequent re-phosphorylation of AMP by an adenylate kinase system would occur However, many other metabolic events such as, for example, activation of fatty acids[12] and increased dephosphorylation of ADP by myokinase could equally well explain the increased formation of AMP

Finally, it must be borne in mind that although insulin does not appear to increase the penetration of radioactive phosphate into the cell of the diaphragm, a mechanism whereby insulin could promote penetration of phosphate into a restricted compartment of the muscle cell where re-phosphorylation of AMP to ADP and ATP normally occurs, thus increasing the actual labelling of the two terminal phosphorylated groups of ATP, cannot be excluded at present

Effects of the Sulphur Amino-Acids on the Vitamin A Content in Liver of Rats

RECENTLY we reported[1] the effect of vitamin A on the cystine content in the skin of rats and suggested a causative relationship between vitamin A and sulphur amino-acids The present work was designed to investigate the effects of dietary supplementation of sulphur amino-acids on the vitamin A content in liver of rats

The test animals used were rats of both sexes of the Wistar strain weighing about 40 gm They were housed in individual compartments with screen bottoms and fed the basal diet deficient in sulphur amino-acid content as shown in Table 1

Table 1 COMPOSITION OF THE BASAL RATION

	Exp 1	Exp 2
Milled rice	60 gm	92 gm
De-fatted sovbean meal	26 ,,	6 ,,
Soybean oil	5 ,,	2 ,,
Dried yeast	5 ,,	0 ,,
Sodium chloride	0 ,,	1 ,,
Calcium carbonate	0 ,,	1 ,,
Salt mixture (Hegsted)	4 ,,	0 ,,
Supplements per rat daily		
Thiamine	0 μgm	20 μgm
Riboflavin	0 ,,	50 ,,
Vitamin A palmitate	100 ,,	1 ,,
α-Tocopherol	300 ,,	0 ,,

In the first experiment we investigated the effect of supplementary methionine, cystine, lysine and gelatin on the basal diet Five groups of rats were given different diets as described in Table 2 Rats in group 1 were fed the basal diet and used as control Groups 2, 3, 4 and 5 were given methionine, cystine, lysine and gelatin respectively. The amount of gelatin was so adjusted that the lysine content in it was equal to the amount of lysine used in group 4 During the four-week feeding period, the amount of diet was restricted to 6 gm per rat daily during the first week, and thereafter increased by 1 gm a week At the end of four weeks the animals were killed Pieces of liver from the median and left lateral lobes were removed immediately, weighed and saponified with alcoholic potassium hydroxide, and the amount of vitamin A extracted by di-ethyl ether was measured by the $\alpha\alpha'$-glycerol dichlorohydrin method[2] For determination of the sulphydryl activity of the liver, another weighed piece was homogenized and incubated with monoiodoacetic acid at 37° C for 1 hr and the liberated iodine in its deproteinized filtrate was measured by Mori's method[3] The absorption coefficient (E) obtained on a colorimeter was taken as the measure of sulphydryl activity

The result of the first experiment showed that the vitamin A content in liver of animals fed the methionine-supplemented diets, but not those given the lysine- or gelatin-supplemented diets, was strikingly elevated above that of the control Cystine supplementation showed a moderate increase in vitamin A content of liver over that of the control animals The sulphydryl activity showed close parallelism with vitamin A content, the highest value was obtained with a supplement of methionine, the next highest being that of cystine

In the second experiment we investigated the effect of methionine on the vitamin A content in liver of rats fed an inadequate supply of protein and vitamin A In this case, a basal diet of lower protein content than that in the first experiment was used and was given in conjunction with the liberal or small dosage of vitamin A, the small dosage being inadequate to allow accumulation of the vitamin in the liver Amount of supplement of the four groups and analytical data are shown in Table 3

The results of the second experiment showed that with the addition of methionine to the diet of low protein content, the differences in the content of vitamin A in livers were less pronounced but still significant, in other words, the vitamin content was higher than those of the unsupplemented regardless of the presence of an ample or minimum supply of vitamin A

Present findings indicate that the dietary supplement of sulphur amino-acids, especially methionine, elevated the vitamin content in the liver of rats, while lysine or gelatin increased it a little or not at all above that of rats fed the basal diet The basal and supplemented groups of rats were normal in general appearance and no apparent difference was observed between their growth-rates It is remarkable that the sulphur amino-acids alone had an increasing effect on the vitamin A content in liver This is in agreement with our suggestion[1] that vitamin A is involved in the metabolism of sulphur amino-acid

Concurrent with the increase of vitamin A content in liver, the sulphydryl activity in liver and muscle of rats fed a diet supplemented with methionine increased In this connexion, Flesch *et al* [4] noticed that vitamin A was able to unite with the sulphydryl

Conservation of the Biological Activity of a Soluble Ribonucleic Acid

PREVIOUS investigations[1] carried out in one of our laboratories have shown that nucleic acids could be precipitated as quaternary ammonium salts, soluble in various organic solvents, and that they could be regenerated from these organic solutions as the sodium salts on addition of concentrated solutions of sodium chloride This treatment does not affect the infectivity of tobacco mosaic virus ribonucleic acid (RNA)[2]

We thought that it might be interesting to see if such a treatment could also be applied to soluble RNA (S-RNA) and to study its influence on the ability of S-RNA to accept amino-acids activated as amino-acyl adenylates

S-RNA was prepared from baker's yeast according to the technique of Monier *et al* [3] This S-RNA was precipitated by addition at 0° of trimethylhexadecylammonium bromide in the proportion of one quaternary ammonium group for one nucleotidic phosphorus The precipitate of quaternary ammonium ribonucleate, washed three times with distilled water, was soluble in absolute ethyl alcohol On the addition of an equal volume of 3 *M* sodium chloride solution, the S-RNA was regenerated as the sodium salt, and, after three washings with a mixture of equal volumes of ethyl alcohol and 3 *M* sodium chloride, it was redissolved in distilled water

The activity as valine-acceptor of the so-treated S-RNA was compared with that of a control S-RNA, under the following incubation conditions 100–150 μgm of S-RNA, 10 μmoles of adenosine triphosphate (ATP)-Mg^{++} and 0 333 μmole of ^{14}C-DL-valine (corresponding to 1 μc) were incubated in a final volume of 1 ml of *tris*-(hydroxymethyl)aminomethane hydrochloride buffer 0 025 *M* *p*H 7 6 containing 0 0025 *M* magnesium chloride, at 37° for 30 min , in the presence of a valine-activating enzymic preparation The enzymic preparation was the *S*4 fraction of rat ascites hepatoma cells, prepared according to Hecht *et al* [4] The S-RNA was precipitated and isolated, and its radioactivity measured under the conditions described by these authors[4]. The results obtained are summarized in Table 1

Table 1 ^{14}C-VALINE INCORPORATION RATE OF CONTROL S-RNA AND TREATED S-RNA

	C p m /mgm S-RNA	Incorporated valine (mμmoles)	
Control S-RNA	988 1,024	2 13 2 21	2 17
S-RNA precipitated by quaternary ammonium and regenerated	1,024 1,167	2 21 2 52	2 37

The biological activity of S-RNA was suppressed neither by the treatment with the quaternary ammonium salt nor by the dissolution in an organic solvent Instead, a slight increase of the specific activity was observed, in agreement with the chromatographic behaviour of the treated S-RNA and the control S-RNA on 'Ecteola'-cellulose columns[5,6]

The elution with a 0–1 *M* sodium chloride gradient of the control S-RNA showed evidence of a fraction which was eluted by low concentrations of sodium chloride and which was composed of oligonucleotides, inactive as amino-acid acceptors This fraction disappeared after precipitation of the S-RNA as quaternary ammonium salt and regeneration This precipitation would thus constitute a method of purification of S-RNA, which is equivalent, so far as the elimination of inactive oligonucleotides is concerned, to chromatography on 'Ecteola'-cellulose

In summary, after treatment with a quaternary ammonium salt, S-RNA can be dissolved in an organic solvent and regenerated from this solution as the sodium salt, without loss of its biological activity

Experiments are in progress to take advantage of this dissolution in an organic solvent and attempt a fractionation of S-RNA

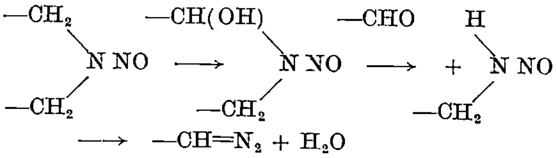
Mechanism of the Hepatoxic Action of Dialkylnitrosamines

Dimethylnitrosamine[1] and some other dialkylnitrosamines[2,3] cause centrilobular necrosis in rats Schoental and Rose[4] suggested independently that centrilobular necrosis was caused by diazo-alkanes formed by the metabolic oxidation of the nitrosamines in the liver *in vivo*[5,6] The sequence of reactions is presumed to be



On this sequence (*n*-butyl)(methyl)nitrosamine (BuMeN NO) should cause centrilobular necrosis, but (*tert*-butyl)(methyl)nitrosamine (Me_3C MeN NO) should not α-Oxidation of the *n*-butyl compound can give either diazomethane or diazobutane, according to which alkyl group is attacked In the *tert*-butyl compound the *tert*-butyl group cannot be attacked in the α position, and oxidation of the methyl group leaves a compound with no α-hydrogen atom, which cannot, therefore, yield a diazo-alkane

The two compounds were synthesized and tested on female rats (Porton Wistar strain) Both compounds were given intraperitoneally as solutions in normal saline

The *n*-butyl compound caused acute centrilobular necrosis in doses of 100–120 mgm /kgm in 1–2 days Doses of 60 mgm /kgm were without obvious effect This compound is about one-quarter as toxic as dimethylnitrosamine, and affects the liver in a very similar way

Twenty rats were treated with the *tert*-butyl compound Four died from the treatment they received, so the doses given were near the maximum tolerable Three survived 1,600 mgm /kgm given in divided doses over 4 days, and three others survived 1,400 mgm /kgm given over the same period The rest survived smaller doses given over shorter periods The survivors were killed at various times after the last dose—from the highest doses at 1, 3 or 10 days after Various lesions were observed on histological examination, but no centrilobular necrosis in any case Thus the *n*-butyl compound caused the typical lesion, but the *tert*-butyl compound did not, in accordance with the diazo-alkane theory

This evidence for the diazo-alkane theory is not, of course, conclusive It is possible that still higher doses of the *tert*-butyl compound might cause centrilobular necrosis Alternatively, perhaps the *tert*-butyl compound does not reach the sites in the liver at which metabolism takes place This last possibility is being investigated with nitrosamines labelled with carbon-14

I thank Dr P N Magee for carrying out the histological examinations, Dr A R Mattocks for preparing the specimens of nitrosamines, and Mr J Rose for technical assistance

PHYSIOLOGY

Cytotoxic Effect of Aminoacetonitrile on Fibroblast Cultures and its Prevention by Histidine

The understanding of the ætiological factors involved in the curious poisoning arising from the ingestion of *Lathyrus odoratus* seeds has been greatly advanced by the identification of β-amino-propionitrile as the active moiety of the toxic principle and the recognition of the even more potent lathyrogenic property of aminoacetonitrile (AAN)[1,2] However, the site and nature of the primary metabolic disturbance responsible for the characteristic mesenchymal lesions produced by aminonitriles have not yet been elucidated The present investigation was designed primarily to explore the possibility of using tissue cultures as a prospective tool for studying under *in vitro* conditions the biochemical mechanism underlying the toxic action of AAN

The experiments were performed regularly with chick embryo fibroblasts grown in a modified *M*–150 medium of Morgan *et al* [3] consisting of Hanks's salt solution, a mixture of amino-acids and vitamins and fortified with 2 per cent calf serum In most experiments 3–4 days-old cultures were used and AAN was added with fresh medium following the removal of the initial culture fluid Under such conditions

Table 1 PREVENTION OF CYTOTOXIC ACTION OF AMINOACETONITRILE BY HISTIDINE

3 0	4 0	+	+ +	+ +		

Suitable dilutions of aminoacetonitrile hydrosulphate and histidine hydrochloride neutralized with NaOH were added to 3-day-old cultures along with the replacement medium *M*-150 (ref 3) Incubation (at 37° C) was continued and the cultures were examined microscopically at the intervals indicated All experiments were performed in 5-replicate tubes

Key — No effect, +, scattered appearance of rounded cells but cell-sheet intact, + +, incipient loosening of cell texture, + + +, pronounced fragmentation of cell sheet, large number of loose rounded cells, + + + +, disintegration of cell sheet complete, rounded cells and cell debris

AAN (100 μgm per ml) produced a series of progressive alterations manifested by swelling of the nuclei, rounding of the cells and enlargement of their volume until the fibroblastic morphology was no longer recognizable concurrently, fragmentation of the cell-sheet became increasingly pronounced and finally complete disintegration of the culture took place at the end of 2–3 days after the addition of AAN With higher levels of AAN (150–400 μgm per ml medium) the course of the toxic phenomenon was considerably accelerated and short-circuited

The noxious effect of AAN was most prominent in young, actively proliferating fibroblasts and appeared to decrease with increasing age of the culture This observation may be correlated with the striking enhancement of AAN toxicity occurring in fibroblast cultures supplemented with microgram quantities of triiodothyronine, triiodothyronine has been shown previously to stimulate considerably the metabolic rate of chick fibroblasts[4] Both findings seem to suggest that high metabolic activity is essential for poisoning to occur It may be also relevant to mention in this connexion that the susceptibility to experimental lathyrism is highest in weanling rats and declines sharply with increasing age of the animals[5]

Mouse fibroblasts exhibited an essentially similar response to AAN although their sensitivity was of a somewhat lower order than that of the chicken fibroblasts On the other hand, two epithelial lines tested (kindly supplied by Dr J F Morgan), namely, human kidney cells and the *FL* strain of human amnion cells, proved to be refractory to AAN even at doses threefold higher than those lethal for chick fibroblasts

Of particular interest was the observation that addition of an enzymic hydrolysate of lactalbumin to the culture medium (10–20 mgm per ml) resulted in a significant delay or even complete prevention of the toxic phenomenon induced by AAN under the usual test conditions The latter finding, which appears to bear directly on the mode of action of AAN, may be related to the repeated observations that the course and severity of the *Lathyrus* poisoning in rats can be modified considerably or attenuated by maintaining the animals on protein-rich diets[6,7]

The protective effect of lactalbumin could be duplicated by raising the amino-acid concentration in the culture medium Furthermore, out of 20 natural amino-acids tested singly or in various combinations, only histidine overcame the cytopathic action of AAN As shown in Table 1, L-histidine at 2 × 10^{-3} *M* gave complete protection against 7 × 10^{-4} *M* AAN When tested against graded amounts of AAN, the effective dose of histidine varied in a roughly parallel manner with the changing levels of AAN

Further work revealed that D-histidine is equally effective as its natural (L-) enantiomorph in counteracting the toxicity of AAN Histamine and imidazole, on the other hand, failed to exhibit a protective effect

It may be concluded, therefore, that the ability of histidine to prevent the cytotoxic action of AAN is probably unrelated to its role as an essential amino-acid since the latter property is known to be stereospecific with respect to the L-configuration[8] The possible relationship of the protective property of histidine to its well-known metal-binding capacity[9] is being examined

Addendum Recent experiments revealed that the cytotoxic action of AAN on fibroblasts requires the presence of traces of copper ions in the culture medium In the light of the latter finding, the protective effect of histidine appears to be attributable to its copper-chelating property

Incorporation of ^{14}C-glycine by Sub-Nuclear Preparations from Rat Liver Nuclei

IT has been shown previously[1] that rat liver nuclei isolated in 0 25 *M* sucrose solution will incorporate ^{14}C-glycine into protein *in vitro* The possibility of non-specific exchange of glycine was eliminated[2] It was shown that radioactivity was retained after re-incubation of labelled nuclei for 2 hr in a 200-fold excess of unlabelled glycine The incorporation of glycine by nuclear preparations was inhibited by 2,4-dinitrophenol (DNP), azide, and anoxia

The ability to incorporate glycine was retained after the nuclear preparations had been subjected to various treatments Suspending the nuclei in water, freezing and thawing this preparation up to four times, or even freeze-drying and resuspending the nuclei in water did not reduce the ability to incorporate by more than 30 per cent Treatment with a detergent, 'Triton *X* 100', was no more effective Microscopic examination showed these treated nuclei to be structurally intact

In a further attempt to disrupt the nuclei, the preparation was subjected to sonic disintegration Microscopic examination showed that complete disintegration was obtained after 15 min at 20,000 oscillations per sec using a Mullard ultra-sonic disintegrator This sonicate incorporated ^{14}C-glycine without any loss of activity compared with the intact nuclei (Table 1)

Table 1

Preparation	Counts/min at infinite thickness
Intact nuclei	192
Sonically disintegrated nuclei	204
Supernatant after 6 3 × 10^6 g_{av} min *	171
Supernatant after 4 41 × 10^7 g_{av} min	156
Residue after 4 41 × 10^7 g_{av} min	380

For incorporation of 2-^{14}C-glycine into nuclear protein the system used was sodium phosphate buffer, *p*H 7 4, 20 m*M*, NaCl, 20 m*M*, ^{14}C-glycine, 1 μc , 1 5 ml of a sub-nuclear suspension in 0 25 *M* sucrose, water to 2 5 ml , temperature, 38° C , for determination of radioactivity, see Rees and Rowland (ref 1)

* Centrifugal force developed at the mid-point of the tube

The sonicate was centrifuged at 105,000*g* for 60 min in a 'Spinco' model *L* ultra-centrifuge at 0° C Using the same incubation medium as for intact nuclei, the supernatant was able to incorporate ^{14}C-glycine and this incorporation was not inhibited by DNP or anoxia Centrifugation of this supernatant for 7 hr at 105,000*g* yielded a pellet which on re-suspension in 0 25 *M* sucrose very actively incorporated ^{14}C-glycine The supernatant also retained ability to incorporate (Table 1)

Sub-nuclear particles have been prepared from calf-thymus nuclei by extraction with *tris* buffer (*p*H 7 1)[3] These particles incorporate amino-acids but, in contrast to the preparations described in this paper, they require a system containing the nuclear *p*H 5 enzymes[3], adenosine triphosphate, guanosine triphosphate and a source of generating adenosine triphosphate

Fate of Tritiated Noradrenaline at the Sympathetic Nerve-Endings

Previous work in this Laboratory has shown that tritiated adrenaline and tritiated noradrenaline are taken up and retained in certain tissues for long periods of time[1,2] It was also demonstrated that chronic denervation of sympathetic nerves resulted in the decreased ability of denervated tissues to take up administered tritiated noradrenaline and adrenaline[3] These observations indicated that sympathetic nerve-endings selectively took up and retained circulating catecholamines This property enabled us to label the nerve-endings with tritiated noradrenaline and to study its fate on liberation from sympathetic nerves

In the experiments described here cats were given tritiated noradrenaline, the splenic nerve stimulated in the manner described by Brown and Gillespie[4], and the tritiated noradrenaline and its metabolites measured in the venous outflow Because of the relatively large amount of tritiated noradrenaline present in the blood supplying and leaving the spleen, this organ was isolated and perfused with blood from a donor cat that was free of radioactive material Cats were given 200 μc /kgm DL-^{3}H-noradrenaline (20 mc /mgm) in the forelimb vein Three hours later the animals were anæsthetized with pentobarbitone and given 3000 U S P units of heparin The small and large intestines were tied off and removed The blood vessels between the spleen, stomach and omentum were tied and cut Polyethylene tubing ('*PE* 200' Clay-Adams) was inserted into the superior mesenteric vein and the tubing clamped The superior mesenteric artery was tied off close to the aorta and cut, and the splenic artery was separated from the connecting tissues Polyethylene tubing ('*PE* 20') filled with heparinized saline was inserted into the artery branching from the splenic artery to the stomach and was used to inject drugs into the spleen A second cat received pentobarbitone and heparin, and its femoral artery cannulated with polyethylene tubing ('*PE* 200') and connected to the splenic artery of the first cat The blood supplied from the donor cat was replaced by blood obtained from a third cat The portal vein of the first cat was tied and cut, and the tubing in the mesenteric vein opened After the remaining connexions were tied and cut, the spleen was placed in a saline water bath at 37° C The splenic nerve was placed on a dipolar platinum electrode and was coated with paraffin The splenic nerve was stimulated with 10 V for a duration of 1 msec a stimulus and a frequency of 10 or 30/sec An equal number of

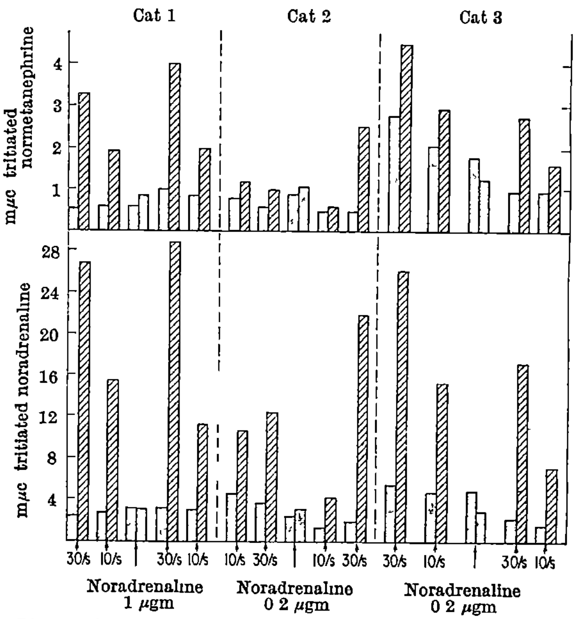

Fig 1 Release and *O*-methylation of tritiated noradrenaline after stimulation of the splenic nerve Cats were given tritiated noradrenaline intravenously and the spleen was prepared as described in the text Splenic nerves were stimulated at a frequency of 10 or 30/sec Cats 1 and 3 received a total of 300 stimuli for each period and cat 2 received 200 stimuli Blood was collected 2 5 min before and 2 5 min during and after stimulation from cats 1 and 3 and 2 0 min for each period from cat 2 Non-radioactive noradrenaline was injected into the splenic artery Each bar represents tritiated noradrenaline or tritiated normetanephrine in mμc found in each period Stippled bars are tritiated noradrenaline and tritiated normetanephrine measured before stimulation, and striped bars are tritiated noradrenaline and tritiated normetanephrine during and after stimulation

stimuli was given in all cases. A Grass stimulator, model *S 4B*, was used. Blood was collected for 2.0 or 2.5 min before and 2.0 or 2.5 min during and after stimulation. There was a 7-min interval between each group of stimuli. Blood was collected in graduated centrifuge tubes containing two drops of heparin solution and the hæmatocrit was determined. An aliquot of plasma was deproteinized with 10 ml of 0.4 *N* perchloric acid and tritiated noradrenaline was determined as described in refs. 1, 2. Tritiated normetanephrine was estimated on the effluent from the alumina column by adsorption on 'Dowex 50' (ref. 5). Results are expressed as mμc tritiated noradrenaline released or tritiated normetanephrine formed in each period.

After each stimulation there was a marked increase in the concentration of tritiated noradrenaline in the venous outflow (Fig. 1). A greater amount of the tritiated catecholamine was released after 30 stimuli/sec than after ten stimuli. During each stimulation period there was a contraction of the spleen. The release of tritiated noradrenaline, however, was unrelated to this contraction since a similar contraction induced by the administration of non-radioactive noradrenaline directly into the splenic artery did not increase the outflow of tritiated noradrenaline (Fig. 1). There was a small amount of tritiated noradrenaline released spontaneously without stimulation.

After each stimulation there was a concomitant increase in tritiated normetanephrine (Fig. 1). The amount of tritiated normetanephrine found was directly related to the amount of tritiated noradrenaline released. The de-aminated metabolites (3,4-dihydroxyphenylglycol and 3,4-dihydroxymandelic acid) in the venous outflow were also determined[5]. The amount of these compounds found were small (0.2 mμc/period) and were not elevated during stimulation.

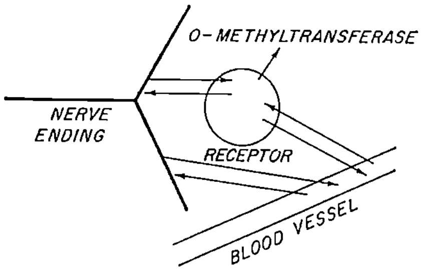

Fig. 2. Fate of noradrenaline at the sympathetic nerve ending

Our earlier work has shown that sympathetic nerve endings or neighbouring structures take up and bind circulating catecholamines[1-3]. In this communication we have demonstrated that stimulation of these nerves releases tritiated noradrenaline which was taken up previously from the circulation. This indicates that the neurohumour, noradrenaline, can be taken up from the blood-stream, bound and then released on stimulation. The *O*-methylated metabolite tritiated normetanephrine was also elevated after each series of stimulations.

It can be concluded that the noradrenaline liberated from the nerve endings reacts with the receptor, and a part is discharged into the bloodstream, a part *O*-methylated by catechol-*O*-methyl transferase[6] and a part bound again at the sympathetic nerve endings. The fate of noradrenaline at the sympathetic nerve ending is shown schematically (Fig. 2).

We wish to thank Mr. R. W. Patrick for his competent technical help.

Phenylalanine as Inhibitor of Transport of Amino-Acids in Brain

In phenylketonuria the tissues are unable to metabolize phenylalanine to tyrosine, resulting in abnormally high levels of phenylalanine in body fluids, together with a number of disorders of tyrosine metabolism[1,2].

It has been shown that certain amino-acids can interfere with the transport of other amino-acids in tissues[3,4]. Thus it is possible that the high levels of phenylalanine in phenylketonuria might produce a similar type of interference and result in abnormal metabolism of free amino-acids generally.

To determine whether such an interference might occur, the effect of phenylalanine on the uptake of five amino-acids by brain tissue has been investigated, using an *in vitro* technique described elsewhere[5]. Slices of rat brain were agitated for 1 hr. at 37° C. in Krebs's bicarbonate saline which contained the amino-acids under investigation. The concentration of the particular amino-acid being investigated was then estimated in tissue and suspending medium by a colorimetric method[6-8]. There was no evidence that phenylalanine when present in equimolar amounts interfered with the estimation of any of the other amino-acids; at a concentration ten-times higher it interfered only with the estimation of arginine, but to a negligible extent. Recoveries of appropriate amounts of tyrosine added to tissue initially agitated for 1 hr. in medium free of amino-acid were found to be low (87–88 per cent), values found for tyrosine in tissue have therefore been corrected by the corresponding factor. Recoveries of the other amino-acids were satisfactory. The *p*H of the suspending medium (critical in this type of experiment[5]) was measured at the end of all experiments and lay within the range 7.3–7.4. The mean blank value in tissue fluid of each amino-acid being estimated was not greater than 0.35 m*M*.

Results have been expressed in the form of the 'concentration difference' (concentration of amino-acid in tissue fluid minus concentration of amino-acid in suspending medium), which is an indication of the net effectiveness of the transport mechanism for the particular amino-acid being investigated.

Table 1 shows that phenylalanine not only interferes with transport into brain tissue of all the amino-acids investigated, but also that it inhibits uptake of tyrosine considerably more than that of any of the other four amino-acids. It follows that the high phenylalanine-level of phenylketonuria probably causes a similar interference with movements of tyrosine and, to a smaller extent, of other amino-

Table 1 EFFECT OF PHENYLALANINE ON TRANSPORT OF AMINO-ACIDS

Amino-acid	Concentration difference developed between slices and suspending medium (m*M*)		Inhibition by L-phenylalanine (per cent)
	When present alone	In the presence of an equimolar amount of L-phenylalanine	
L-Proline	8 48 ± 0 73 (16)	7 71 ± 0 67 (16)	9
L-Histidine	15 6 ± 1 1 (12)	9 0 ± 1 6 (20)	42
L-Arginine	2 70 ± 0 56 (16)	1 47 ± 0 32 (15)	46
L-Ornithine	3 44 ± 0 31 (12)	1 82 ± 0 14 (12)	47

acids in brain and other tissues of the body The considerable interference with tyrosine transport would be of greater significance in those tissues such as brain and intestinal mucosa which transport tyrosine the most actively[9] With tissues in which there does not appear to be active transport of tyrosine[9], movement of tyrosine would probably not be affected, as has already been shown with liver[10]

Stability of Dextran during Prolonged Storage

So far as we are aware, no measurements relating to the stability of clinical dextran solutions kept for several years have been published Two dextran solutions made in the United States, *A* and *B*, and two made in Great Britain, *C* and *D*, were examined in 1954, and again after storage for 5 yr at 4° C Where applicable the methods of testing described in the British Pharmacopœia[1] were used The optical rotation of each dextran was determined and used in calculating the concentrations of solutions for the viscosity measurements (Table 1) Dextran *D* had undergone the most change, the changes in the others were relatively small

The renal excretion of these dextrans was measured in rabbits (Table 2) The greater part of the dextran was excreted on the first day, less than 3 per cent on the second and less than 1 per cent on the third day Two, three or four rabbits were used for each determination and the daily results averaged, Table 2 records the totals for 3 days after injection The results for dextran *A* suggest a change in molecular composition, but no corroboration of this was found in the other measurements

Table 1

Dextran	Optical rotation (*a*)	Intrinsic viscosity at 25° C 1954	Intrinsic viscosity at 25° C 1959
A	195 1	0 249	0 248
B	197 7	0 254	0 251
C	201 2	0 394	0 388
D	198 1	0 362	0 326

Table 2

Dextran	Percentages of injected dose excreted 1954	Percentages of injected dose excreted 1959
A	37 2	47 6
B	43 1	39 1
C	13 5	14 6
D	15 9	15 4

The retention of each dextran in the plasma was determined by taking the average of daily estimations in the same groups of rabbits (Table 3) During five years of storage little if any change had occurred in the dextrans affecting their retention in the circulation

Table 3 PLASMA CONCENTRATION OF DEXTRAN AS PERCENTAGE OF CONCENTRATION 10 MIN AFTER INJECTION

Dextran		10 min	Day 1	2	3	4	5	6	7
A	1954	100	28 8	11 7	0 4	0 0	0 0	0'0	0 0
	1959	100	29 6	15 2	2 25	0 8	0 0	0 0	0 0
B	1954	100	29 2	13 8	3 6	0 0	0 0	0 0	0 0
	1959	100	30 0	14 1	2 0	0 6	—	—	0 0
C	1954	100	56 8	34 8	12 3	3 8	0 7	—	0 0
	1959	100	61 0	40 9	18 3	10 0	—	—	0 6
D	1954	100	60 5	40 2	22 8	12 8	5 1	—	0 8
	1959	100	56 5	38 7	22 0	—	—	3 3	1 5

The difference in molecular composition of American and British dextrans is well illustrated by these results The lower average molecular weight of the American dextrans is associated with shorter retention in the circulation and greater renal excretion The British dextran, of higher average molecular weight, would induce greater aggregation of red cells *in vitro*[2] and possibly *in vivo*, too

From our observations we conclude that during the 5-yr period there was little, if any, change in the molecular composition of these dextran solutions and none that would be noticeable in clinical use It is probable that any limitation of the storage 'life' of dextran solution will be imposed by defects in the container and its closure rather than by any instability of dextran solution itself

PHARMACOLOGY

Effects of 7-Chloro-2-methylamino-5-phenyl-3H-1,4-benzodiazepin-4-oxide on Mitochondria from Rat Liver and Brain

ALTHOUGH little is known about the relations between *in vivo* drug action and the effects of a drug on metabolic processes *in vitro*, it has been confirmed that psychopharmacological materials in many cases act on oxidative reactions in the mitochondrial respiratory chain The two different drugs, amytal and chlorpromazine, both, for example, have inhibi-

Table 1 EFFECT OF CMPB ON UPTAKE OF OXYGEN, RESPIRATORY CONTROL AND PHOSPHORUS/OXYGEN RATIO OF LIVER AND BRAIN MITOCHONDRIA

The phosphorylation medium consisted of phosphate-buffer, *p*H 7 4, 20 m*M*, *tris*-buffer, *p*H 7 4, 20 m*M*, adenosine diphosphate, 2 m*M*, substrate, 10 m*M*, except β-hydroxybutyrate, 30 m*M*, and malate together with pyruvate, 1 m*M*, glucose, 28 m*M*, and hexokinase in excess Each tube contained mitochondria from 100 mgm (glutamate), 135 mgm or 200 mgm (brain) wet-weight tissue, and sucrose, 50 m*M* In the case of respiratory control adenosine diphosphate and hexokinase were omitted The final volume was 1 ml The vessels were incubated for 15 min at 30°

Substrate	m*M* CMPB	Liver			Brain		
		Uptake of oxygen (μatoms)	Respiratory control (μatoms)	P/O	Uptake of oxygen (μatoms)	Respiratory control (μatoms)	P/O
Glutamate	0	2 3	0 1	2 2			
Glutamate	1	1 3	0	2 2			
Malate	0	3 6	1 4	2 1			
Malate	1	2 5	1 0	2 0

Pyruvate + malate	2 0	1 4	0 8	2 5	1 1	0 6	1 4

tory effects on the flavoprotein in the respiratory chain[1,2] Therefore it was of interest to test whether the new drug, 7-chloro-2-methylamino-5-phenyl-3H-1,4-benzodiazepin-4-oxide (CMPB, used as hydrochloride)[1] acts on mitochondrial reactions in a similar manner

CMPB, a drug of a new chemical group, has been tested in concentrations up to 1 m*M* With higher concentrations a precipitate is formed at the physiological *p*H 7 4 Rat liver mitochondria were prepared according to the method described by Ernster and Low[3] Rat brain mitochondria were isolated in 0 25 *M* sucrose containing 1 m*M* ethylenediaminetetra-acetic acid (EDTA)[2] between 1,400 and 12,000*g*

As shown in Fig 1, CMPB is a potent swelling agent on liver mitochondria The swelling effect, however, could be prevented completely by 1 m*M* EDTA (Fig 1*b*), which is in accordance with earlier findings on a variety of other swelling agents[4] Lehninger[5] has shown that mitochondrial swelling produced by various agents in a buffered saline medium, but not in 0 3 *M* sucrose, could be reversed by adenosine triphosphate and magnesium In Fig 1*C* it can be seen that in a potassium chloride medium, swelling induced by CMPB could be reversed partially by adenosine triphosphate alone and more effectively by adenosine triphosphate with magnesium Using brain mitochondria, no swelling could be obtained even with higher concentrations of CMPB (2 m*M*), however, 20 m*M* phosphate, too, which causes a rapid swelling of liver mitochondria, had no effect on brain mitochondria A resistance of brain mitochondria against swelling agents has been observed recently by Spirtes[6]

The effect of CMPB on mitochondrial oxidation and phosphorylation and the respiratory control is shown in Table 1 There is a distinct inhibition of the oxidation-rates with substrates linked with diphosphopyridine nucleotide (DPN), however, no inhibition is found using succinate as substrate Whereas the phosphorylation with the DPN-linked substrates is almost unaffected, with succinate there is a slight but obvious depression of the ratios of phosphorus to oxygen Similar results are obtained concerning the respiratory control Only with succinate a marked loss of the respiratory control could be detected With brain mitochondria analogous results were obtained

To find out the site of action of CMPB, the 2,4-dinitrophenol (DNP)-induced adenosine triphosphatases of both types of mitochondria were examined, because it has been suggested, from the DNP-induced adenosine triphosphatase, to occur only at the first phosphorylation step at the flavin region[7] As shown in Table 2, the DNP-induced adenosine triphosphate is markedly depressed by CMPB This effect is even higher with brain mitochondria Amytal, which is known to have an inhibitory effect on the flavoprotein of the respiratory chain[1], stimulates the effect of CMPB

From these observations it is suggested that CMPB has two points of action at the respiratory chain of mitochondria It seems to inhibit the redox reactions of the flavoprotein However, the reactions which transfer the high-energy phosphate at the flavoprotein level probably are not influenced by this drug, because of the small uncoupling effect on the phosphorylation with DPN-linked substrates compared with succinate Low[7] has proposed a scheme of the DNP-induced adeno-

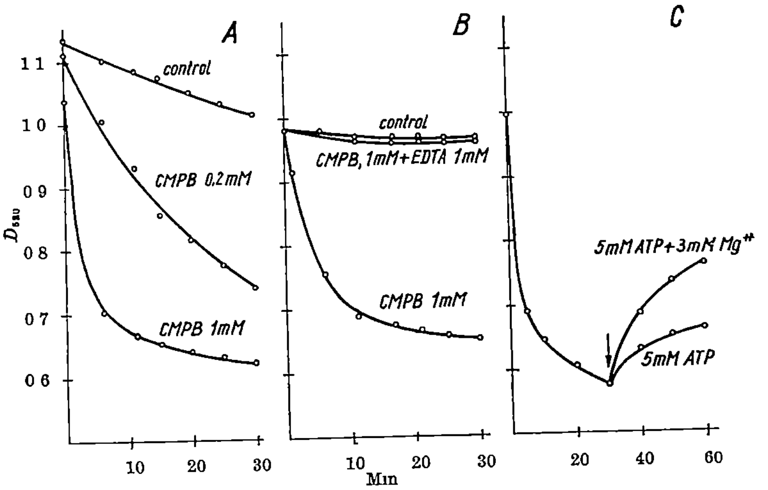

Fig 1 Effect of CMPB on swelling of liver mitochondria *A*, effect of various concentrations, *B*, prevention of swelling by EDTA, *C*, reversal of swelling by adenosine triphosphate and magnesium The swelling medium consisted of *tris*-buffer *p*H 7 4, 0 02 *M* in 0 3 *M* sucrose (*A* and *B*), or in 0 125 *M* potassium chloride (*C*) Mitochondrial swelling was carried out in 1-cm tubes at 520 mμ at room temperature

Table 2. EFFECT OF CMPB ON THE DNP-INDUCED ADENOSINE TRIPHOSPHATASE

Each tube contained mitochondria from 100 mgm (liver), or 200 mgm (brain) wet-weight tissue, adenosine triphosphate, 5 m*M*, *tris*-buffer, *p*H 7·4, 5 m*M*, DNP, 0·1 m*M* in 1 ml. 0·25 *M* sucrose, and was incubated for 20 min. at 30°

Additions	m*M* CMPB	μmoles inorganic phosphate liberated	
		Liver	Brain
	0	2·05	1·59
	0·1	1·95	1·34
	0·5	1·76	1·22

sine triphosphatase reaction. In agreement with that scheme it may be suggested that the reaction between the flavoprotein and the reduced diphosphopyridine nucleotide may be the one inhibited by CMPB. The second point of action of this substance seems to be the phosphorylation steps between cytochrome *b* and the cytochrome oxidase, which is suggested from the uncoupling effect on succinate-linked phosphorylation.

No marked difference between the effects on mitochondrial reactions from brain and liver has been found. This seems to indicate that the effects shown here may have a common meaning as applied to mitochondria from different origins. Although we are not able to explain the special psychopharmacological action of this drug *in vivo* by the results obtained *in vitro*, it is of interest to note that chlorpromazine, a chemically completely different compound, which has similar pharmacological effects, acts on mitochondria in a surprisingly analogous way[8-10].

CMPB, available under the trade name 'Librium(R)', was a gift from the Deutsche Hoffmann-La Roche AG.

We thank Mrs. Brigitte Kuhn for skilful technical assistance.

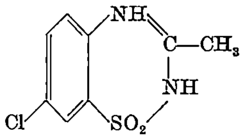
A Non-diuretic Benzothiadiazine with Anti-hypertensive Properties

IN recent years the benzothiadiazine diuretics have become the drugs of choice for treating mild to moderate hypertension. Although their anti-hypertensive effect is relatively weak, they are quite non-toxic and are well absorbed orally. The mechanisms by which these agents reduce blood pressure in hypertensive individuals are not known. Some investigators[1,2] have implicated natriuresis as the primary event, whereas others[3] have suggested that the concentration of circulating pressor agents is reduced. That benzothiadiazine diuretics do antagonize *in vitro* intestinal and aortic contractions has already been demonstrated[4,5]. Consequently, the possibility exists that these agents directly affect the responsiveness of vascular smooth muscle. It was, therefore, considered of interest to try to dissociate the anti-hypertensive and diuretic actions of these compounds and, further, to intensify the former action while minimizing the latter.

Accordingly, several types of benzothiadiazine analogues were synthesized by Dr. J. G. Topliss, M. H. Sherlock and Dr. N. Sperber of the Chemical Research Division, Schering Corporation, and afterwards evaluated for anti-hypertensive and diuretic activities. It soon became apparent that certain structural modifications of the benzothiadiazine nucleus produced a class of compounds that lowered arterial blood pressure acutely in laboratory animals. The most critical structural change involved the elimination of the sulphamyl group from the benzenoid moiety. A representative member of this des-sulphamyl benzothiadiazine series which has received considerable attention in our laboratories is 3-methyl-7-chloro-1,2,4-benzothiadiazine-1,1-dioxide (*SRG* 95213). This agent has virtually no natriuretic or diuretic activity. Indeed, it caused slight sodium and urine retention in acute experiments on hydrated rats.



In acute work on more than 100 anæsthetized, normotensive cats and dogs, intravenous injections of *SRG* 95213 (2·0–10·0 mgm./kgm.) caused an immediate and prolonged fall in arterial blood pressure. In contrast, benzothiadiazine diuretics, in doses as high as 40·0 mgm./kgm., produced little or no change in blood pressure under the same experimental conditions. In chronic work on hypertensive dogs (Goldblatt renal preparations) and rats (active deoxycorticosterone acetate and metacorticoid hypertension), daily oral administration of 5·0–20·0 mgm./kgm. of *SRG* 95213 resulted in a gradual and sustained reduction in blood pressure followed by a gradual recovery to pre-treatment-levels after the drug was discontinued (Figs. 1 and 2).

In other experiments designed to elucidate the mechanisms whereby this agent produces its characteristic effects, it was observed that *SRG* 95213-induced hypotension in anæsthetized cats was not blocked by previous administration of atropine, phentolamine, hexamethonium, chlorpheniramine, reserpine or by transection of the cervical spinal cord. In addition, direct injections of *SRG* 95213 into the femoral, renal and coronary arteries of anæsthetized dogs caused immediate and prolonged increases in the rate of flow of blood through each vascular bed. The results of this work suggest that *SRG* 95213 does not primarily influence nervous pathways or humoral factors in producing its hypotensive effect, but rather induces a direct peripheral vascular relaxation. *In vitro* experiments on rat and rabbit aortic strips tend

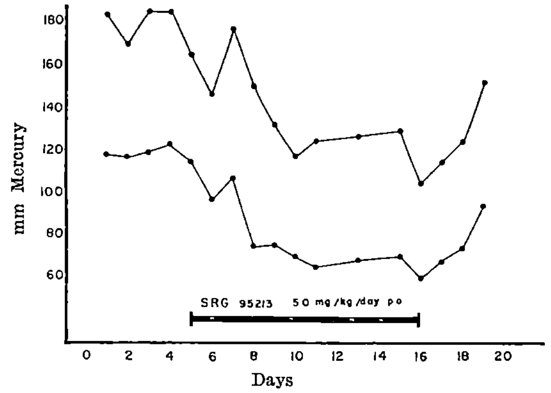


Fig 1 Anti-hypertensive effect of *SRG* 95213 on the systolic and diastolic pressures of one renal hypertensive dog

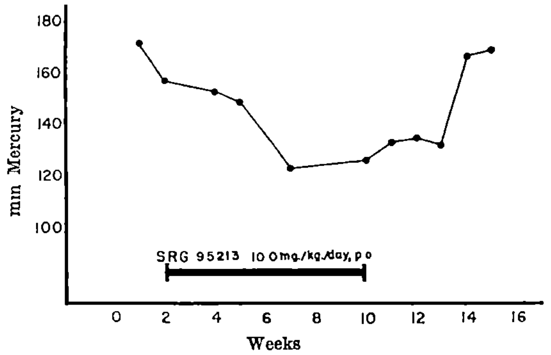

Fig 2 Anti-hypertensive effect of *SRG* 95213 on the mean systolic blood pressure of 9 DOCA hypertensive rats

to support this thesis by demonstrating *SRG* 95213 antagonism to contractions induced by several different classes of vasoactive agents, for example, norepinephrine, angiotensin and serotonin

In summary, it has been shown that *SRG* 95213, although structurally similar to the benzothiadiazine diuretics, is, in fact, non-diuretic but does reduce blood pressure in normotensive as well as hypertensive animals Preliminary clinical observations in hypertensive individuals have, so far, confirmed the results obtained with animals It is therefore not unreasonable to assume that *SRG* 95213 represents a true separation of the anti-hypertensive and diuretic properties associated with benzothiadiazine diuretics The possibility does exist, however, that *SRG* 95213 possesses an anti-hypertensive action unlike that of the benzothiadiazine diuretics and, therefore, may be representative of a new class of anti-hypertensive agents

RADIOBIOLOGY

Effect of γ-Radiation on *Escherichia coli* grown in Deuterium Oxide Medium

IT has been shown by several authors, for example by Alper and Gillies[1], that the nature of the growth medium has an effect on the radiation sensitivity of bacteria with regard to their ability to divide and form colonies A simple, and yet considerable, change in the growth medium is the substitution of D_2O for H_2O It was found that, on transferring cells from normal minimal medium (NH_4Cl 2 gm , Na_2HPO_4 6 gm , KH_2PO_4 3 gm , NaCl 3 gm , $MgCl_2$ 10 mgm , Na_2SO_4 26 mgm , glucose 5 gm per litre) to the same made in 99 5 per cent D_2O, the cells grew, after a long lag period, with a generation time of 4 hr at 37° C , which is about five times the normal Similar results were found by Borek and Rittenberg[2] Such cells, after growth, must possess very considerable substitution of deuterium for hydrogen, with consequent modification of hydrogen-bonded molecular structures as well as any changes due to the increased rotational moment of inertia of water The greatly reduced rate of division could be due to slowed enzyme kinetics, to less efficient protein synthesis, or to some modification in the DNA, among other reasons Since it is likely that radiation action, as regards cell division, is concerned with the DNA or its organization, it seemed of interest to see whether cells grown in D_2O showed any differences in radiation sensitivity

The results of two separate experiments, in which cultures grown in H_2O and D_2O were simultaneously irradiated in a cobalt-60 source, are shown in Table 1

Table 1

Dose (r)	Survival (per cent) D_2O First experiment	Survival (per cent) H^2O	Survival (per cent) D_2O Second experiment	Survival (per cent) H_2O
5,000	15 0	8 0	28	23
10,000	4 8	2 1	5 1	3 9
15,000	1 5	$3 7 \times 10^{-1}$	0 7	1 1
20,000	$2 1 \times 10^{-1}$	$1 6 \times 10^{-1}$	$1 1 \times 10^{-1}$	0 26
25,000	$2 5 \times 10^{-2}$	$3 5 \times 10^{-2}$	$3 7 \times 10^{-2}$	$1 1 \times 10^{-1}$
30,000	$7 1 \times 10^{-3}$	$1 1 \times 10^{-2}$	$4 4 \times 10^{-3}$	$2 8 \times 10^{-3}$

Both types of bacteria are inactivated, to a first approximation, according to the relation $\ln(n/n_0) = -(\text{constant})\ (\text{dose})$, when n is the number of surviving colony-forming units for a given dose, and n_0 is the number present for no dose The average 37 per cent doses, for which $\ln(n/n_0) = -1$, are 3,040 r for H_2O bacteria and 3,230 r for D_2O The difference is not significant.

In these experiments the bacteria were diluted in H_2O medium and plated on H_2O agar Since the return transition to H_2O might be thought to affect the colony count, the colony counts so found were checked against the turbidity of the culture, which is measured in D_2O The plate counts matched the expected turbidity. Microscopic observations showed no visible alteration in the bacteria grown in D_2O It is believed, therefore, that the colony counts made in this way are significantly related to survival Whether cells plated on D_2O agar would show a difference cannot be said here

In addition to these experiments the relative radiation sensitivity while the cells were adapting to D_2O was measured, and the results are shown in Table 2

These results involve separate observations from the previous series The variation in D_{37} is probably only

Table 2 RELATIVE RADIATION SENSITIVITY OF BACTERIA WHILE ADAPTING TO D_2O

Time (hr)	Control colony count	D_{37} (roentgens)
0	$1\ 4 \times 10^6$	3,000
16	$1\ 8 \times 10^6$	4,100
23	$1\ 6 \times 10^6$	6,000
39	$9\ 0 \times 10^6$	4,900
47	$4\ 3 \times 10^7$	3,700

significant as regards the 23-hr stage, just before the cells began to grow and divide in the new medium This kind of behaviour has already been reported for normal cells by Stapleton[3] and cannot be ascribed to any special effect in D_2O

These experiments suggest that the DNA in deuterium-grown bacteria is not markedly different, using radiation sensitivity as an indicator, from that in normally grown bacteria The considerable modification in growth-rate, therefore, still offers a challenge in interpretation

Acknowledgement is made of the assistance of Mrs Anne Porter in the bacterial assays

Specificity of Plant Feeding in Mosquitoes as determined by Radioactive Phosphorus

THE development of resistance to insecticides in mosquito populations has made it increasingly apparent that alternative methods of control are required In this connexion, the plant-feeding habits of mosquitoes might offer a possible approach to control by biological means If specificity could be proved in the plant-feeding habits of any mosquito species, the extermination of such plants might lead to the control of that species

It is generally assumed in entomological literature that mosquitoes, especially the males, feed on nectar from flowers In work using phosphorus-32 on the feeding habits of arctic mosquitoes, West and Jenkins[1] claimed that, under laboratory conditions, both males and females of *Aedes communis* DeGeer ingested the juices and nectar from flowers of several species of arctic plants The present communication gives results of preliminary experiments, done in the Biology Branch of Atomic Energy of Canada, Ltd , Chalk River, Ontario, to investigate the plant-feeding habits of *Aedes aegypti* L reared in the laboratory and of native *Aedes* species from this area

In these experiments, the flowers and leaves of 24 different species of native plants were labelled with phosphorus-32 solutions at a concentration of 20 μc /ml Preliminary tests with cotton wicks, using different concentrations of phosphorus-32 (as $H_3{}^{32}PO_4$) in 5 per cent dextrose solution, had proved that this concentration gave easily detectable counts in both male and female mosquitoes, which fed on the dextrose solution

So far as possible, plants found in bloom around the breeding places of mosquitoes were used for the experiments These were brought into the laboratory and their stems were cut short under water The flowers and/or leaves of these plants were placed in 2-ounce bottles with the ends of the stems, wrapped in cotton, immersed in 30 ml of phosphorus-32 solution The mouths of the bottles were covered with cheese cloth to prevent the mosquitoes from coming in direct contact with the radioactive solution Without exception, the flowers and leaves of these plants took up appreciable amounts of radioactivity, reaching in some species about 25,000 count/min /cm ^{2} of leaf However, the presence of radioactivity in the nectar was not specifically determined

Larvæ of native mosquitoes were collected from temporary pools and swamps and reared together to the adult stage in the laboratory Three species of *Aedes* were identified in these collections These were *Aedes implacabilis* (Walker), *Aedes dianteus* H D and K , and *Aedes punctor* (Kby) The native species were tested as a mixed population and separate tests were carried out with pure cultures of *Aedes aegypti*

For each feeding experiment 30 adults, including both males and females approximately one to two days old, were removed from the stock emergence cage to small laboratory cages (about 11 in × 11 in × 26 in) having sliding plastic fronts These mosquitoes, previously fed on 5 per cent dextrose solution, were left for 24 hr without food before the start of any experiment After a 24-hr period of confinement with the plants, the mosquitoes were killed, washed in three changes of distilled water, dried between filter papers, and mounted under cellulose tape on counting planchets This method of mounting was also used for the plants where, in most cases, the phosphorus-32 uptake of whole flowers and unit samples of leaves (1 cm ^{2}) were measured

Counts of radioactivity were made with a Geiger–Muller end-window tube (3 1 mgm /cm ^{2}) and a Marconi scaler All counts were corrected for background and decay of phosphorus-32 The plants used are listed in Table 1

Table 1

Acer rubrum L
Amelanchier bartramiana (Tausch) Roemer
Amelanchier canadensis (L) Medic
Amelanchier laevis Vieg
Clintonia borealis (Ait) Raf
Comptonia peregrina (L) Coulter
Corydalis sempervirens (L) Pers
Corylus sp
Cypripedium acaule Ait
Epigaea repens L
Erythronium americanum Ker-Gawl
Fragaria americana (Porter) Britton
Geranium bicknelii Britton
Osmunda cinnamomea L
Prunus depressa Pursh
Salix humilis Marsh
Spiraea latifolia (Ait) Borkh
Streptopus roseus Michx
Taraxacum officinale Weber
Trillium grandiflorum Michx
Vaccinium angustifolium Ait
Viburnum alnifolium Marsh
Viola conspersa Reichereb, J E Smith

Results of these laboratory tests showed that feeding had taken place on only three species of plants, namely, *Viola conspersa*, *Trillium grandiflorum*, and *Spiraea latifolia* All mosquitoes confined with these three plant species became radioactive, the average counts of the mosquitoes are shown in Table 2

Table 2

	Aedes aegypti	Native *Aedes* sp
Viola conspersa (American dog violet)	517 counts/min	114 counts/min
Trillium grandiflorum (white trillium)	315 ,,	8 ,,
Spiraea latifolia (meadow-sweet)	54 ,,	32 ,,

An important finding in these laboratory experiments was that, in all cases, the mosquitoes confined with flowers alone did not receive any radioactivity, on the other hand, placing leaves with the respective flowers of these three species of plants or the use of leaves only gave positive results This evidence indicates that, under the conditions of these experiments, mosquito feeding was confined to plant juices from the leaves

These results differ from those of West and Jenkins on *Aedes communis*[1] and emphasize the need for further work on the plant-feeding habits of mosquitoes

We are indebted to Dr Marshall Laird, Institute of Parasitology, McGill University, for suggesting the problem, to Dr A S West, Zoology Department, Queen's University, for help in planning the experiments and identifying the mosquitoes, and to Dr A M Moore, Biology Branch, Atomic Energy of Canada, Ltd , for identification of plants

Effects of Irradiation on the Incorporation of Amino-Acid into Normal and Regenerating Rat Liver

The biosynthesis of proteins has been studied in normal rat liver[1,2] and in regenerating liver of partially hepatectomized rats[3] Although the effect of ionizing radiations on the incorporation of amino-acids into proteins in normal rat liver has been investigated[4,5], to our knowledge it has not been investigated in regenerating rat liver The present report presents a comparison of the effects of X-rays on the potential capabilities of livers of normal and partially hepatectomized rats to incorporate amino-acids into their liver proteins in relation to the dose and time of exposure to radiation after hepatectomy

In the first of two series of experiments, 20 Sprague Dawley rats, each weighing 80–100 gm , were used Three groups, each consisting of 5 rats, were exposed to 500, 1,000, or 2,000 r of total-body X-irradiation, whereas the remaining five rats served as the non-irradiated control group In the second of these series, 20 rats, each weighing 200–250 gm , were partially hepatectomized[6] under ether anæsthesia Four groups, each consisting of four rats, were given total body exposures of 1,000 r 2, 4, 6, and 18 hr after hepatectomy, whereas the remaining hepatectomized animals served as the non-irradiated control group In both series of experiments the radiation was delivered by an X-ray tube operated at 250 kV and 15 mA. The radiation was filtered through 0 5 mm of copper and the radiation field was rendered uniform by means of a parabolic mirror, measuring in depth 14 2 cm at the centre The dose-rate was 50 r /min All rats were starved after X-irradiation, but had free access to water In the second series, food was withdrawn after hepatectomy

Each rat in the first series of experiments received an intraperitoneal injection of 3 6 × 10^6 counts per min (c p m) (3 0 μmoles) of leucine-U-^{14}C 3 hr after X-irradiation, whereas the rats in the second series received 6 0 μmoles of leucine-U-^{14}C 22 hr after operation All animals were killed 3 hr after the injection From each animal, 3 gm of liver were removed and homogenized in a Dounce all-glass homogenizer at 0° C for 3 min in 15 ml of a 0 35 *M* sucrose medium containing 0 025 *M* potassium chloride, 0 035 *M* potassium bicarbonate and 0 004 *M* magnesium chloride Each homogenate was centrifuged at 105,000*g* at 0° C for 2 hr in a preparative 'Spinco' ultracentrifuge and the clear supernatant fraction was removed and filtered through 8 layers of fine cheese cloth To 1 0 ml of the supernatant fraction 5 0 ml of 5 per cent trichloracetic acid (TCA) was added and the resulting precipitate sedimented by centrifugation was washed twice with 5 per cent TCA, alcohol and ether respectively, as described by Devi *et al*[7]. In a few instances, the precipitate was heated at 90° C. for 15 min in 5 per cent TCA, then washed and counted as before The isotope concentration of the precipitate was not changed by this manipulation Radioactivity was determined with a windowless gas-flow counter using aluminium planchets 12 5 mm in diameter on to which an infinitely thin layer (less than 5 mgm) of the aforementioned precipitate had been placed The counting error did not exceed 3 per cent

Table 1 INCORPORATION OF LEUCINE-U-^{14}C INTO LIVER PROTEINS OF NORMAL AND PARTIALLY HEPATECTOMIZED IRRADIATED RATS

Experimental series	Radiation dose (r)	Time of X-irradiation after hepatectomy (hr)	^{14}C activity (c p m /mgm of protein)	
			Range of values	Mean of values ± *S E*
Non-hepatectomized rats (Series I)	0	—	400–600	510 ± 37
	500	—	460–650	570 ± 36
	1,000	—	500–700	606 ± 39
	2,000	—	550–800	680 ± 46
Hepatectomized rats (Series II)	1,000	2	600–780	702 ± 30
	1,000	4	640–760	708 ± 22
	1,000	6	650–710	686 ± 14
	1,000	18	790–1,050	938 ± 44
	0	—	860–1,120	1,018 ± 45

The results of both series of experiments are summarized in Table 1. Evidently the intact rat liver differs qualitatively from the hepatic tissue remaining after partial hepatectomy in so far as the effect of X-irradiation on the incorporation of leucine-U-^{14}C into liver proteins is concerned Thus X-irradiation at 1,000 or 2,000 r is followed by an increase in the isotope concentration in the proteins of the non-hepatectomized rat liver, whereas in the case of regenerating liver exposed to 1,000 r a decrease in the isotope concentration in liver proteins is found if the animals are irradiated within 6 hr after hepatectomy After this time period, the exposure of the hepatectomized rats to X-rays is without effect on amino-acid incorporation The time period after hepatectomy during which the partially hepatectomized liver exhibits evidence of radiosensitivity is probably not characterized by a change in cell number since it precedes that period during which the DNA concentration increases, a pre-requisite condition for an increased rate of mitosis[8] It is conceivable that during the first 6 hr after hepatectomy conditions exist which either limit the supply of amino-acid-activating enzymes or of enzymes required for transfer of the activated amino-acids to microsomal ribonucleic acid and protein Either condition would reduce the rate of utilization of amino-acids for protein synthesis In interpreting the significance of the observed changes in the hepatectomized, X-irradiated liver, it must be remembered that there are several uncontrolled variables in the experimental conditions prevailing here for example, the variation in elapsed time between X-irradiation and the injection of ^{14}C-leucine, and the effect of starvation on the irradiated as compared with that on the non-irradiated rat livers The contribution of these factors is probably small compared with that of the X-irradiation

In the non-hepatectomized rat, radiation-induced changes are limited to the 1,000 r and 2,000 r dose-level, at the dose-level of 500 r the increase is not statistically significant Although the mechanism underlying the increased incorporation of carbon-14 into the proteins of normal livers of the irradiated animals remains unknown, two possible factors may be operating (*a*), a contraction of the leucine pool may occur, thus reducing the isotope dilution of the injected labelled leucine, and/or (*b*), a translocation of ^{14}C-labelled protein from radiosensitive sites to the less sensitive hepatic tissue[9]

In conclusion it may be stated that the normal rat liver, with cells in the inter-mitotic phase, and regenerating liver, many cells of which are in the pre-mitotic phase, seem to respond differently to the action of ionizing radiation in so far as their ability to incorporate ^{14}C-labelled leucine into protein is concerned

We thank Mr K I Altman for his interest in this work and for his many helpful suggestions

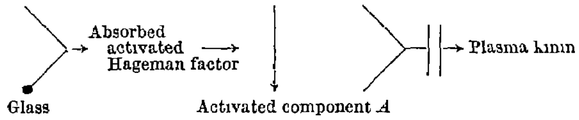
HÆMATOLOGY

Role of Hageman Factor in the Activation of Vasodilator Activity in Human Plasma

HAGEMAN factor is a clot-producing substance which is not found in the plasma of patients with Hageman trait[1] The coagulation of blood obtained from patients with Hageman trait is grossly abnormal, although hæmostasis is usually unimpaired The defect in blood in Hageman trait may be corrected *in vitro* by the addition of partially purified Hageman factor[1,2] Margolis[3,4] has shown that Hageman factor is required for the appearance in glass-treated human plasma of a permeability factor and of a pain-producing and smooth muscle-contracting substance believed to be a plasma kinin Three separate stages have been proposed for the release of plasma kinin when plasma was treated with glass



In this scheme Margolis[3] has suggested that activated component *A* and the permeability factor are the same substance Since the permeability factor and the glass-activated proteinase (activated component *A*) have not been distinguished clearly from plasma kallikrein[5], work was undertaken to determine whether Hageman factor might be related to the activation of plasma kallikrein Conceivably, component *A* might be identified with kallikreinogen, which on activation becomes plasma kallikrein In turn, plasma kallikrein could act through component *B* to release kallidin from kallidinogen[6]

Citrated plasma from patients deficient in Hageman factor and plasma from normal individuals were prepared in silicone-coated tubes and kept frozen until used 'Celite' activation was accomplished by the addition of 1–2 mgm 'Celite Filter-cel' (Johns Manville)/ml of plasma and gentle agitation for 10 min at 25°, acetone activation was accomplished by the addition of 0 25 ml of acetone/ml of plasma and by standing at 25° for 4–6 hr, and trypsin activation by the addition of 1 mgm crystalline trypsin/ml of plasma and by standing at 25° for 15–20 min [7] The vasodilator activity in the preparations, a measure of kallikrein activity, was determined by measuring the increase in blood-flow following their injection into dogs[5] The results in Table 1, recorded in Frey units of human plasma kallikrein, are averages of two or more determinations The vasodilator activity obtained by all methods of activation was probably mediated through a proteinase, since the addition of soybean trypsin inhibitor after activation prevented the increase in blood-flow

'Celite' induces clot-promoting activity in plasma containing Hageman factor but lacks this effect in plasma deficient in this substance[8] In these experiments, 'Celite' released small quantities of vasodilator activity from normal plasma With plasma deficient in Hageman factor, no activation occurred Similarly, vasodilator activity did not appear in Hageman factor-deficient plasma treated with acetone, a technique thought to destroy inhibitors and thus permit the activation of kallikreinogen by kallikreinogenase Trypsin activation, on the other hand, is thought to attack the kallikreinogen molecule directly This method liberated vasodilator activity both in normal and in Hageman factor-deficient plasma The addition of partially purified Hageman factor[9] to the Hageman factor-deficient plasma gave it the ability to produce vasodilator activity upon treatment with 'Celite' or acetone The preparation of Hageman factor contained approximately 1 5 times as much Hageman factor as that found in 1 ml of plasma and was deficient in other recognized clotting factors and in plasminogen, from which Hageman factor is readily separable[1,10,11] Higher concentrations of activated Hageman factor than those used in this work were capable of producing vasodilator activity in dogs presumably by activation of the dogs' plasma kallikrein However the results varied from one dog to another when compared with the response obtained with human plasma kallikrein and did not appear to give the same dose-response relationship

Table 1 EFFECT OF HAGEMAN FACTOR ON THE RELEASE OF VASODILATOR ACTIVITY IN HUMAN PLASMA

Method of activation	Frey units of plasma kallikrein activated in Normal plasma	Hageman plasma	Hageman plasma + Hageman factor*
None	<0 03	<0 03	<0 03
'Celite'	0 13	<0 03	0 5
Acetone	6 1	<0 6	9 3
Trypsin	10 7	5 4	—

All results calculated per ml of starting plasma

* Partially purified Hageman factor gave no detectable vasodilator activity with acetone activation, and <0 15 Frey unit of activity with 'Celite' activation

These experiments are compatible with the hypothesis that the plasma of patients with Hageman trait is not deficient in kallikreinogen but lacks either kallikreinogenase itself or some prior enzymic step required for its activation by acetone or 'Celite' Whether the vasodilator activity released from human plasma by the various methods of activation is due to the release of a single proteinase cannot as yet be unequivocally stated However, plasmin, because of its relatively low potency in producing vasodilatation[5], cannot be one of the proteinases involved Similarly, the question of the identity of plasma kallikrein with the permeability factor and the glass-activated proteinase in human plasma cannot as yet be resolved The results provide evidence that a common mechanism is involved in their release, but this does not exclude the possibility that the enzymes themselves may be different Certainly, however, the simplest hypothesis would be that they were the same substance Keele[11] has reported that salivary and urinary kallikrein form kallidin in the absence of component *B* and in the presence of soybean trypsin inhibitor It would be of interest to know whether plasma kallikrein, which is inhibited by soybean trypsin inhibitor, produces kallidin by a process dependent on component *B*

Presence of Two Iron-Transport Proteins in Serum

THE iron-binding protein transferrin was isolated in crystalline state as early as 1952, and it has been generally accepted that this was the only iron-containing protein in serum under normal conditions

Using electrophoresis in starch supporting medium according to Kunkel and Slater[1] and iron-59 determinations after electro-plating, it is possible to detect minor variations in the electrophoretic pattern which are not in agreement with this point of view The experiments were performed on human beings and the results are given in Table 1

When serum and ^{59}Fe are incubated for 15 min and investigated by electrophoresis, 11 7 per cent of the ^{59}Fe is found in front of the transferrin containing β-globulin It must be noted that no activity is found in the γ-globulin

Table 1. PERCENTAGE OF TOTAL ^{59}FE ACTIVITY

	Sample	Albumin – α_1-Globulin	α_2-Globulin	β-Globulin	γ-Globulin
	In vitro				
1	serum + ^{59}Fe	6 0	5 7	88 2	0 1
	In vivo				
2	Serum + ^{59}Fe injected	2 6	3 3	94 1	0 0
3*a*	Serum + ^{59}Fe injected 15 min after injection	5 5	1 3	93 2	0 0
3*b*	25 min after injection	3 0	1 8	95 2	0 0
4*a*	Transferrin + ^{59}Fe 15 min. after injection	10 0	7	81 3	1 5
4*b*	25 min after injection	9 4	6 4	82 0	2 2
5*a*	^{131}I-transferrin Rabbit	0 1	0 6	84 8	14 5
5*b*	Human	0 2	0 0	97 2	2 6

When serum from a patient is incubated with ^{59}Fe and re-injected, the serum from the patient shows the same type of pattern It is of interest to note that two samples taken after an interval of 10 min show the same relative distribution although the activity has decreased by 25 per cent from the first to the second sample

If the ^{59}Fe is incubated with transferrin (Behringwerke) we find again the same pattern with a splitting of the ^{59}Fe into more than one protein fraction.

The electrophoretic findings are in many ways identical with the effect of a protein–protein interaction This could, however, be shown not to be the case If iodine-131-labelled transferrin is injected into a rabbit or in a man, ^{131}I is found only at the expected place for transferrin and not where the fast fraction of the ^{59}Fe was found

The results can therefore only be taken to indicate that serum contains a protein which is not identical with transferrin and which has the ability to bind ^{59}Fe reversibly

The constant relative size of the fast fraction in experiments 4*a* and *b*, where the iron was injected bound to transferrin, makes it probable that this smaller fraction may even represent an intermediary stage between transferrin and the erythroblasts

The presence of such an intermediate in serum has been suggested by the work of Najean, Ardaillou and Bernard[2] They showed that the rate of iron transfer from transferrin to reticulocytes could be augmented by adding serum to the system The active component was non-dialysable and thermolabile

In the ghosts of erythrocytes from animals injected with ^{59}Fe Falbe-Hansen and Lothe[3] found an iron-containing fraction which could not be identified with known iron proteins This fraction appeared to be an intermediate stage in iron transport as it could only be found during the first hours after the ^{59}Fe injection. The possibility of identity between these two fractions is being investigated

Genetical Evidence for Synthesis of Transferrin in the Fœtus

Clear-cut evidence that the fœtus synthesizes its own plasma proteins is scant It has been demonstrated by *in vitro* experiments that the liver of a fœtus of three months gestation can incorporate glycine labelled with carbon-14 into proteins resembling albumin, α_1-globulin, α_2-globulin, and β-globulin of human plasma[1] These investigations also showed that metal-binding β-globulin (presumably transferrin) was capable of being synthesized by fœtal liver Other workers have established that the fœtus synthesizes haptoglobin by finding some new-born children with types of haptoglobin that were absent in their mothers[2,3]

In the course of a survey of 212 cord blood sera by starch-gel electrophoresis, genetical evidence was obtained indicating that the fœtus produces its own transferrin

The sera, each with sufficient hæmoglobin added to saturate the haptoglobin completely, were tested by Smithies's technique of starch-gel electrophoresis[4], using Poulik's discontinuous buffer system[5] The resultant gels were sliced horizontally, one half stained with amido black 10*B* to identify protein bands, and the other half with a dilute benzidine stain to locate the haptoglobin–hæmoglobin complexes[6]

Three of the 212 cord sera contained two protein bands in the transferrin region The faster migrating of these two bands corresponded to the usual transferrin designated as *C* In each case, the mobility of the slower-migrating band was identical to that of the D_1 transferrin of a reference standard These three new-born children were therefore of the heterozygous transferrin type C/D_1 The remaining 209 cord blood sera contained only one band in the transferrin region, which had the mobility of *C* transferrin These new-borns were considered to be homozygous (*Tr C/C*) Two of the *Tr* C/D_1 new-born children were negroes, while the third was of Caucasian ancestry Other examples of slow-migrating transferrins (which as a group are designated '*D*' transferrins) have been found in negro populations and Australian aborigines[6]. The three mothers of the *Tr* C/D_1 new-born children had the usual, homozygous transferrin type (*Tr C/C*), while their husbands were all heterozygous (*Tr* C/D_1) (Fig 1) In one of the negro families and in the Caucasian family, autoradiography with iron-59 performed[7] on fresh sera of the infants and their parents verified that the presumptive transferrin bands were truly iron-binding Since each of the three mothers lacked the D_1 transferrin, it is evident that transplacental passage from mother to fœtus could not account for the D_1 transferrin in the cord blood, and consequently these new-born children must have synthesized the D_1 transferrin themselves.

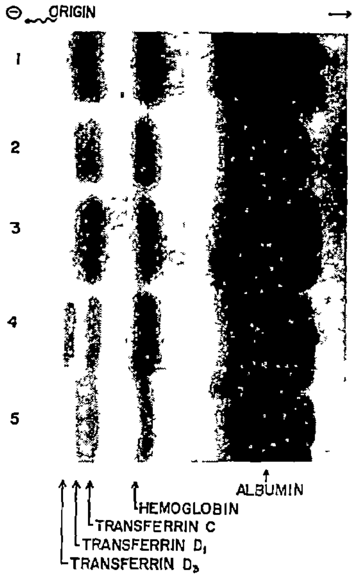

Fig 1 Portion of starch-gel electrophoretic patterns of family with new-born of *Tr* C/D_1 pattern, run in parallel with reference standards 1, New-born, *Tr* C/D_1, 2, reference standard, *Tr* C/D_1, 3, mother, *Tr C/C*, 4, reference standard, *Tr* C/D_3, 5, father, *Tr* C/D_1

We thank Dr Eloise Giblett, of Seattle, Washington, for supplying us with *Tr* C/D_1 and *Tr* C/D_3 reference standard sera This work was supported by grants from the John A Hartford Foundation, Inc , and the National Heart Institute (*H*–4706)

IMMUNOLOGY

Rapid Preparation of Fluorescent Antibodies using Gel-Filtration

In the preparation of fluorescent antibodies the excess dye is generally removed by dialysis for 5–6 days (ref 1) In order to avoid a time-consuming dialysis and to decrease the risk of destroying antibody activity we have used gel-filtration[2] in the preparation of a number of fluorescent antibodies, the titres of which were afterwards compared with those of dialysed samples A preliminary report of the method has already been published[3]

After the conjugation of serum or a serum fraction with fluorescein isothiocyanate (Sylvana Chemical Co , Orange, New Jersey) as described by Riggs *et al*[4], one portion was dialysed for six days at 2° C against a saline-phosphate buffer (0 15 *M* sodium chloride in 0 01 *M* phosphate, *p*H 7 0) with two daily changes, and another portion was subjected to gel-filtration One ml of fluorescein-treated material was put on a 2 × 5 cm column of gel-filter substance 'Sephadex *G*–25' (AB Pharmacia, Uppsala, Sweden), previously washed with the saline-phosphate buffer During elution, which was performed with the same buffer, two yellow zones appeared The fast-moving one contained the conjugated proteins, while the unbound dye was retarded partly by the gel-filtering effect and partly by adsorption to the 'Sephadex'. The strongly coloured protein fraction was collected and used for the subsequent comparison with the material prepared by dialysis Generally, a two-fold dilution

Table 1 EFFECT ON ANTIBODY ACTIVITY OF DIALYSIS AND GEL-FILTRATION

Experiment No			Antibody titres (dilution × observed titre)			
			Original serum or serum fraction	Fluorescein-labelled material		
				Without further treatment	Gel-filtered fraction	Dialysed fraction
1	Anti-*A* in pooled group *O* serum	I	1 48	1 48	1 48	
		II	1 16	1 12	1 12	1 12
2	Separated 19 *S* anti-*A*	I	1 128	1 80	1 72	
		II	1 128	1 80	1 72	1 80
3*a*	7 *S* anti-*D*	I	1 128	1 160	1 160	
		II	1 256	1 80	1 80	1 20
3*b*	7 *S* anti-*D*	III	1 128	1 20	1 36	No detectable activity
4	Rabbit anti-human γ-globulin	I	1 3200	1 2000	1 2000	
		II	1 6400	1 8000	1 8000	1 4000

I, Titrated immediately after gel filtration, II, titrated after preparation of the dialysed fraction, III, titrated two days after completion of the dialysis

Anti-*A* activity was determined using a 2 per cent suspension of type A_1 red cells in saline In experiment 1 cells from different donors were used in I and II, which precludes direct comparison between the two series In the other experiments I and II were titrated under similar conditions using fresh cells from the same donors

Anti-*D* activity was titrated using a 3 per cent suspension of papainized group *O D*-positive red cells in saline

Antiglobulin activity was determined on slides using a 5 per cent suspension in saline of four times washed group *O D*-positive red cells previously incubated with the anti-*D* serum used in experiment 3

The dilution compared with the original serum or serum fraction was 1 2 5 for the fluorescein-labelled material without further treatment and for the dialysed fraction, and 1 4 5–1 6 25 for the gel-filtered fraction

occurred during the passage through the column and, as expected, the *p*H of the alkaline protein solution changed from 9 0 to 7 0 The elution was usually completed in 10–15 min Antibody titres were determined immediately after gel-filtration as well as after storage for 6 days at 2° C -4° C , when the dialysed samples were also titrated For comparison, on both occasions the original serum or serum fraction was titrated as well as the fluorescein-labelled material without removal of excess dye

The following antibodies were investigated

(1), Anti-*A* in pooled serum from three group *O* donors (2), Anti-*A* separated from pooled human sera by starch-block electrophoresis[5] The anti-*A* active fraction behaved as a 19 *S* γ-globulin in density gradient ultracentrifugation[6] and on diethylaminoethyl-cellulose (DEAE)[7] (3*a*) and (3*b*), Anti-*D* of the incomplete type in the serum from an Rh-immunized woman The antibody behaved as a 7 *S* γ-globulin in ultracentrifugation and on DEAE-cellulose (4), Rabbit anti-human γ-globulin No 72 from Behringwerke A G , Marburg, Germany (5), Neutralizing antibody against chicken erythroleukæmia virus (CEV) Convalescent serum was obtained from a cock which had survived infection with CEV and had then been further inoculated subcutaneously four times with CEV at intervals of about one month The serum was collected 48 hr after the last CEV dose had been given The globulin fraction used was precipitated by adding ammonium sulphate to half saturation

The results of the titrations are presented in Table 1, which shows that no significant loss of activity was caused by the coupling with fluorescein isothiocyanate Nor did any significant changes in titre occur during the later removal of excess dye by either gel-filtration or dialysis in the experiments with anti-*A* (1 and 2) or anti-human γ-globulin (4) Anti-*D* (3 *a* and *b*), however, was less stable, and some loss of activity occurred during storage of the fluorescein-treated material Compared with the fluorescein-treated starting material the gel-filtered preparation showed no significant decrease in titre, whereas the dialysed fraction had a lower activity

In the experiments with CEV antibody, blood smears from a chicken with erythroleukæmia were fixed with methanol for 10 min , stained for 30 min with the fluorescent antibody solutions to be compared, and washed with saline-phosphate buffer With this procedure the stem-cells (erythroblasts) showed a specific fluorescence in the cytoplasm, whereas other cells belonging to the red cell series were not stained No qualitative difference was observed between the dialysed and the gel-filtered preparations The staining properties of various other gel-filtered conjugates containing other antibodies, as well as other fluorescent dyes, have been qualitatively equal to those prepared by dialysis

In a separate semi-quantitative experiment, fixed blood smears were stained with serial two-fold dilutions of CEV antibody, half of each slide being stained with a gel-filtered and the other half with a dialysed antibody solution of equal titre The highest dilution at which fluorescence could still be seen was 1 64 for both preparations

Thus it can be concluded that gel-filtration is superior to dialysis in the preparation of fluorescent antibodies mainly because of its extreme rapidity and also, to some extent, because it involves less risk of damage to labile antibodies

This work was supported by grants from the Swedish Medical Research Council and the Swedish Cancer Society.

BIOLOGY

Fluctuations in Hormone Activity in Brachyura Larvæ

ALTHOUGH similarities between the control of some chromatophores in larval and adult Crustacea have been noted[1], relatively little is known of the presence of chromatophorotropic substances or their development in larval Brachyura The three zoeal stages and one megalops stage of *Sesarma reticulatum*, reared from hatching to the first crab and beyond, in controlled laboratory conditions, provide an excellent source of material to test for the presence of a *Uca* black-dispersing substance in all stages of larval development and to determine if the activity of this substance during larval development is associated with the larval moult and inter-moult periods

Eye-stalks were dissected from ten zoeæ at the following intervals first zoeæ immediately after hatching, and thereafter at 12-hr intervals up to 72 hr , second zoeæ 6 hr after moulting, 18 hr , 30 hr , 42 hr , 54 hr and 65 hr , third zoeæ 2 hr after moulting, 13 hr , 25 hr , 37 hr , 44 hr and 55 hr , megalops 12 hr after moulting, 24 hr and 48 hr The eye-stalks were placed in a glass dish, the excess water removed with filter paper, and the tissues homogenized with a ground glass rod The homogenate was then diluted in 0 5 ml of filtered sea water which was boiled and centrifuged The supernatant fluid was injected into 10 adult *Uca* from which both eye-stalks had been removed 12–14 hr previously Each adult *Uca* received 0 05 ml of the extract Using the chromatophore index in which the number 5 indicates complete dispersal of the *Uca* black chromatophores and 1 signifies complete contraction[2] the chromatophore stage of the adult crabs was determined at intervals of 15, 30, 45, 60, 90, 120 and 150 min after injection The sums of the activities during the total period of dispersion[3] for the intervals noted previously were then compared to determine if fluctuations in hormone activity of the tracts were associated with a physiological state within the moulting cycle of the larvæ

To compare possible differences in technique between successive experiments, eye-stalk extract from adult *Uca* (10 pairs/2 25 ml) was injected into a separate series of 10 de-stalked *Uca* at the same time as the larval eye-stalks were assayed Sea water controls, 0 05 ml per adult *Uca*, were used with each experiment Initially, muscle from the abdominal segments of the larvæ was injected into a third series of test *Uca* Larvæ in each experiment were taken from one egg-mass to avoid possible genetic differences and eliminate variations in size of the larvæ Where possible, injections were made during the same period of the day in order to avoid diurnal differences in the sensitivity of the black chromatophore response of the recipient *Uca*

The *Uca* black-dispersing substance was found in the unstalked eyes of the first zoeal stage and in the eyestalks of all remaining larval stages of *S reticulatum* Dispersal of the black chromatophores of test *Uca* was not observed following injection of abdominal muscle from the larvæ

At the time of hatching the total activity of the hormone was lowest During the next 36 hr the activity increased, but was again reduced at the interval preceding the first moult The activity increased during the inter-moult period, was reduced prior to, and following, the second moult, and increased again during the intermoult period of the third zoeal stage This same pattern, lower activity before and after moulting followed by an increase in total activity, was observed for extracts of eye-stalks of the megalops Zoeæ which were delayed in moulting normally showed a decrease in total activity at the time when moulting would be expected but, if ecdysis did not follow, the total activity of the hormone increased again

The observed fluctuations in total activity of the hormone cannot be attributed solely to size of the moulting zoeæ since the main reduction in activity occurred prior to moulting, in other words, without any change in size The differences do not show any association with changes in light or phases of the tide It is conceivable, therefore that the fluctuations in activity are associated with moulting or the physiological processes which precede and follow moulting Although the eye-stalk of the adult Brachyura is known to contain the major site of production of the moult-inhibiting hormone it has not been established when these organs develop functionally or if they control moulting in the larval stages Even if different hormones are responsible for the control of colour changes and the control of moulting, several hypotheses are possible on the basis of these results (1), the *Uca* black-dispersing substance located within the eye-stalks of the larvæ fluctuates because of changes in titre associated with moulting but is not directly responsible for, nor involved in, the actual moulting process, or (2), if the endocrine organs within the eye-stalks of the larval stages are responsible for production or storage of several hormones, including the moult-inhibiting hormone, the reduction of the titre of the *Uca* black-dispersing substance may reflect the reduction in titre of the moult-inhibiting hormone also

The reduced titre is followed by ecdysis, a subsequent increase in concentration of the moult-inhibiting hormone, and another larval intermoult period This pattern of decreasing activity or titre prior to moulting and increasing activity after moulting would be repeated through all larval moults and carried over into the crab stages

Axenic Cultivation of an Enchytraeid Annelid

THE monoxenic cultivation of *Enchytraeus fragmentosus* Bell, 1959[1] (that is, the rearing, through successive generations in serial subculture, of this micro-annelid in the company of one[2,3] other species —in this case, *Escherichia coli*), was reported by us here[4] some months ago At that time our next goal was its axenic cultivation (that is, growth and reproduction, generation after generation, in complete isolation from living organisms—or parts thereof—belonging to other species[2,3]) We can now report success over a period exceeding 2 months at this date, with indications that such cultivation can be sustained indefinitely

After our earlier report[4], *E fragmentosus* has continued to grow monoxenically with little difficulty and is now in its sixth set of serial cultures For our first axenic cultures we used a few of the numerous worms in an old (231-day) monoxenic culture originating with one of the 3 fragments into which the initially monoxenized organism had divided[4]

Axenization was accomplished by rinsing the worms 3 times in sterile distilled water, followed by their transfer to 10 ml antibiotic solution (1,000 units potassium penicillin *G* and 100 γ streptomycin sulphate per ml), after 1 5 hr the worms were moved to a second antibiotic rinse, and, 50 min later, 7 were inoculated on to 1 5 per cent nutrient agar slants in 16-mm test-tubes, one worm per tube, the following day, 20 hr later, 5 active worms (2 had died) were transferred to individual test-tubes containing the experimental medium None of the 7 transiently occupied nutrient-agar slants developed bacterial colonies

The experimental medium was initially biphasic (1), a semi-solid base of 1 5 per cent nutrient agar, autoclaved in test-tubes 16 mm wide, allowed to cool to 48° C, and then, while still liquid, supplemented with a sterile heated (lamb) liver extract (HLE), prepared, according to a strict recipe[5] of relatively mild heating (53° C for 6 min), from liver homogenized with equal parts (w/v) distilled water The HLE was incorporated to give a 16 × dilution, uniform dispersal being achieved by gentle shaking of each tube before the agar hardened as a slant (2), A liquid phase of much smaller volume—HLE (diluted × 16), added later at 0 1 ml /tube After inoculation with antibiotic-treated worms, the experimental tubes were kept almost horizontal until evaporation left negligible free liquid—then, on the 32nd day, they were placed upright

Of the 5 tubes one showed contamination with *E coli* on the third day, one gave no visible evidence of contamination until the 32nd day (with an unidentified organism—not *E coli*—of undetermined origin), and the remaining 3, by all evidence to date, received, and continue to harbour, axenized worms In 2 of these 3 tubes the isolated worms grew to large size and began to fragment on the 36th day, yielding, within 1–2 days, 8 and 9 pieces, respectively Sub-cultures into the same medium were made on the 39th day with 5 of the offspring from one tube, one piece of worm/new tube Other sub-cultures have been initiated since Most F_1 pieces, whether left in the original tubes or sub-cultured, have recently reached adult size, and, so far, 3 worms of the former group and 1 of the latter have fragmented, the earliest, in an original tube, starting during the 29th day following the onset of first generation reproduction F_2 worms are growing, and further F_1 fragmentation appears imminent

To our knowledge, *Enchytraeus fragmentosus* is the first axenically grown annelid, being of further special interest as the only metazoon of extensive regenerative powers to be so maintained through successive generations Methods for such axenic culture of a few arthropods (insects, with the exception of one micro-crustacean) and nematodes have been known for from several to many years[3], and of a rotifer for a few months[5] HLE has now proved useful in work with members of three major invertebrate taxa *Caenorhabditis briggsae*[3] (class Nematoda, phylum Aschelminthes), *Lecane inermis*[5] (class Rotifera, phylum Aschelminthes), and *E fragmentosus* (class Oligochaeta, phylum Nematoda) For the axenic maintenance of the second and third of these, HLE has so far been a crucial ingredient in all media The preparation used for *E fragmentosus* was sterilized by Seitz-filtration, which, curiously enough, has consistently yielded HLE's inadequate for the rotifer, *L inermis* (the latter growing only with HLE filtered through 'Millipore' membranes)

With *E fragmentosus* under axenic cultivation on a complex organic (oligidic[2,3]) medium one may now reasonably set out to determine this annelid's absolute nutritional requirements

We thank the National Science Foundation for partial support, through grants *G*–6018, *G*–13138 and *G*–15034

The technical assistance of D JoAnne Ferral, Larry G Harris and Douglas L Getchell is gratefully acknowledged

Note added in proof *E fragmentosus* is now in its tenth set of serial cultures In certain tubes some or all worms show tumorous growth So far this phenomenon has been observed only when enchytraeids have been trapped in liquid—as when an excess of moisture collects, or is introduced[6], as a meniscus at the base of the slant, or when a worm is transferred into water or HLE (3 days is the shortest time so far observed with slants, 2 days with water)

Life-cycle of an Acanthocephalan Parasite of the Eider Duck

ABOUT 190 species of Acanthocephala occur in birds, but the life-histories are known only in five species In all known cases the life-cycle is indirect

Thom and Garden[1] reported an outbreak of disease among eider ducks caused by acanthocephalan parasites, and Harrison[2] also found them in eider ducks in Orkney Rayski[3] analysed the systematic position of these Acanthocephala and suggested that they are *Profilicollis botulus* (syn *Polymorphus botulus*) In the Ythan estuary, these parasites are known to be responsible for a seasonal epidemic with high mortality every year, this is also known to occur in the Dutch island of Vlieland (Van den Broek, personal communication)

In 1960, 98 dead eiders (*Somateria mollissima* (L)) were collected in the Ythan estuary, 48 of which were unfit for examination Of the 50 dissected, all except two were found to be infected with 100–750 specimens of *P botulus* This suggests that the intermediate host must be common in the locality of the habitat of the duck and must constitute a large proportion of the diet of the eider

Samples of a wide range of the food of the eider taken from the Ythan estuary (which is brackish) were examined but with no positive result The material examined was as follows *Hydrobia ulvae, Littorina littorea, Retusa alba, Mytilus edulis, Corophium volutator, Crangon vulgaris, Gammarus zaddachi-salinus, G zaddachi-oceanicus, Marinogammarus marinus* and *Cancer pagurus*

Petrochenko[4], in his monograph on Acanthocephala, quotes a paper by Belopolskaya in which she states that the intermediate host of *P botulus* is *Gammarus locusta* We therefore concentrated on searching for these larvæ in a large number of different species of *Gammarus* from the habitat frequented by eiders, but with no success For several months attempts were made to infect gammarids obtained from the south coast of the Firth of Forth near Edinburgh Collecting areas were chosen which were not known to be frequented by eiders Laboratory-bred gammarids were also used in these experiments Gammarids greedily devoured both eggs and worms containing eggs They did not become infested, though in some cases eggs were seen in the alimentary canal several days later, hatching had not taken place

Eventually, a single specimen of the common shore crab *Carcinus moenas* was collected and fed with a worm containing a large number of eggs of *P botulus* Two days later the crab was dissected and about a dozen acanthors were seen in process of hatching in the alimentary canal Eventually 10 crabs collected from the same area were fed with eggs and worms containing eggs Five crabs died in the space of 3–5 weeks after infection and were found to contain large numbers of developing acanthellæ One crab died 50 days after infection, showing a large number of acanthella stages Four crabs were killed and examined 62 days after infection and two of these contained fully developed cysts containing acanthellæ (cystacanths) and two others had a large number of acanthellæ

From these experiments it was clear that the crabs had been hyper-infected, and at the same time it was obvious that full development of *P botulus* takes place in *C moenas*

Since then, 68 shore crabs from the Ythan estuary have been examined, and 29 of them were found to be infested with cysts containing acanthellæ of *P botulus*, the numbers varying from 1 to 9 in each crab When these were examined microscopically and the proboscis of the larvæ was compared with the proboscis of adults, it was found that number, arrangement and shape of hooks were identical The cystocanths were situated in the region immediately under the heart, and either above the hind gut or on both sides of it The very high rate of infestation in the shore crab in the Ythan estuary explains the common occurrence of this acanthocephalan parasite in eider duck

This is the first record of the crab *Carcinus moenas* acting as intermediate host in the life-history of acanthocephalan parasites

Unfortunately, Belopolskaya's paper is not available to us, and we have been unable to find out on what grounds she concluded that the larvæ found in *G locusta* were really the early stages of *P botulus*

ENTOMOLOGY

Intracellular *Rickettsia*-like Micro-organisms in Certain Ticks

Little attention has been paid to the intracellular *Rickettsia*-like micro-organisms in acarines Perhaps the first approach to a comprehensive survey on these organisms in ticks was that of Cowdry[1], although a few earlier observations were made[2-4] Cowdry reported the occurrence of intracellular micro-organisms, of rickettsial nature, in the malpighian tubules and in eggs of several species of ixodid and argasid ticks He pointed out that, being present in eggs and unfed larvæ, the organisms were transmitted by inheritance, and postulated a symbiotic function Further work on the morphological appearances of such micro-organisms and their distribution in the malpighian tubules and oocytes of some of these tick species were developed by Buchner[5], Mudrow[6] and Jaschke[7]

Of the several species of *Argas*[8], however, it appears that only *A persicus* has been shown to possess intracellular *Rickettsia*-like micro-organisms Recent work[9] describes in detail for this tick the nature and distribution of the organisms in the malpighian tubules and in its oocytes at different stages of development, their recognition and description being based on histochemical methods and electron microscopy

Suitor and Weiss[10] also recently reported mainly serological and cultural aspects of this organism, isolated from the malpighian tubules, but not, it appeared, from the oocytes, and proposed from their description the name *Wolbachia persica* S and W

The present communication reports on intracellular micro-organisms of similar rickettsial appearance in the ticks *Argas vespertilionis*, *A transgariepinus*, and *A boueti*, collected from bat-infested places in the Abu-Rawash area near Cairo, Egypt In these ticks, as in *A persicus*, the organisms are found in almost all cells of the malpighian tubules and in oocytes In the malpighian tubule cells, the organisms are mostly present in groups of variable size, though single coccoid and short rod forms have been seen

In the oocyte cytoplasm, the organisms appeared in smaller groups, and were only demonstrable after combined ribonuclease enzyme treatment and Giemsa staining[9] or after Feulgen–Schiff's technique

Further work on the nature of the organisms in these species of *Argas*, including examination by electron microscopy is in progress, the work includes a survey also of representatives of other tick genera

I wish to thank Prof D S Bertram, director of this Department, for his valuable suggestions and helpful guidance in the work

Biological Species confused under the Name *Culicoides austeni* (Carter, Ingram and McFie)

The age-grading techniques at present widely used in the study of biting Diptera having been found applicable to *Culicoides* in Gambia, they were used systematically with material referred to *C austeni* (Carter, Ingram and McFie) As a result it became apparent that material referable on morphological grounds to this species showed pronounced biological differences correlated with differences in its larval habitat Hopkins[2] and Nicholas[3] reared this species from rotting banana litter and Gambian material from this habitat agreed with theirs in requiring blood-meals throughout life for maturation It never mated under laboratory conditions and field observations showed that mating normally occurred in crepuscular swarms Far more abundant in Gambia, however, was a form of this species which, while morphologically identical, differed in having its larval habitat in the salt-water mangrove swamps of the river estuary. The salt-water form proved to be autogenous in the first ovarian cycle, maturing its first batch of eggs at the expense of the larval fat body without taking a blood-meal Swarming was never observed in this species and was evidently not obligatory since it mated freely without it under laboratory conditions, even as a single pair in a glass vial

Since *C austeni* s str was described from a coastal area (Accra, Ghana) the possibility of its being the salt-water form is quite strong The soil-breeding form, presumably that studied by the Nigerian workers and implicated in transmission of filariasis, was synonymized with *C milnei* Austen by Nicholas *et al*[4] *C milnei*, however, also occurs in Gambia and is clearly distinct from both forms of *C austeni* lat in having fully separated eyes as stated by Carter *et al*[1] in their original description of *C austeni*

Salt-water *C austeni* exhibits a pronounced 14-day periodicity due to synchronization of emergence with spring tides As a result of this, the age composition of the population varies cyclically, primiparæ biting for the first time, predominating at times of peak density and higher age groups at times of low density Correlated with this rhythm, a marked decrease in survival-rate after the third oviposition was apparent when the dissection results were substituted into the total numbers The immature stages have not been reared through from egg to adult, but enough is known to make it clear that the life-cycle cannot be completed between one spring tide and the next With a hatching time of two days, a fourth instar larval life of 4–5 days and a pupal life of 3 days the probability is that it can be completed in two full tidal cycles Taken together, these two factors imply the existence of two populations, ovipositing and emerging in alternate spring-tide periods, between which a considerable degree of isolation exists

Also breeding in the mangrove swamps is a third species of the group which can be separated morphologically from the two forms referred to above by virtue of its marked melanism This form, which is certainly a taxonomically separate species, is considered to be very much more closely related to salt-water *C austeni* than either is to the soil breeding form Like salt-water *C austeni* it is autogenous in the first ovarian cycle, mates without swarming and also comprises two alternating populations The two salt-water forms breed in different parts of the mangrove swamp, salt-water *C austeni* in the areas dominated by *Avicennia nitida* and the related species in parts of the zones characterized by *Rhizophora racemosa* and *R mangle* The peaks of emergence exhibited by these two species are usually out of phase with each other by several days, presumably in association with the different soil-levels and times of inundation of their respective habitats

For the taxonomy of this material I am indebted to Dr W W Wirth of the United States National Museum, Washington, D C The advice is gratefully acknowledged of Dr I A McGregor, director of the Medical Research Council Laboratories in Gambia, with whose permission these results are published

Sorghum Midge, *Contarinia sorghicola* (Coq.), in West Africa

BARNES[1] listed the dates of the first definite records of the sorghum midge, *Contarinia sorghicola* (Coq), in various African countries as Sudan (1930), Nyasaland (1950), Uganda (1951), Aden Protectorate, Gambia, Kenya and Tanganyika (1952), Nigeria (1953) He suggested that these records probably reflect the fact that only in recent years have economic entomologists in Africa been able to turn their attention from cash crops to food crops, and that the midge was well established in these territories before it was first reported

In 1958 Matthee and Oberholzer[2] reported the first appearance of the midge in South Africa and supported the alternative explanation of these records, namely, that the midge was introduced into Africa from America and has gradually spread southwards from the Sudan

In an attempt to determine whether or not the midge was introduced to, and is spreading through, the African continent, we have begun an investigation of herbarium material of the genus *Sorghum* collected in Africa during the past century Herbarium specimens are examined for symptoms of midge damage, and, where this is suspected, spikelets are removed for dissection under the microscope Cecidomyiid larvæ and pupæ have been dissected from material collected more than thirty years ago, and, although larvæ and young pupæ cannot be identified beyond their genus, specific determinations can be made on the adult characters which are displayed by fully developed pupæ

A preliminary survey of the West African section of the genus *Sorghum* in the Kew Herbarium has revealed a wealth of material from which the following new records of *C sorghicola* have been made (Table 1)

Table 1 NEW RECORDS OF *Contarinia sorghicola* (COQ) IN WEST AFRICA

Country	Locality	Host	Date of collection of host
Northern Nigeria	Zaria	*S guineense*	1929
	Munchi	*S guineense*	1929
	Sokoto	*S caudatum*	1929
Gold Coast	Northern Territories	*S guineense*	1931
	—	*S guineense*	1930

In addition, larvæ of the genus *Contarinia*, which are almost certainly *C sorghicola*, were obtained from *S margaritiferum* collected in Sierra Leone (Port Lokko) in 1929

The oldest *Sorghum* collections, made in 1859, yielded no specimens of midge, possibly because these collections are less representative, and in poorer condition than the more extensive collections made in the 1920's and 1930's It is therefore impossible, at this stage, to determine whether the midge has or has not been introduced to Africa, since the new records presented here will easily fit into a pattern of initial introduction to West Africa, followed by distribution eastwards to the Sudan and then southwards to South Africa

However, it is obvious that Barnes was correct in suggesting that the sorghum midge might have been overlooked by economic entomologists in Africa

Effect of Age and Pregnancy on the Tolerance of Tsetse Flies to Insecticides

It has been found that, in the laboratory, old female *Glossina morsitans* Westw show a considerably greater tolerance to some chlorinated hydrocarbon insecticides than do the young flies of both sexes, and in particular that pregnant flies show an exceptional degree of tolerance Complete log-dosage/probit-mortality regression lines have been determined for dieldrin (Table 1)

Dieldrin was applied in solution in lighting kerosene as a constant volume (0 022 µl) to the mesothorax of flies which had emerged from wild pupæ and had been given a blood feed the previous day Pregnant flies were defined somewhat arbitrarily as those more than 50 mgm in weight at the time of testing, and fertilized flies were those less than 50 mgm in weight and more than 21 days old They were a mixture of those insects which were in an early state of pregnancy or had recently larviposited or aborted All lines were parallel, and all differences given in Table 1 are significant at $P = 0$ 05 (ref 1) Old females also show significantly increased tolerance to DDT and γ-BHC, but males do not develop tolerance as they age These tests have been extended to *G swynnertoni* Aust caught as wild adults, and pregnant females were found to be nine times as tolerant as males to DDT

That breeding females are up to nine times as tolerant as young flies is of obvious practical significance In a recent paper, Yeo and Simpson[2] have given a theoretical forecast of the final results to be expected from repeated applications of a non-residual insecticide to wild tsetse populations, basing their calculations on a constant kill attained at each application The kill is usually assessed from catches of males, and for the first one or two applications, of females They discuss the results of a number of experiments in aerial control The apparent kill for both sexes is normally more than 90 per cent, that for males being the higher, but the final reduction at the end of the experiment is frequently consistent with a kill of about 60 per cent[2] It is suggested that this is because the major part of the measured mortality falls on young flies, the old breeding females escaping These form a small proportion of catches because the mean life of wild females is only 1–2 months[3] and because they come most readily to man when young[4] Thus a high kill may be recorded without any great reduction in the breeding population This will, of course, fall as the old flies die from natural hazards, but the result will be to delay the expected reduction in breeding and increase the value of the later applications above that assigned by Yeo and Simpson's analysis It is also necessary to re-examine the conclusion that an inter-treatment interval close to the pupal period is the best At the appropriate season in Central Tanganyika, the mean temperature is about 24° C [5], the pupal period about 31 days and the mean age at deposition of the first larva 23 days[6] Thus by the end of the third week of life the female fly is pregnant and tolerant of insecticide This means that, with an inter-application interval of 4 weeks[2], all females emerging in the week after an application are potentially tolerant of the next

A second consideration concerns tests for insecticidal resistance For these, care must be taken to test only males or females of known age

Increase in Distribution of *Deraeocoris olivaceus*

The study of animal introductions and their fate provides an object lesson in ecology[1] Some, as the leafhopper *Graphocephala coccinea*, become permanent elements of the British fauna, others, as the tingid *Stephanitis rhododendri*, achieve an initial spread but later contract, still others, such as the rhopalid *Liorhyssus hyalinus*, can do no more than maintain an occasional very temporary colony in Britain The present communication concerns a conspicuous mirid bug, *Deraeocoris olivaceus*, which it is timely to map after a space of ten years It occurs on *Crataegus* (hawthorn), usually becomes adult during July, and is collected by beating, its biology is known in broad outline[2]

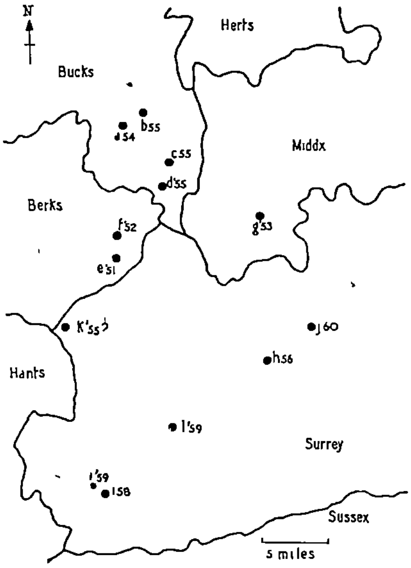

Fig 1 Distribution of *Deraeocoris olivaceus* (Hemiptera, Miridae) in southern England, showing year of first capture at each locality For names of localities see text

The bug was found for the first time in Britain in July 1951 at Silwood Park, Sunninghill, Berks, by Sands[3] It is known in Europe from Greece and the Balkans to France and the Low Countries but is absent from the Baltic lands and Scandinavia Fig 1 shows known occurrences with the year of first capture, based on published[4] or unpublished[5] records The localities, all in Berks, Bucks, Middx or Surrey, are (*a*) Burnham Beeches, (*b*) Hedgerley Park, (*c*) Langley Park, (*d*) Ditton Park, (*e*) Silwood Park, (*f*) Windsor Forest, (*g*) Hounslow Heath, (*h*) Bookham Common, (*i*) Witley and Elstead Commons, (*j*) Epsom Common, (*k*) Camberley, (*l*) Shalford Many of these localities are well known to collectors, and it is unlikely that the bug would be overlooked for more than a year or two

During the past few years the Herts–Middx and Hants–Surrey borders have been searched for the insect but so far without a capture in either Herts or Hants It seems, therefore, that Fig 1 represents the present distribution, based on records during the decade 1951–60, fairly accurately Recent checks have shown that the bug is still present at its earlier known stations Spread of the insect from its 1951–55 area is thus shown to have been slight, save towards the south where its advance seems to be on a broadening front The host-plant is common throughout southern England, so any restraint imposed on it is likely to be climatic No braconid parasitism has so far been detected although its congeners in Britain are known to be attacked

MICROBIOLOGY

New Method of preparing *Corynebacterium pyogenes* Toxoid with High Anti-hæmolysin Titre in Rabbits

Corynebacterium pyogenes is generally grown in Robertson's medium[1] when small quantities are prepared and in derivatives of this medium for vaccine production Producing this medium for vaccines is an expensive time-consuming operation, so it was decided to investigate the possibilities of using fat-free milk as the basic medium Strains used throughout the work were those recently isolated from bovine lesions and used at present for vaccine production

To a 10-l 'Pyrex' bottle was added 7 l of fresh skimmed milk with a natural *p*H of 6 8, this being particularly important since milk with a higher acidity was found to coagulate on autoclaving The *p*H was raised to 7 4 using 40 per cent caustic soda To this was added 100 gm of calcium carbonate for controlling acidity during incubation Stoppered with cotton wool, the bottle was autoclaved at 5 lb /sq in for 30 min At a higher temperature caramelization of the lactose was found to occur resulting in a dark filtrate After cooling to 37° C the medium was inoculated with 10 ml of a 48 hr active unwashed culture of *Corynebacterium pyogenes* grown in Robertson s medium, with a hæmolysin titre of 1 640 A sterile rubber stopper fitted with an air filter and a length of glass tubing which almost reached to the bottom of the bottle replaced the cotton wool During the 48-hr incubation period at 37° C sterile air was passed slowly through the medium, carbon dioxide was also tried without equal success, as a cloudy filtrate resulted After 24 hr coagulation and digestion of the casein had begun, and after 48 hr all that remained was a small floccular precipitate and pale-yellow supernatant, colourless in small quantities The resultant supernatant was clarified afterwards through kieselguhr and sterile-filtered through Berkfield candles, there was very little loss of fluid during filtering The hæmolysin titre obtained by this method was 1 1,000 The filtrate was toxoided by the addition of 0 5 per cent formalin and this was incubated at 37° C over a period of 2 days 0 5 ml was injected intravenously into two mice which showed no toxic reaction after 24 hr The *p*H was then altered from 5 8 to 6 8 using 40 per cent caustic soda, and 'Thiomersalate' (British Drug Houses) in the final dilution of 1 10,000 was used as preservative 'Thiomersalate' was used in preference to phenol or tricresol as the latter preservatives tended to precipitate the proteins, causing an opacity in the toxoid which increased in density with time and high storage temperatures

Rabbits used in this work were tested for natural immunity before inoculation and those possessing antibodies were not used Their sera were titrated against 5 and 10 minimal hæmolytic dose of *Corynebacterium pyogenes* toxin Ten rabbits were injected with 10 ml of the toxoid intramuscularly with another injection of 15 ml ten days later and 20 ml 10 days after that The animals developed no signs of shock after injection nor was any rise in temperature noted, thus proving that milk pyrogens had been destroyed The animals were bled 14 days after the last injection On titrating the rabbit sera against 10 minimal hæmolytic dose of *Corynebacterium pyogenes* toxin 0 00156 ml of sera inhibited hæmolytic activity, controls were set up This figure represents thirty-two times the potency standard for *Corynebacterium pyogenes* set down by the British Veterinary Codex After 2 months of retesting, the sera showed no appreciable drop in titre I feel this method could be extended to other aerobic and anaerobic proteolytic organisms used for production of vaccine

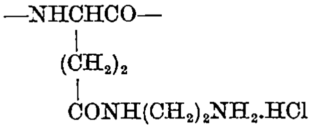
Antibacterial Synthetic Polypeptide Derivatives

As already stated[1], some synthetic polypeptide derivatives exhibit considerable antitubercular activity These antibacterial polypeptide derivatives were prepared from poly-α-aminodicarboxylic-acid-esters (for example, polymethyl-α-poly-L-glutamate, polymethyl-α-poly-DL-aminoadipate) and from polyaminodicarboxylic-acid-anhydrides (for example, anhydro-poly-aspartic-acid) with diamines (ethylenediamine, β-dialkylethylenediamines)[2]

The hydrochloride of the polypeptide derivative which was prepared from polymethyl-α-poly-L-glutamate with ethylenediamine, in particular, was examined, and is now produced by Chinoin Chemical and Pharmaceutical Works Co , Budapest, for clinical experiments under the name of 'Polyanthin' The characteristic feature of the structure of 'Polyanthin' can be given in the formula below, the unit represented is the main component of the polymeric material



$$\begin{array}{l}\text{—NHCHCO—}\\ \quad\ \ |\\ \quad (CH_2)_2\\ \quad\ \ |\\ \quad CONH(CH_2)_2NH_2.HCl\end{array}$$

The microbiological activity of 'Polyanthin' against different micro-organisms was further examined The examinations, the results of which are summarized in Table 1, were performed as follows the strains given in Table 1, were inoculated in bouillon media and incubated at 37° C for 24 hr With 0 1 ml quantities of these cultures, bouillon media containing various amounts of 'Polyanthin' (see first column of Table 1) were infected The controls were infected media with no 'Polyanthin' and non-infected culture media with 'Polyanthin' The degree of growth of the micro-organisms characterized by crosses in Table 1 was visually evaluated after incubation at 37° C for 24 hr

As seen in Table 1, 5–20 γ/ml of 'Polyanthin' restrains the growth of *Staphylococcus aureus haemolyticus* (Wood), and also of the penicillin- and sulphamide-resistant variations of *Staphylococcus aureus haemolyticus* isolated from diseased persons, of *Bacillus subtilis, Mycobacterium friburgensis* and *Mycobacterium smegmatis* There was no effect against bacteria belonging to the Gram-negative group, like *Proteus vulgaris* and *Escherichia coli*, even in concentrations as high as 300 γ/ml 'Polyanthin' seems to be active above all against those strains to which glutamine is necessary for the initiation of growth[3]

After the favourable results of the preliminary investigations clinical tests of 'Polyanthin' were also carried out 'Polyanthin' was used, so far only for local treatments, particularly in obstetrics and gynæcology, as well as prophylactically and in cases of developed suppurations It was used in obstetrics for the treatment of episiotomies and injuries of the vagina and cervix, in gynæcology after different operations of the vagina and abdomen in cases where the healing of the wound was disturbed

A solution, containing 1·3 gm 'Polyanthin' in a litre of water, was used for the different treatments either in the form of rinsings or for the soaking of gauze strips applied as tampons and covers The controls are similar cases as those treated later with 'Polyanthin', but taken from the time before the testing of 'Polyanthin' had begun These control cases were treated with wound powders ('Ultraseptyl-urea' (Chinoin Chemical and Pharmaceutical Works Co , Budapest), 'Dermaphorin' (United Works of Pharmaceutical and Dietetic Products, Budapest)) and wound ointments containing cod-liver oil

From Table 2 it is seen that when 'Polyanthin' is used for the treatments the primary healing of

Table 1

Nature of Colicine Receptors

Colicines are unique among antibiotics in being specifically adsorbed on to the surface of bacteria in a manner analogous to antibodies and bacteriophages Besides being removed from solution by adsorption on sensitive bacteria[1], they can be inactivated by extracts of sensitive, but not of resistant, organisms[2] The nature of colicine receptors on the bacterial surface has not so far been elucidated This communication describes some preliminary observations on the subject

Absorption experiments were undertaken, using two of Fredericq's strains, namely *Shigella sonne P*9, producing colicine *S*3, and the colicine-sensitive *Escherichia coli C*6 When colicine was mixed with preparations of the sensitive *E coli*, each killed by a different procedure, then centrifuged and the residual colicine assayed, a number of properties of the receptor sites were demonstrated They were unaffected when the organisms were killed by heat at 65° C for 30 min , by exposure to 0 3 per cent formalin or 2 per cent phenol, but were destroyed by heating at 100° C for 1 hr or exposure to 80 per cent ethanol

The residual colicine was titrated by the agar diffusion technique developed by E van Horn (personal communication) By this technique small differences in colicine titre can be detected, and results may also be obtained with a more than hundred-fold dilution of the original colicine Partial absorption of colicine could thus be detected but, in fact, in the absorption experiments described here either all or none of the colicine was removed from the solution

The results obtained with the absorption experiments were corroborated by assaying the colicine on agar plates inoculated with a mixture of viable and killed organisms The inoculum consisted of 5–10 × 10^6/ml viable organisms of the sensitive *E coli*, mixed with a suspension of 5–10 × 10^8/ml organisms of the same *E coli* killed by the methods used in the absorption experiments The killed suspensions in which the receptor site had been destroyed did not materially alter the size of the inhibition zones, those in which the receptor sites were intact adsorbed colicine and hence the inhibition zones were significantly reduced in size The amount of reduction was comparable with that obtained by an inoculum of viable cells, substituted for the killed organisms[3]

From these observations it appears that the receptor, at least for this particular colicine, resembles most closely a flagellar or, to a lesser extent, a fimbrial antigen *E coli C*6 is non-motile, which lends particular interest to the finding of a receptor substance on its surface having the properties of a flagellar antigen

MISCELLANEOUS

A Simple Flattener for holding Filter Papers on Planchettes for Radioactive Counting

The use of a 'Millipore' chimney and filter paper provides a convenient means of collecting radioactive material for measurement of its activity A major disadvantage of this system arises from the curling of these papers by the precipitated materials and the allied difficulties of fitting them in the planchette The use of doubly gummed 'Scotch' tape provides only a partial solution to this problem, and if the material on the filter paper is to be analysed chemically afterwards, the tape adhesive may interfere The use of liquid adhesives and, in the case of 'Millipore' filters, of solvents also does not solve this problem The amount of collected material is limited by the point at which the precipitate will flake and not hold to the paper Recently we devised a simple spring mechanism to hold the paper in the carriers

The precipitates are collected on the surface of hardened small-pore filter paper (for example, Whatman No 42) or modified cellulose papers ('Millipore' filters) and dried in a desiccator The flatness of the resulting material is a function of the amount of precipitated material collected The diameters of the papers are slightly smaller than the inside diameter of the planchettes used (Nuclear-Chicago sample pan 1¼-in in diameter) The papers are fixed inside the planchette by use of a 330° arc of stainless steel spring wire No 24 gauge, so made that the arc has a diameter ¼ in greater than the planchette (Fig 1) The wire is placed within the planchette and on the paper by compressing it with the thumb and forefinger and placing the closed end against the wall of the planchette The spring is then permitted to expand slowly below the level of the planchette side wall, and final adjustment is made with a pair of forceps

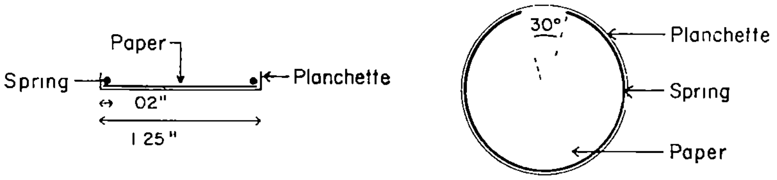

Fig 1 Details of arrangement of the spring flattener

We have found these uniquely successful in holding the papers and their contents flat, they are simple to use and easy to clean They will withstand brief washing in dichromate cleaning solution, may be autoclaved, and can be made by most machine shops A convenient material, though not stainless steel, is commercially available piano wire Thicker wire will provide additional strength where required

Chemico-Linguistics: Computer Translation of Chemical Nomenclature

I WISH to report what is believed to be the first successful mechanical translation of chemical names into chemical formulæ Tsukermann and Terentiev[1] have indicated their intention to work on this problem

Programming the initial experiments was simplified by imposing several restrictions Simulated tests by manual methods have been successfully performed without these restrictions (*a*) longest carbon chains allowed are ten carbon atoms in length, (*b*) maximum length of chemical names is 59 characters, (*c*) elements other than carbon, hydrogen, oxygen, nitrogen, sulphur, bromine, chlorine, fluorine and iodine were eliminated

The most significant aspect of this research is the linguistic study of chemical nomenclature which preceded, for several years, the development of the computer programme[2]

In effect, a recognition grammar for organic chemistry has been written which can be used not only for mechanical indexing but also for teaching chemical nomenclature Using Harris's methods[3,4] for grammatical analyses both the morphology and syntax of chemical nomenclature were analysed Morphemes, allomorphs, homonyms, etc , were identified as well as their roles in the generation of molecular formulæ

The difficult problem of calculating hydrogen values was overcome by application of the following formula, which is a modification of Soffer's[5] formula for determining double bonds and cyclic structures

$$H = 2(\Sigma M_C - \Sigma M_{db} + 1) + \Sigma M_N - \Sigma M_X$$

where M_i is an expression indicating the summation of the computational values represented by morpheme class i For example, M_C is the number of carbon atoms implied by all morphemes in the chemical names which contain carbon This completely resolved the tedious, though solvable, problem of constructing more complex rules for hydrogen calculation which are required when one attempts to follow the 'natural' inclination to record methyl as CH_3, amino as NH_2, etc

It is the ultimate objective of this work to generate accurate molecular formulæ for all chemical names and also to display and print ideographs, that is, structural diagrams Once the initial linguistic problems have been completely resolved, this can be done It has already been shown that computers can be instructed to draw such diagrams[6,7] However, neither Opler nor Waldo began with uncoded chemical names It is one thing to programme a computer to draw a diagram for a known specific chemical In this case, a human coder works from a diagram drawn by someone and calculates a cipher that is used by the computer to draw the same diagram It is another matter to translate, without human intervention, from chemical names to structural diagrams

The most difficult problem one encounters when trying to include all methods of naming chemicals, rather than just systematic International Union of Pure and Applied Chemistry names, is the ambiguity of different ring-numbering systems While this does not affect the ability to calculate molecular formulæ, it does affect the ease of creating entirely accurate diagrams In such cases the computer will render an invaluable service in reminding the chemist that several alternatives must be considered It may also remind authors to stipulate whether they are following International Union of Pure and Applied Chemistry or some other system

From a linguistic point of view, it is an interesting observation that the basic language of all naming systems in organic chemistry is essentially the same While two chemists will name the same compound differently, both will be able to draw the same structural diagram In this sense, the use of different systems corresponds to the problem of handling dialects rather than treatment of separate distinct languages In addition, the complete understanding of the mechanisms for translating the language of organic chemistry provides useful experimental data for the more general problem of mechanical translation If we cannot solve the problem of translating chemical nomenclature, there would seem to be little hope for translating natural languages such as English with a machine

The following chemical compounds (Table 1) illustrate the capabilities of the present computer programme While a *Univac* I was used for this experiment, the programme can be modified without too much difficulty for smaller computers such as the I B M 650 (ref 8)

Table 1

Chemical name	Molecular formula
1,4-*bis*[*bis*(3-Diethylaminopropyl)amino]butane	$C_{32}H_{72}N_6$
2-[(2-Aminopropyl)ethylamino]ethanol	$C_7H_{18}N_2O$
8-Hydroxy-6-octene-2,4-diynenitrile	C_8H_5NO
1,3,3,4,4-Pentachloro-2-methyl*cyclo*butene	$C_5H_3Cl_5$
2-Phenyl-2,4,6-*cyclo*heptatriene-1-one	$C_{13}H_{10}O$
7-(2,4,5-Trichlorophenoxy)heptanoic acid	$C_{13}H_{15}Cl_3O_3$
Ethyl 2-cyano-5-phenyl-2,4-pentadienoate	$C_{14}H_{13}NO_2$
2-Naphthyl-2-*cyclo*hexen-1-one	$C_{16}H_{14}O$
Diphenyl-3-butynol	$C_{16}H_{14}O$

I wish to thank Dr J O'Connor and Mr C Meunch for their help in writing this programme, Dr C Borkowski for fruitful discussions on problems of mechanical translation, and Prof N Rubin, who acted as my chemical 'informant'.

INSTITUTE OF INFORMATION SCIENTISTS (at the Swedenborg Society Hall, 20 Bloomsbury Way, London, W C 1), at 6 15 p m—Sir Lindor Brown, F R S Presidential Address

INSTITUTE OF WOOD SCIENCE (at Carpenters Hall, Throgmorton Avenue London, E C 2), at 7 p m—Mr P O Reece "The Establishment of Safety Factors and Stresses for Timber".

OIL AND COLOUR CHEMISTS' ASSOCIATION (at Manson House, 26 Portland Place, London, W 1), at 7 p m—Dr L M Baraken "Solvents in the Surface Coatings Industry"

SOCIETY FOR ANALYTICAL CHEMISTRY BIOLOGICAL METHODS GROUP (at the Chemical Society Burlington House, Piccadilly, London, W 1), at 7 p m—Miss Maureen Wilson "The Use of Bacteriophages in Epidemiology"

Thursday, October 19

UNIVERSITY COLLEGE, LONDON (in the Anatomy Theatre, Gower Street, London, W C 1), at 1 15 p m—Dr M Mary Douglas "Cult and Ordeal as Techniques of Sorcery Control in the Belgian Congo" *

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p m—Discussion of a paper by Mr J T M Taylor on "Mining Practice on the Kolar Gold Field, India"

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W 1), at 5 p m—Scientific papers by Dr Anna B Hastings and Dr H G Vevers

UNIVERSITY OF LONDON (at Westfield College, Kidderpore Avenue, London, N W 3), at 5 15 p m—Mrs Grace Wyndham Goldie "Television in Society" *

LONDON PLANETARIUM (in collaboration with the ROYAL SOCIETY and the ROYAL ASTRONOMICAL SOCIETY, at the London Planetarium, Marylebone Road, London, N W 1), at 5 30 p m—Dr Joseph Needham, F R S "Astronomy in Classical China"

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m—Prof A S Parkes, F R S "External Factors in Mammalian Reproduction" * (Second of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

SOCIETY OF INSTRUMENT TECHNOLOGY (at the Royal Institution Albemarle Street, London, W 1), at 6 p m—Sir George Thomson, F R S "The Inspiration of Science" (First Thomson Lecture)

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the SOUTH-EAST ESSEX TECHNICAL COLLEGE SCIENTIFIC SOCIETY, at the South-East Essex Technical College, Longbridge Road, Dagenham, Essex), at 7 p m—Dr S I Levy "Chemical Patents"

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W 1), at 7 30 p m—Scientific Papers

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W 1), at 8 p m—Ordinary Meeting followed by Mr F G Spear "Questioning the Answers" (Presidential Address).

UNIVERSITY OF LONDON (in Swanley Hall, Withersdane, Wye College, near Ashford Kent), at 8 15 p m—Prof J D Bernal, F R S "Science in History".

Thursday, October 19—Friday, October 20

INSTITUTION OF CHEMICAL ENGINEERS, GRADUATES AND STUDENTS SECTION (at the Royal Overseas League, St James's, London, S W 1)—Symposium on "Scale-up and Pilot Plants"

Friday, October 20

BRITISH PSYCHOLOGICAL SOCIETY, OCCUPATIONAL PSYCHOLOGY SECTION (in the Department of Psychology, Birkbeck College, Malet Street, London, W C 1), at 1 p m—Dr R A M Gregson "Operational Research, Psychological Information and Managerial Decisions"

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W 1), at 5 30 p m—Mr T A Brock "Petroleum Products in Cosmetics".

Saturday, October 21

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m—Mr E Milne-Redhead "A Plant-Collecting Expedition to Southern Tanganyika" *

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

SCIENTIFIC OFFICER (male, with a good honours degree), for genetical, physiological and breeding research with cereals—The Secretary, Plant Breeding Institute, Trumpington, Cambridge (October 21)

MAP CURATOR/LIBRARIAN (preferably with qualifications in geography and librarianship) IN THE DEPARTMENT OF GEOGRAPHY—The Registrar, The University, Sheffield (October 23)

RESEARCH PHYSICIST, Senior Scientific Officer (with an honours degree together with several years appropriate experience) at the Defence Standards Laboratories, Finsbury, near Adelaide, South Australia, for basic studies relating to the effects of light, X- and gamma-radiation on photoconductive materials and the physics of electrophotography—The Senior Representative (AV 125/6), Department of Supply, Australia House, Strand, London, W C 2 (October 26)

ASSISTANT LECTURER IN PURE MATHEMATICS—The Registrar, The University, Nottingham (October 28)

LECTURER or DEMONSTRATOR (Assistant Lecturer) IN PHYSIOLOGY—The Registrar, The University, Leeds 2 (October 31)

LECTURER or ASSISTANT LECTURER IN BIOCHEMISTRY—The Registrar, The University, Sheffield (November 4)

JUNIOR RESEARCH FELLOW (with a good first degree in zoology) IN LOCUST PHYSIOLOGY IN THE DEPARTMENT OF ZOOLOGY, University College of Rhodesia and Nyasaland, for work on the water relations of locusts—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 8)

READER IN CHEMICAL PATHOLOGY at the Postgraduate Medical School of London—The Academic Registrar, University of London, Senate House, London, W C 1 (November 8)

LECTURER IN PHILOSOPHY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, November 15)

LECTURER (with special interest in plant physiology or morphology or taxonomy) IN THE DEPARTMENT OF BOTANY, University of Ghana—The Assistant Registrar (London), University of Ghana, 15 Gordon Square, London, W C 1 (November 15)

LECTURER/SENIOR LECTURER IN ORGANIC CHEMISTRY at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall London, S W 1 (Australia and London, November 17)

LECTURER (with a good honours degree and experience in research or teaching, and preferably qualifications in the history and philosophy of science) IN THE SCHOOL OF PHILOSOPHY, University of New South Wales—The Agent-General for New South Wales, 56 Strand, London, W C 2, and the Appointments Section University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (November 17)

SENIOR LECTURER (with a higher degree or equivalent qualifications) and a LECTURER (with an honours degree) IN THE SCHOOL OF NUCLEAR ENGINEERING, University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and the Appointments Section, University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia November 17)

Lecturer and an Assistant Lecturer in Inorganic Chemistry—The Registrar, The University, Nottingham (November 22)

Lecturer (with an honours degree in chemistry and preferably a higher degree, and experience and a special interest in modern physical methods) in the Department of Chemistry, Newcastle University College—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and the Appointments Section, University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (November 24)

Chair of Pharmacology in the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 30)

Keeper (with an appropriate university degree, and preferably museum experience and/or a knowledge of herbarium work) of the Department of Botany—The Secretary, National Museum of Wales, Cardiff (November 30)

Lecturers (2) in Physiology, and a Lecturer in Pharmacology at Makerere University College, East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 30)

Senior Lecturer in Meteorology, and a Lecturer in Glaciology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, November 30)

Assistant Experimental Officer/Experimental Officer (with a degree or H N C in chemistry or equivalent), for work mainly concerned with the analysis of foods and feeding-stuffs of tropical origin—The Director, Tropical Products Institute (D S I R), 56 Gray's Inn Road, London, W C 1, quoting Ref YE 709/9

Assistant Lecturer, Grade B (with a good honours degree in mathematics and preferably some teaching or research experience), in Mathematics—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex

Entomologist (with a good honours degree in biology, with entomology as a special subject, and not less than two years postgraduate research experience in entomology) at the West African Institute for Trypanosomiasis Research, to carry out laboratory and field investigations on tsetse flies, at Kaduna, Northern Nigeria—The Crown Agents 4 Millbank, London, S W 1, quoting Ref M3B/53514/NF

Junior Technical Officer (with G C E at "A" level in two science subjects, one of which should be botany or biology), for work in a section investigating the cytogenetic effects of radiation—The Administrator, Radiobiological Research Unit, Medical Research Council, Harwell, Didcot, Berks

Lecturer (with a good honours degree in physics and preferably a Ph D degree, and preferably experimental research experience in some aspects of plasma physics and an interest in high-current discharge work) in the Department of Natural Philosophy—The Secretary, Royal College of Science and Technology, George Street, Glasgow, C I

Librarian (with a knowledge of chemistry or physics) in the Department of Chemical Engineering and Chemical Technology—Prof A R Ubbelohde, F R S , Imperial College of Science and Technology, London, S W 7

Postdoctoral Fellow, for research in flame spectroscopy or a related subject—Dr A G Gaydon, F R S , Chemical Engineering Department, Imperial College, London, S W 7

Postdoctoral Fellow, for research in modern concepts between structure and biological activity or organic molecules, organic synthesis and stereochemistry—Prof B Belleau, Department of Chemistry, University of Ottawa, Ottawa, Ontario, Canada

Research Assistant (Graduate), to undertake cell counts as part of an investigation on the growth of cereal seedlings—The Secretary, Agricultural Research Council Unit of Plant Physiology, Imperial College of Science and Technology, London, S W 7

Scientific Officer (male or female, with an honours degree in science, pharmacy or biology) in the Blood Transfusion Service, for duties which will consist of technical work in the Blood Transfusion Service Laboratories—The Director, Blood Transfusion Service, Roby Street, Manchester 1

Senior Laboratory Technician, Grade 1 (with appropriate qualifications and experience)—The Head Master, King Edward VI School, Southampton

Statisticians (2) (with good qualifications in mathematics and statistics) to engage in the development of biometric techniques for medical research and the application of electronic computers to medical problems—The Secretary, Marischal College, The University, Aberdeen

Technician at the Marine Biological Station, Port Erin—The Registrar, The University, Liverpool 3, quoting Ref CV/N/M B S.

THE SCIENTIST AND THE COMMUNITY

THE address, "Power and Responsibility in Science", which Prof. M. Swann broadcast in the Third Programme on the eve of the British Association for the Advancement of Science meeting at Norwich (August 29) in no way anticipated Sir Wilfrid Le Gros Clark's presidential address, though in his concluding passages Sir Wilfrid summoned scientists to play a special part in promoting opportunities for free intercourse and the free interchange of ideas among the peoples of the world. Prof. Swann is no less convinced that scientists have something to offer the world besides their discoveries, but he did not touch on this particular question of co-operation, except to note that, in simple terms of its influence on mankind, H. B. du Pont, when addressing the Franklin Institute, once described the development of the modern industrial corporation as the greatest invention of all, exceeding even the influence of the steel plough, steam locomotive, the telegraph and telephone, and the flour mill of Oliver Evans, which was the precursor of automatic control.

Prof. Swann began indeed by referring to certain discoveries of science which had reduced drudgery, transformed communication and transport and enhanced or improved the standard of living, or relieved pain and suffering, doubled our life-span and vastly improved food production. These discoveries, apart from the impact of science on ways of thought, could undoubtedly be placed on the credit side even if there were other things such as the atom bomb or the misuse of scientific ideas to bolster up racial, economic or political theories to be placed on the other side.

Prof. Swann, however, was not attempting to strike a balance but to indicate the vast power which science has come to wield over the human race. This power, he argued, is exercised without responsibility and this is one reason for the anti-scientific feelings sometimes encountered. Moreover, because every scientific discovery depends on what has gone before, such power as science exercises is not applied by individuals but collectively by scientists as a whole and all must in some sense accept responsibility. While at the individual level the concept that power and responsibility must be linked has long been established, its acceptance at the collective level of government and society is a much more recent achievement, and Prof. Swann taxes science with having evaded this issue of the responsible exercise of power which is at the heart of modern democracy.

It was not suggested by Prof. Swann that this evasion is deliberate. It arises out of the very nature of science as, first and foremost, a search for knowledge, and it was much later—Prof. Swann puts it within the past century—that knowledge came to mean power, and still more recently that the power and the attendant responsibility of science became glaringly obvious. To-day, he remarks, even a research worker in the most esoteric corner of science can no longer feel sure that he is not laying foundations for some new advance with all sorts of practical implications. The scientist who fails to develop a social conscience can no longer be excused.

Prof. Swann does not, however, analyse this question of responsibility at all deeply or even the position of the scientist in the community in which he works. He considers the question whether the scientist has anything beside his discoveries to offer the world in which practical decisions have to be made and discoveries translated into action, for good or for ill. He recognizes, of course, that under present conditions society contrives fairly effectively to prevent scientists as such from doing much to improve the situation. Prof. Swann makes the point that there is just as much need, and possibly more immediate prospect of success, for scientists to enter public life vigorously at lower levels than those of the higher reaches of government—in the councils, committees, boards of governors, through which the life of the local community is ordered. Moreover, he suggests that foresight is only a part of the scientist's whole attitude to tradition and progress and that here the scientist has something further to offer to the national way of thought.

Considering the way change occurs in public life, Prof. Swann points out that to the scientist the past is worthy of respect and represents the best that able minds could achieve. The scientist, above all men, depends on the work of those who have gone before him, and because we have the advantage of other men's labours we should be able to go further and do better. Prof. Swann looks on the scientist as a conservative and evolutionary influence in public life rather than a revolutionary influence, seeking to add to the structure, remodel it here and there, to change but not to destroy.

Closely linked with this is the stress Swann lays on the scientist's insistence on the experimental approach. This is built so firmly into science that the scientist scarcely realizes how much less instinctive it is in the outside world, and Prof. Swann frankly advocates an extension of the experimental approach, for example, in such matters as nationalization. Here, of course, he enters on the wide issues of influence, as opposed to power, and of the place of the scientific outlook and scientific method in public affairs, and these are vital aspects of the problem of the right relation of knowledge and power. Moreover, it is necessary to distinguish between the scientist as a scientist and the scientist as a citizen, for the responsibilities are not identical, and failure to distinguish between them has led to mistaken action as well as to the opposition to science which Prof Swann notes

The scientist as such has influence rather than power It is his responsibility to exercise his foresight so far as in him lies, and to point out the consequences that must follow the adoption of particular scientific or technical measures Only to that extent does he bear political responsibility as a scientist Whether, however, he is able to exercise that advisory function at a high enough level or sufficiently effectively or early is a matter for society as a whole, and it is here, as citizen, that the scientist must recognize a responsibility to work to ensure that the structure of government allows scientific and technical advice to be tendered appropriately and effectively This civic responsibility requires also that he should seek to ensure that educational policy is such that it provides for the task of administration those competent to assess scientific and technical advice and give it due weight along with other factors in a situation

It is only when scientists as citizens prove effective in the discharge of such responsibilities that one can speak of the scientists as exercising power Even if, and when, a scientist is appointed to a position of high responsibility in the executive government, it is not as a scientist but as a citizen that he holds and exercises power It is important that this should be clearly understood, for confusion over the relations between the layman and the scientist to-day is responsible for much of the opposition to the wider use of the scientific method and to the establishment of conditions in which scientific work is most effectively done It is scarcely conceivable that there will be any reversal, either in the advanced or the backward races, at the national or at the international level, of the process of applying the fruits of scientific knowledge But the real reason why this confusion over the relations between the layman and the scientist and their respective responsibilities for the use or misuse of science is dangerous was brought out rather better by Sir Solly Zuckerman in the Stephen Paget Memorial Lecture in November 1959, and in his address at the California Institute of Technology in June of that year (see *Nature*, 184, 135, 1959)

Sir Solly pointed out that there is a sense in which science is the handmaiden of the economic or social institutions in which it functions—a framework which is indeed to some extent continually being transformed by new scientific ideas and the application or practical development of those ideas, but which nevertheless to some extent determines what ideas shall be developed A material civilization of motor-cars, or jet planes, of radio and television, of man-made fibres and nuclear power is not necessarily the only form that civilization might have taken Now that it has taken that shape, Sir Solly remarked it helps to define for us the content and the boundaries of the area within which we exercise our freedom Pursuit of some major development, for example, the development of the steam engine, means that some other path that potentially might have been followed is not followed

This is as yet only imperfectly grasped in Britai to-day, though it is being strongly emphasized b such topics as space research There are, moreover two further points to be made in this context First this choice of development is not one that is made b the scientist as such It is a political choice, only t a limited extent made on scientific or technica advice, and Sir Solly Zuckerman reminded us that i may not even be conscious, and that only partly because of the unpredictability of any new majo scientific advance or the increasing complexity o scientific knowledge in the applied field It is also partly because in the application of scientific knowledge means tend to become ends, the discovery o new ways of doing things transforming the things done and so their purpose

Here Sir Solly's vision is clear, but its implications have not as yet been widely discussed or the requisite steps taken to provide some means of guarding against the dangers to which he directed attention Rejecting as too simple the idea that to-day democracy has abrogated its rights to a bureaucracy which is determining the direction we are taking, Sir Solly maintained that, since the element of the unknown in government increases with every step we are now taking to apply the fruits of science, if sovereign power is being abrogated it is less to a governing body, however formed, and more and more to a process of applying scientific knowledge without any real possibility of determining its final consequences Neither the voice of the majority nor those through whom it is expressed can proclaim the precise lines of the future

This is a vital point which Prof Swann overlooked, it is dangerous to speak of the power and responsibility of the scientist if it is not recognized that while the scientist may be the better able to appreciate the scientific aspects of a situation, he is not responsible as such for the application of the new knowledge and cannot be held responsible for predicting some vast social transformation which might result from a seemingly trivial observation Nor is it sufficient to urge the need to regard education in science as constituting an essential element in a liberal education We need above all to appreciate, as Sir Solly put it, that in the major scientific matters which now affect human destiny, we cannot safely take decisions for to-day unless we realize that those same decisions determine the future It is at this point that the scientist's foresight ought to be exerting its decisive influence, and the survival of mankind may well turn on the urgency and vision and determination which are brought to bear on the creation of the institutions which will enable the scientist to make that contribution effectively Nor is that solely a challenge to creative thinking or inventiveness It is equally a challenge to the scientist and technologist to respond to Prof Swann's appeal and use to the full, imaginatively and constructively, such opportunities of public service that may already confront them as citizens Even when new opportunities are provided, scientists and technologists will only be able to use them adequately as they gain experience of public work Perhaps one of the most constructive steps that our major scientific professional institutions could now be taking would be to stimulate the interest of their younger members in public service and to assist them to gain the experience and the outlook which would enable them to make their particular and unique contribution most effectively

HUMAN PARASITES

Animal Parasites in Man

By Dr N H Swellengrebel and M M Sterman Pp x+652 (Princeton, N J D Van Nostrand Company, Inc , London D Van Nostrand Company, Ltd , 1961) 67*s* 6*d*

It is difficult, as one reads through this book, to decide what type of reader its authors had in mind First issued sixty years ago, it has now been re-written and enlarged, and its authors hope it will be useful to the physician and the biologist For the physician seeking an introduction to this subject and information about the epidemiology and treatment of human parasitic infections it may well seem adequate, but the biologist or medical man who requires guidance and information on difficult points of detail or procedure may prefer one of the several text-books of medical parasitology which are available at not much greater cost The biologist, moreover, may wish for more systematics than this book attempts to give and more on the features of the main groups of parasites He may wonder, too, at some statements, such as the suggestion that all trematodes are flat "like a flatfish or the leaf of a tree", and why the authors have introduced into an otherwise excellent introduction such terms as "proliferous" and "non-proliferous" parasites, "initial aggressors" and the like , and at the division of the common parasites of man into the Protozoa, Metazoa and the "Scolecida, or lower worms", one wonders, too, whether Sabin would nowadays agree with the statement attributed to him in 1953 that toxoplasmosis is an "almost perfect host–parasite relationship in which the parasite only rarely causes serious damage to its hosts, and the hosts are not too intent on destroying the parasite"

Apart, however, from points like these, the text is, as one would expect from a book bearing the highly respected name of Prof N H Swellengrebel, accurate and as up to date as any book can, in these days of very rapid advances in knowledge, hope to be Among the best sections are the new chapters on methods of examination of the excreta and blood for eggs and larvæ of parasites and on the methods for the enumeration of the eggs of parasites and on serological methods of diagnosis The bibliographies at the end of each chapter will also be useful to readers who wish to extend their knowledge The book is written in an easy style and shows the host and parasite in conflict with each other, a point of view which leads the authors to use such phrases as "the host's defense mechanism was kept constantly on the alert" (p 127), or the host applies "topical" or "numerical" restraint on the parasite, phrases which are useful only if great care is taken not to mislead the reader An odd feature is the disproportionate space given to the rare occurrence of *Babesia bovis*, a parasite of cattle, in splenectomized human subjects It is true that babesiasis may be a risk to which man, and especially splenectomized man, may rarely be exposed, and the space given to this disease would be justified in a large and comprehensive text-book , but it should be accompanied by a fuller consideration of the Babesiidae than is given here It is difficult, too, to understand the statement (p 127) that "calves are the only hosts to suffer" from *Babesia bigemina*, because they suffer less severely than adult cattle and it is explained on the same page that they acquire pre-immunity It is implied, also, that *Boophilus annulatus* is the only invertebrate host of *Babesia bigemina*, whereas at least 10 ticks belonging to 3 genera have been recorded as its invertebrate hosts The tick, moreover, is here described as the intermediate host, whereas it harbours the sexual phases of the *Babesia* and is therefore the definitive host

Most of the numerous illustrations are taken from other text-books, and it is unfortunate that many have suffered much in the process of reproduction Outstanding examples are the figures of *Echinococcus granulosus* (p 267), and the black-and-white figures of the exo-erythrocytic stages of *Plasmodium inui* and *P falciparum*, which give no idea of the clarity and draughtsmanship of the originals These examples are the more regrettable because other figures are well reproduced

The format of the book and its general make-up and print are attractive, but its price, compared with that of the bigger and more detailed text-books available, is high G Lapage

CANCER OF THE RECTUM

Cancer of the Rectum

Edited by Cuthbert E Dukes (Neoplastic Disease at Various Sites, Vol 3) Pp xiii+304 (Edinburgh and London F and S Livingstone, Ltd , 1960) 50*s* net

This is the third volume of the series *Neoplastic Disease at Various Sites* under the general editorship of Prof D W Smithers In one way, at least, the volume is unique eleven of the eighteen contributors are connected with St Mark's Hospital, London—seven as consultant surgeons, two as consultant pathologists, and two as research assistants Not only are these contributors familiar with each others' views and methods, but also for many years the work of the surgeons has been co-ordinated through a single pathology department and follow-up system In this connexion the immense and universally acknowledged contribution of Dr Dukes himself is further made evident by the fact that his accurate observations, his plan for the examination of operation specimens and dissection of lymph nodes and blood vessels, his pathological classification, and his histological grading of rectal cancer, form the basis on which the contributing surgeons analyse their operative results, and are unquestionably the framework on which many of the recent advances in surgery of rectal cancer have been made

Theoretically, at least, the fact that so many of the contributors have been working in close association with each other, carries with it the danger that the views expressed here are narrowed through inbreeding. Only in Chapter 13, written by Prof J C Goligher of Leeds, is mention made of methods practised in other countries Some may be surprised to read that combined abdomino-perineal excision by two surgeons operating simultaneously is little practised in America, or in Germany and other Continental countries The views of an American or Continental surgeon, particularly with regard to the choice of operation, might well have made an interesting additional chapter As it is, the reader is left with the knowledge that the abdomino-perineal excision is the operation most commonly practised in Britain, but with the feeling that anterior resection with sphincter preservation might be the better operation for at least a proportion of cases On the other hand, one hastens to say that the descriptions of the different surgical techniques are both remarkably clear and admirably brief Each is written by a surgeon who has immense experience of the operation in question

Some of the tremendous advances in surgical technique, especially in the resectability-rate, during the past thirty years, are attributable to improved anæsthesia antibiotics, anticoagulants, a better understanding of surgical shock and its treatment, and to the consequent possibility of undertaking more radical operations Some have arisen as the direct result of pathological observations, for example, the observation that cancer of the rectum rarely spreads downwards and therefore that sphincter preservation is feasible Finally, some are undoubtedly the direct result of the concentration of surgical and nursing experience at St Mark's Hospital itself In this latter connexion this book is a poignant answer to those who still oppose the establishment of ultra-specializing treatment centres in Britain

The section (pp 36–39) by Dr Dukes on the control of rectal cancer in polyposis families provides an unparalleled example of cancer control. By keeping detailed records of polyposis families and by going to great lengths to keep in close touch with them, it has in many cases been possible to undertake colectomy before metastasizing cancer has developed At the same time an understanding of the inheritance of the disease has enabled the surgeon to relieve the minds of unaffected siblings of the fear that they too might eventually develop the disease

Surprisingly, no special space is set aside for consideration of the pre-operative general examination or preparation of patients On p 251, in the chapter on operative complications (Chapter 22), Mr Gordon Ungley writes " . a pre-operative intravenous pyelogram is of immense advantage, should serious urinary complications arise" The desirability of conducting this and other investigations pre-operatively in certain patients should surely have been discussed somewhere earlier in the volume

As regards alternatives to surgery, cancer chemotherapy is not mentioned, but radiotherapy is well dealt with by Dr Williams in Chapter 19 Here no strong claim is made for the value of radiotherapy other than as a palliative measure On the other hand, it is pointed out that only recently have X-ray voltages in excess of 1 MeV been available, these give less severe skin and mucosal reactions than lower voltage X-rays, and better results may be expected from radiotherapy in the future

The authors of the final section entitled "Possibilities for Future" (p 277) conclude that further improvement in prognosis must depend mainly on earlier diagnosis and earlier surgical treatment, but they do not suggest how these may be achieved It seems unlikely that exfoliative cytology, which is mentioned briefly on p 132, will be found to have much value as a quick screening test

One problem which urgently needs an answer i "to what extent, if any, does surgical biopsy, and the pre-operative or operative manipulation of tumour increase the risk of distant metastasis via the blood stream?" Now that appropriate and reliable methods for the detection of circulating cancer cells are becoming available, it is to be hoped that this question will soon be answered The technique called 'Chemosurgery' developed by Mohs[1] is being increasingly practised in the United States and some European countries It is likely that it would prove of value in the diagnosis and treatment of possibly malignant polyps and of lesions of the lower rectum near the anal margin

At the end of an excellent review chapter (Chapter 5) on "Tumours of the large intestine of mammals other than man", Dr Roberts discusses the experimental induction of tumours of the large gut by chemical substances The possibility that constituents of the diet, or that anal ointments or suppositories, play an ætiological role cannot, without further research, be excluded The fact that little space is given to consideration of the ætiology of human rectal cancer is a measure of the paucity of research in this field.

None of the criticisms made here is more than minor, and they detract very little from the value of the contents of the book The contributors and editors are to be congratulated on the clarity of style and presentation, on the high quality of most of the tables and illustrations, and on the remarkable degree of continuity Moreover, the choice of paper and size of type are admirable The book will be of value to a wide variety of qualified doctors whether primarily concerned with surgery or not In addition, the figures for operative mortality and 5-yr survival will provide a useful yardstick by which surgeons can measure their own prowess when using the same techniques and by which the value of new techniques can quickly be assessed **Francis J C Roe**

DEVELOPMENTS IN VETERINARY SCIENCE

Advances in Veterinary Science

Vol. 6 Edited by C A Brandly and E L Jungherr Pp xi + 382 (New York Academic Press, Inc, London Academic Press, Inc (London), Ltd, 1960) 12 dollars

THIS volume, which follows the pattern of previous ones, covers seven main subjects In the first chapter, screw-worm research and eradication are dealt with Details are given of the biology of the screw fly, its geographical distribution and the means of rearing it under laboratory conditions Chief interest in this section will probably be found in the discussion on the means of screw-worm eradication by releasing sterilized males in an infested area The genetic basis for sterilization by irradiation is discussed in a concise but thorough manner Insecticides in the form of wound dressings, sprays and dusts, including organo-phosphorus compounds, are discussed in the concluding chapters of this section

In the second chapter foot-and-mouth disease and related vesicular diseases are dealt with in considerable detail Although a number of the facts set out here are already well known, they are very wisely reiterated in order to form a correct basis for the subsequent discussion The distribution of foot-and-mouth virus types and sub-types, the ætiology, prevention, control and eradication as well as diagnosis are covered in some detail. At the present time, when the control of this disease throughout the world is receiving active attention, the information on types of vaccine and their preparation and application is of more than academic interest Vesicular stomatitis and vesicular exanthema, virus diseases which show so many clinical signs similar to those of foot-and-mouth disease, are discussed from the same angle While in Great Britain the absence of these two diseases makes the diagnosis of foot-and-mouth disease less complicated, the position in the United States is not so simple, and differentiation between the three viral diseases covered in the chapter is a practical necessity in those States in which all three could occur simultaneously

To those primarily interested in animal husbandry, the chapter dealing with the effects of nutrition on microbial disease will have a special appeal Any confusion of thought on what really constitutes disease, infection, nutrition and ecology is dispelled by the critical and clear definition of these terms with which the chapter begins The authors summarize the effects of the various food constituents on the prevention of patent disease in the animal

In summarizing their conclusions, they liken the balance between the host and micro-organism to a game of chess in which the result more commonly depends on a series of moves and counter-moves than on a single finalizing move, and point out that the micro-organism may in many cases overcome its host by the narrowest of margins

The fourth chapter deals with anaplasmosis, covering historic development, distribution and incidence, and the evolution of epizootics in the United States The epidemiology of the two main types of anaplasma and of organisms of similar type but doubtful nature, such as eperythrozoon, are given due attention Transmission of the parasite by ticks, flies and mosquitoes and transmission *in utero* and accidentally by direct contact with infected animals are discussed Investigations of the parasite, including the use of electron microscopy, problems of its reproduction, its cultivation, its properties and its pathogenesis (aided by the use of radioisotopes), occupy a considerable part of this chapter and will be found to be of fundamental importance to those interested in this protozoan blood parasite Diagnosis by clinical and laboratory means, the pathology of the disease and its prophylaxis and therapy, with a note on the future for its control, complete a full and valuable description of this widespread disease of the blood

The fifth chapter covers a great deal of ground without being unduly long It deals with the comparative pathology of arthritis and embraces the many forms of arthritis in all classes of livestock, including birds In the concluding remarks to this chapter, it is pointed out that the chemical composition of articular cartilage has not yet been studied on a comparative basis and that little is known of the character of normal synovial fluid in the various species This observation must surely suggest lines for future research

The following chapter deals with coccidioidomycosis This fungal disease, which has been found to affect both animals and man, is described from the point of view of its history, its incidence, its classification (including its saprophytic and parasitic forms) and the conversion from one form to the other With inhalation as the usual mode of infection of men and animals, the epidemiology of the disease makes an interesting study, and it is noted that certain races of humans and certain breeds of animals are more susceptible than others Pathogenesis and pathology are discussed, and diagnosis, prognosis and treatment are dealt with. The public health significance of the disease renders an investigation of it all the more important

The final chapter deals with canine distemper, a disease of which so much has been written. Here we find the more important considerations condensed into a valuable and all-embracing treatise The question is posed "Does distemper produce a long-lasting immunity because there is one serological type or, conversely, is there one serotype because the virus evokes a high-grade immunity?"

As in the case of previous volumes, this sixth volume contains a comprehensive list of references on each of the subjects discussed as well as author and subject indexes of considerable value to the reader The high standard set by previous volumes is fully maintained and another addition of outstanding value to the teacher and research worker will find its way on to their bookshelves, not to lie there but to be consulted freely and profitably.

HAROLD BURROW

THE FATTY ACIDS

Fatty Acids

Their Chemistry, Properties, Production, and Uses, Part 1 Edited by K S Markley. Second completely revised and augmented edition. (Fats and Oils a Series of Monographs on the Chemistry and Technology of Fats, Oils, and Related Subjects) Pp ix+714 (New York Interscience Publishers, Inc , London Interscience Publishers, Ltd , 1960) 169*s*

THE first edition of this work was published in 1947 as a single 668-page volume, written entirely by K S Markley The material covered has now been expanded to such an extent that this second edition occupies four parts, each with its own index Part 1 is concerned with the content of the first third of the 1947 edition and has chapters by Markley on the individual acids and isomerism (250 and 36 pages, respectively), by R T O'Connor on X-ray diffraction and polymorphism (94 pages) and spectral properties (120 pages), and by W S. Singleton on the properties of the liquid state and of solutions (111 and 70 pages, respectively)

Markley's section on the acids has more than 600 references and covers most types of aliphatic carboxylic acid—natural and synthetic, short- and long-chain, saturated and unsaturated, and oxygenated The acids are dealt with individually, the main points of discussion being occurrence, structure, preparation, applications and properties The more important acids, industrially as well as academically—such as oleic acid and the naturally occurring acetylenic acids—are treated at some length, though the approach tends to be historical and somewhat classical rather than critical The tables of physical constants and other properties are numerous and well presented Unfortunately, the literature coverage does not appear exhaustive, though it is certainly extensive

Those vital adjuncts of modern organic chemistry, the physical methods, are expertly and concisely introduced and the relevance and application of the main methods to the fatty acid field are well brought out X-ray diffraction, ultra-violet, visible, infra-red and micro-wave spectroscopy, and nuclear magnetic resonance are each discussed The estimation of *trans*-isomer content by infra-red spectroscopy and other similarly important applications are carefully documented though, again, I would have preferred a more critical appraisal of the present situation

The properties dealt with under 'the liquid state' include heats of formation and combustion, density, molar volume, viscosity, surface tension and refractivity, many of the data being economically presented in tabular form The final chapter surveys the properties of aqueous and non-aqueous solutions of the acids and their glycerides

In summary, Part 1 of this completely rewritten and enlarged edition of *Fatty Acids* provides an unrivalled survey of the field covered The complete work, which will consist of Parts 1, 2, 3 and 4, should prove a worthy successor to the first edition

GEOFFREY EGLINTON

COTTON IN INDIA

Cotton in India

A Monograph, Vol 2 By R H Dastur, R D Asana, K Sawhney, S M Sikka, R S Vasudeva, Quadiruddin Khan, V P Rao and B L Sethi Pp viii+339 (16 plates) Rs 30, 45*s*

Vol. 3 By C Nanjundayya, R L N Iyengar, W R Natu, M B Ghatge, K S Murti, C B Parikh, B L Sethi and D N Mahta Pp viii+295 (20 plates) Rs 30, 45*s*

Vol 4 By S M Sikka, Arjan Singh, Avtar Singh, P D Gadkari, R Balasubrahmanyan, N K Iyengar, K Sawhney, V K Bederker, G B Patel, P S Pandya, V N Paranjpe and N S Panigrahi Pp x+378 (20 plates) Rs 30, 45*s*

(Bombay Indian Central Cotton Committee, 1961)

THE monograph *Cotton in India*, the publication of which has been sponsored by the Indian Central Cotton Committee, is now completed by the issue of Volumes 2, 3 and 4 Volume 1 has already been reviewed in *Nature*, 189, 86 (1961)

The second volume deals with physiology, agronomy, diseases, insect and mite pests, and with seed multiplication and distribution The third volume concerns itself with technology, ginning and pressing, marketing, consumption of cotton (seed and lint), legislative measures and exports and imports The fourth and final volume treats of the special features of the six recognized cotton regions of India

As the work covers every possible aspect of cotton in India, with a large number of contributors, it is difficult to discuss any points in detail Practically all work done in India is mentioned and, though some can only be described as trivial, important findings occur sporadically throughout the work The laborious and painstaking, though somewhat unfruitful, work of Dastur on applied physiology deserves special mention He points out that no fundamental physiological research has so far been attempted as all attention has been concentrated on the physiological causes of bud and boll shedding, bad opening of bolls with immature seeds and lint, premature yellowing and reddening of leaves, low yields of seed cotton, etc The important work on cotton physiology in Trinidad by Mason and his co-workers, Maskell and Phillis, receives only scant attention In Egypt much fundamental work was done by Balls and his colleagues, much of which has some bearing on Indian problems There is a casual reference to the *Cotton Plant in Egypt* published in 1912, but later work during 1927–47 is ignored The subterranean environment, probably as important as the aerial one, does not seem to have been studied, and it is significant that 'roots' finds no place in the index

In Volume 3, several pages in the chapter on technology are devoted to an exposition of statistics at the elementary text-book level This inclusion would appear to be unnecessary The section on small-scale spinning-tests covers less than a page and is inadequate Although of great importance to India, the pioneer small-scale spinning-plant set up by Balls and Hancock in Egypt is not mentioned

The index can only be described as amateurish and calamitously inferior It is neither comprehensive nor usable, and is quite unworthy of the encyclopædic nature of the work The virtues of the monograph, however, greatly outweigh the defects, which regrettably include an undue number of printer's errors On the whole, it is a reasonably good attempt to put on record what is known about cotton in India and will undoubtedly find wide use as a standard work of reference

S C HARLAND

SOME ASPECTS OF ASIATIC RUSSIA

Physical Geography of Asiatic Russia

By S P Suslov Translated from the Russian by Noah D Gershevsky Edited by Joseph E Williams Pp xiv+594 (San Francisco and London W H Freeman and Company, 1961) 105*s*

THIS book—a large quarto, printed on good glossy paper and containing well-reproduced text, maps and diagrams as well as photographs, although these as a rule are not so well reproduced—possesses all the potentialities of a good and informative book Actually it suffers from many original and translation defects

First and foremost the book purports to be the *Physical Geography of Asiatic Russia*, but this title does not accurately describe the contents of the book Physical geography must clearly include geomorphology and structural geology In these fields the book is very weak, whereas the sections on hydrography, soils, plants and animals are adequate and well presented The names of plants and animals are translated into vernacular English and their Latin names are printed in brackets Their habit and ecology are well described—the general impression being that the writer is a specialist in bio-geography, not physical geography On the other hand, the geomorphological and geological sections are written in a casual and often inexpert manner, occupy a small proportion of the text, are often disposed throughout the text and are inadequately illustrated by geological maps and sections This is particularly annoying since great progress has been made during the past hundred years in the study of the geology and geomorphology of the Asian part of Russia, as evidenced by the work of such authorities as Obruchev, Shatsky and Nalivkin

Returning to the title, we read *Physical Geography of Asiatic Russia* Here it must be pointed out that the frontiers of Asia with Europe follow the Urals watershed, the Ural River and the watershed of the Great Caucasus Chain In the book the eastern Uralian region and the Transcaucasian region are excluded This means that in the first part of this book, entitled "Western Siberia", which comprises the greater part of the River Ob', all the headwaters of its left tributaries and all the important mining and metallurgical zone of the Uralian region are excluded The exclusion of Transcaucasia means also the exclusion of a very important part of the Alpine orogenic belt, stretching from the Carpathians to the Hindu Kush

The first three parts of this book deal with Siberia, while the fourth and last part deals with central Asia The territorial division is done in a very peculiar manner, which agrees neither with the leading geological nor with the geographical features The first part, entitled "Western Siberia", embraces the western Siberian lowlands, Altai, Salair and the Kuznetsk basin So far, so good One would expect then that Part 2 would deal with central Siberia, but its title is "Eastern Siberia", and the title of its first chapter (Chapter 4) is also "Eastern Siberia", while the title of its Chapter 6 is "Central Siberia" For a century, the plateau region situated between the Rivers Yenisey and Lena has borne the name of "Siberian Platform", as it is characterized by a unity of geological-tectonic structure and a unity of morphological features Now, according to the authors, the northern part of the "Siberian Platform" receives the name of "Eastern Siberia" and the southern part "Central Siberia" Under" Eastern Siberia" are also included Sayan, Tuva, Cis- and Trans-Baikal regions—mountainous regions most properly linked with Altai–Salair–Kuznetsk basin Again, Part 3, entitled "Far East", is made to embrace Amour and Maritime Province, which is the true Far East, as well as Sea of Okhotsk coastal region and the Kamchatka-Kurile region, the two western provinces which, in spite of their situation, are not generally called the "Far East" Part 4 deals with central Asia, which is plausibly divided into semi-desert, desert and mountain regions

The results of this peculiar regional planning are obvious Geologically and geomorphologically Altai, Salair, Kusnetsk, Sayan and Tuva represent a definite structural-tectonic unit, which, in this book, is broken up into various disjointed chapters The balance struck between the geological–morphological and other aspects is illustrated by a typical chapter on the Altai in which, out of 45 pages, 19 are devoted to bio-geography, 6 to geology and 8½ to morphology In other chapters, such as Chapter 4, dealing with part of the central Siberian Platform, there is no section on geology In Chapter 5, dealing with the Arctic, the most important geological structure of Taimyr is not described at all The book has only one proper geological map (Kuznetsk basin) in addition to a tectonic map of the Transbaikal region and a few maps of Kamchatka-Kuriles

The book would be greatly improved if it had an introductory chapter in which the main geological, tectonic and geomorphological features were discussed Permafrost, a phenomenon typical of a very large part of Siberia, would be much more effectually discussed in an introductory chapter than within the confines of Chapter 4. Because of this chopping up of Siberia into unnatural regions, a very important geological feature has been missed out—namely, the Siberian shield, and its associated plateau lava region, one of the most extensive in the world—the so-called "Siberian Traps" Not only do the numerous basalt lava flows and sills determine the landscape of central Siberia, but also these rocks are often associated with valuable ore deposits and with the newly discovered kimberlite diamond bearing pipes But diamonds are not mentioned in the general index of this book, neither are important tin deposits of the Sikhote–Alin Range, nor many ores of iron, lead, silver and gold, nor coal nor oil All these are important ingredients of physical geography

The translation has not been properly revised, and the number of glaring mistranslations or mistakes in the original text is large Here are a few examples p 4, "Paleozoic sea" for 'Paleogene sea", p 5, "Paleocene" for "Paleogene", "Neocene" for "Neogene", p 106, "Mount Shoria" for "Mountainous Shoria" (Gornaya Shoria), p 115, "Sapropel" (organic mud) for "Sapropelic coal", p 115, "Stratified intrusive vein" (of basalt) for "sill" (of basalt), p 188, "Tungus formation" for "Tunguska formation", p 208, "Mesozoic phase of Alpine folding" for "Kimmerian folding", p 233 "Peridite" for "peridotite" p 257, "Basalt deposits" for "intrusive basalt", p 269, "Tuva" (correct) in the text and "Tuvin" (wrong) in maps 8-V and 8-VI, and p 289, "Caledonian = Lower Paleozoic" for "Caledonian = Upper Paleozoic"

The general impression is that this book was rapidly thrown together by a person or persons more interested in bio-geography than in geology and that the geological–morphological part of it is very poor and contains many original and translation errors

S I TOMKEIEFF

INFINITE-DIMENSIONAL ALGEBRAS

Normed Rings

By M A Naimark Translated from the First Russian edition by Leo F Boron Pp xvi + 560 (Groningen P Noordhoff, Ltd, 1959) 45 D fl, 12 dollars, paper bound 48 75 D fl, 13 dollars, cloth bound

THE theory of finite-dimensional algebras, or hypercomplex number systems, as they used to be called, is one of long standing, going back to Hamilton's quaternions, but only in the past twenty years or so has there been created a general theory for the infinite-dimensional case As in the case of vector spaces, one has to introduce some notion of continuity to obtain a useful theory, the algebraic operations are required to be continuous with respect to an appropriate topology, which, in the simplest cases, is defined by a norm, and we then have a normed algebra

The most familiar normed algebra is that formed by the continuous functions on a closed interval of the real line, the algebraic operations being defined in the natural way and the norm being taken as the upper bound of the absolute value of the function Another important algebra is formed by the set of all functions integrable over the whole real axis, multiplication being defined as convolution, that is,

$$(f * g)(x) = \int_{-\infty}^{\infty} f(y)g(x-y)dy$$

the norm being the integral of the absolute value of the function, this is a special case of the group algebra of a locally compact topological group These algebras are commutative, important non-commutative algebras arise when we consider continuous linear operators in a Hilbert or Banach space

Naimark's book is an admirable survey of the subject up to the appearance of the Russian edition in 1956 The 154 pages of the initial chapter could scarcely be bettered as a brief introduction to the basic ideas of functional analysis The fundamental notions of normed algebras are then introduced, we next come to an account of Gelfand's theory of commutative algebras and their representation by means of continuous functions on a topological space formed by the maximal ideals of the algebra, and its extensions by Shilov and others This is followed by a discussion of the representation of symmetric algebras by means of operators in Hilbert space and descriptions of some special types of algebras The chapter on group algebras constitutes an excellent account of the theory of harmonic analysis on commutative locally compact groups, the non-commutative theory, which is still in a state of rapid development, is touched on lightly The book concludes with a discussion of von Neumann's operator algebras in Hilbert space

Throughout the book the author concentrates mainly on the analytic aspects and applications of the subject, a more algebraic point of view is to be found in Rickart's recent book on Banach algebras The translation is well executed, with only occasional slight infelicities, it is a pity, however, that Mr Boron has not followed the example of the German translation by using 'algebra' instead of 'ring', and so avoided a certain danger of confusion F SMITHIES

COMPUTING UP TO DATE

Modern Computing Methods

Department of Scientific and Industrial Research National Physical Laboratory Notes on Applied Science, No 16 Second edition, completely revised Pp vi+170 (London H M S O , 1961) 21*s* net

THIS second edition of the handbook prepared by staff of the Mathematics Division, National Physical Laboratory, is extremely welcome A complete revision of the 1957 version has been made, revealing the considerable advances of the past few years, with particular emphasis on automatic computing, and also a greater appreciation of the purpose which the book fulfils A hard cover in dark blue adds a becoming air of respectability and greater permanence

The new edition opens with five chapters on linear equations and matrices, including a new one on error analysis, followed by chapters on zeros of polynomials, finite-difference methods, Chebyshev series, two on ordinary and two on partial differential equations, and one each on evaluation of limits, evaluation of integrals, and tabulation of mathematical functions As before, there is a valuable bibliography consisting of carefully selected and annotated references

There are many interesting changes of emphasis between the first and second editions Relaxation methods are now given passing mention only, whereas nearly twelve pages are devoted to Chebyshev series Graeffe's method and the Aitken–Bernoulli process have disappeared from the chapter on solving polynomial equations, and stress is placed on the ill-determination of the roots of high-order polynomials The names of Givens and Householder now appear in connexion with the latent roots of matrices It is perhaps in the chapters on partial differential equations that there is least evidence of progress

Modern Computing Methods should not be regarded as a text-book, nor merely as a book of reference It is a valuable supplement to any good book on numerical analysis, providing a critical selection and appraisal by experts of methods which have been put to the test For this reason it must appeal both to teachers of numerical techniques and to practitioners Not everyone will agree with the choice made, but after all experts must still be allowed to disagree We should wish a great success to this second edition and hope that the hard cover does not betoken a life of more than three or four years, after which the third edition will be eagerly awaited

R A BUCKINGHAM

MASER THEORY

Elements of Maser Theory

By Arthur A Vuylsteke Pp xiii+362 (Princeton, N J D Van Nostrand Company, Inc , London D Van Nostrand Company, Ltd , 1960) 71*s* 6*d*

THE subject-matter of this book falls into two parts, each of which occupies roughly the same amount of space The first is introductory in nature, and covers quantum theory, statistical mechanics radiation and the interaction of radiation with matter, together with a treatment of the necessary mathematical techniques The second part deals with the theory of two- and three-level masers, covers the ammonia maser and the paramagnetic solid maser in detail, and ends with a short discussion of noise theory in general and maser noise in particular Mr Vuylsteke writes with admirable clarity, but one is tempted to question the value of books of this type which attempt to do too much The detailed study of masers is unlikely to be necessary for the student, who might well find much of value in the first half of the book, the professional theoretician, on the other hand, might consider that this part merely adds to the bulk of what could have been a more modest monograph

The section on masers proper is a most useful summary of the theory underlying microwave masers Practical details are mentioned only when they are necessary for appreciation of the theory, or when they themselves have points of theoretical interest The bibliography, as the author admits, is by no means exhaustive, and is complete enough only to support the text, it is a pity that this opportunity could not have been taken to provide the reader with a complete set of references The style is lucid, and the author appreciates the value of explanatory interpolations to bring out essential points Such is the rapidity of developments in this field that the optical maser now fashionable is not mentioned at all, but most of what need be said on microwave maser theory is to be found here The book will prove invaluable as an introduction for those approaching the subject for the first time, and as a summary of the theory for those already familiar with the field

J. H SANDERS

Nuclear Reactor Stability

By Dr A Hitchcock (Nuclear Engineering Monographs, No 11) Pp x+61 (London · Temple Press, Ltd , 1960) 12*s* 6*d*. net

THE neutron multiplication in a reactor is affected by changes in temperature and other physical variables, which are in turn affected by changes in power. This circular situation can cause small changes in power-level to build up, so that the reactor becomes unstable The possibility of unstable behaviour limits the available power output and must be either corrected by control action or, if possible, avoided by correct design This monograph presents concisely, but with an admirably lucid and readable style, an introduction to the theory of reactor stability and the present methods used in establishing conditions for the stability of solid- and liquid-moderated power reactors, a theory which over the past few years has led, ahead of experimental confirmation, to important advances in power reactor control The treatment, avoiding the use of specialized techniques and the jargon of control system analysis, assumes only an elementary knowledge of linear differential equations and Fourier series

The first two chapters show how the physical mechanism of several kinds of instability may be related to the partial differential equations of reactor dynamics In the third and fourth chapters the modal expansion method is applied to yield conditions for instability, first due to temperature effects and then due to the relatively slow effect of fission product (xenon) poisoning The last two chapters deal with voidage instability in boiling reactors and the principles of spatial control

Proceedings of the International Conference on Nuclear Structure

Kingston, Canada, August 29–September 3, 1960 Edited by D A. Bromley and E W Vogt Pp 990 (Toronto University of Toronto Press , Amsterdam North-Holland Publishing Company, 1960) 125*s*

A FREQUENT criticism of conference proceedings is that they tend to present a heterogeneous collection of papers which might more suitably and more speedily have been published in the appropriate technical journals This criticism does not apply to the volume under review Here we have a well-edited handbook of contemporary ideas on nuclear structure It leads in logical sequence from a consideration of the properties of nuclear forces and infinite nuclear matter to a series of contributions on the detailed properties of levels in actual nuclei The book is interfused throughout with contributions on the various reaction mechanisms by which our knowledge of nuclear structure is obtained It is excellently produced with good, clear type and is well illustrated with diagrams reproduced from the contributors' slides This is particularly praiseworthy because this book was available to the delegates within five weeks of the closing date of the conference

The editors have succeeded in effecting a pleasing compromise between the linguistic correctness of a submitted manuscript and the informality of expression in the conference hall This happy blend has been much aided by the inclusion of verbatim reports of the lively discussion which followed the main contributions This book has been made what a good conference report should be It provides those who were there with an accurate record of what was said, while at the same time it preserves something of the atmosphere of the conference hall for their less fortunate colleagues who were unable to be present

D. L Allan

Progress in Dielectrics

Vol 3 Edited by Dr J. B. Birks and Prof J Hart Pp vii+292 (London : Heywood and Co , Ltd , 1961) 63*s*. net.

THE third volume of this series is lively and well written Three of the articles are concerned with electrical properties and molecular structure R H Cole's review "Theories of dielectric relaxation and polarization" is helpful by its lucidity even when it covers old ground, and it contains some illuminating remarks, for example, on the dynamics of the Onsager equation J B Hasted's article "The dielectric properties of water" (and ice) fills a long-felt want This subject might deserve a book, particularly since it is relevant to biology Hasted also gives a useful review of microwave techniques R J Meakins systematically reviews new work on long-chain crystals, hydrogen-bonded compounds, occlusion compounds, and other types of solids the structure of which implies distinctive features of dielectric relaxation

R Stratton's review of theories of electrical breakdown is well presented, but this subject is perhaps being reviewed too frequently. The article by D G Kiely, "Dielectric waveguides and aerials", presents a mathematically difficult subject in a manner comprehensible to the experimentalist The readable article by C W Hamilton on "Recent developments in cable insulation in the United States" is interesting in that it illustrates the gap which still exists between the questions asked by the engineer and the answers provided by the physicist and chemist

V Daniel

Electrical Activity of Single Cells

Edited by Yasuji Katsuki Pp viii+312 (Tokyo Igaku Shoin, Ltd , 1960) n p.

THIS book consists of 18 separate articles by different workers in the field of electrophysiology Their common feature, given by the editor as reason for grouping these articles together, is that they all represent work done in Japan with the intracellular capillary micro-electrode The subjects of investigation include sensory receptors, peripheral and central nerve cells, the neuromuscular junction and cardiac muscle Each article has the strictly limited range of interest of a paper in a scientific journal Furthermore, apparently because the numerous authors were intent on presenting as much of their experimental results as space allowed, very little attention is given to describing the method or to justifying its application in different experimental situations This is particularly unfortunate here, as it is the method which is the unifying feature of the book A welcome exception to this is an article by Takeuchi and Takeuchi, who give a careful account of the application of the voltage-clamp technique to the localized response of the neuromuscular junction

Much of the material in this book has already been published in readily accessible journals (in English), and it is clear that the remainder will soon follow The book does not therefore fulfil any general need

BIOSYNTHESIS OF PORPHYRINS AND CHLOROPHYLLS*

By DR. K. D. GIBSON, MARGARET MATTHEW, PROF. A. NEUBERGER, F.R.S., and G. H. TAIT
Department of Chemical Pathology, St. Mary's Hospital Medical School, London, W.2

IT is now generally accepted that all the carbon and nitrogen atoms of the hæm of hæmoglobin, myoglobin, catalase, peroxidase and the various cytochromes, and probably also those of the dihydroporphyrin of the chlorophyll of green plants and algae and those of the tetrahydroporphyrin of bacteriochlorophyll are derived from the one nitrogen atom and the five carbon atoms of δ-aminolævulic acid. The enzyme which is responsible for the formation of this acid, δ-aminolævulic synthetase, has been found in a great variety of cells and must be presumed to be present in all cells containing either hæm proteins or chlorophylls. This synthetase catalyses the condensation of glycine with succinyl-coenzyme A to give δ-aminolævulic acid, carbon dioxide and free coenzyme A. The enzyme has not been prepared in a high state of purity, but so far it appears that the only co-factor required for this reaction is pyridoxal phosphate.

The importance of this substance in the synthesis of δ-aminolævulic acid was indicated in the work of Lascelles[1] on porphyrin synthesis in *Tetrahymena vorax* and that of Schulman and Richert[2] on hæm synthesis in bird erythrocytes. The participation of pyridoxal phosphate in the enzymic reaction was later directly demonstrated independently by two groups of workers[3,4]. On the basis of the work of Braunstein and Snell, it seems reasonable to assume that pyridoxal phosphate (combined with a specific enzyme protein, possibly through its phosphate group) can react with the amino group of glycine to form an aldimine or Schiff's base, and this then reacts with succinyl-coenzyme A to form a new C—C bond. This reaction has been discussed in detail by Shemin *et al.*[5] and by one of us[6]; moreover, mechanisms of reactions of this type have recently been considered by Perault *et al.*[7], who have applied the molecular orbital method (L.C.A.O. method) to this problem. These workers have confirmed the belief that in the anionic form of the glycine–pyridoxal phosphate complex the carbon atom which is derived from the α-carbon atom of the amino-acid has a high electron density, and thus will react with the electrophilic carbonyl carbon atom of succinyl–coenzyme A.

Inhibition of δ-Aminolævulic Synthetase by Aminomalonate

The requirement for pyridoxal phosphate in the enzymic formation of δ-aminolævulic acid fully explains the inhibitory effects of substances like cysteine, penicillamine or cyanide, which are known to react with the aldehydic group of the coenzyme and thus prevent the formation of the aldimine. We have recently found that the formation of δ-aminolævulic acid can also be inhibited by aminomalonate. The effect of this substance is very marked, even at a low concentration. Kinetic investigation showed that the inhibition is of the competitive type with respect to glycine, and so far it appears that aminomalonate has no marked effect on other enzymes requiring pyridoxal phosphate. Monoethyl aminomalonate is a somewhat weaker inhibitor than aminomalonate, and the diethyl ester has only a relatively slight effect which is of the same order of magnitude as shown by many other amino-acids such as threonine, α-alanine or β-alanine. While kinetic investigations with crude enzyme preparations cannot be considered to give results of exact quantitative significance, the following values give some information of the inhibitory power of aminomalonate: K_m for glycine, $1·4 \times 10^{-4}$ *M*; K_i for aminomalonate, $2·2 \times 10^{-5}$ *M*; K_i for monoethyl aminomalonate, $3·1 \times 10^{-5}$ *M*. It seems likely that aminomalonate combines with the pyridoxal phosphate – enzyme complex, the amino group forming an aldimine with the aldehyde group of pyridoxal. One or two carboxyl groups probably combine with part of the enzyme protein and the resulting complex which cannot react further with succinyl–coenzyme A may be sterically more favoured than the corresponding complex with glycine, which is the intermediate in the enzymic synthesis of δ-aminolævulic acid.

Transamination of δ-Aminolævulic Acid

Shemin and Russell[8] found that with rats given δ-aminolævulic acid labelled with carbon-14 in the carbon atom bearing the amino group, the isotopic carbon appeared in substantial amounts in respiratory carbon dioxide, urinary formate and in the ureido groups of uric acid. They proposed that δ-aminolævulic acid was metabolized by a cyclic pathway, the succinate–glycine cycle, involving the formation of a one-carbon intermediate derived from the δ-carbon of δ-aminolævulic acid. The general metabolic importance of this pathway cannot be assessed at present and the enzymic steps involved have not as yet been properly defined with the exception of the first reaction, the conversion of δ-aminolævulic acid to γ,δ-dioxovaleric acid. A specific transaminase catalysing this reaction has been found in mammalian tissues and in *Corynebacterium diphtheriae*[9,10], we have further examined this enzymic reaction as it might provide a possible control mechanism for the synthesis of hæm and chlorophyll. The earlier workers investigating this reaction have incubated δ-aminolævulic acid and α-oxoglutarate and measured the glutamic acid produced. However, using extracts from *Rhodopseudomonas spheroides*, we have found that the equilibrium appears to be in favour of the production of δ-aminolævulic acid, and we have therefore incubated γ,δ-dioxovaleric acid (supplied by Dr. A. T. Carpenter) with the amino-acid, and estimated δ-aminolævulic acid, for which a sensitive method is available. Moreover, we have found that L-alanine and β-alanine are from five to seven times more effective than glutamic acid in this reaction. Other amino-acids tested showed very little activity. The *p*H optimum is 7·0–7·2, and the reaction is strongly inhibited by pyruvic acid and methylglyoxal, whereas oxoglutarate has little effect. So far no evidence has been obtained which would indicate that the transaminase has any controlling effect on the synthesis of porphyrin or chlorophyll in *Rps. spheroides*.

---

* Substance of two lectures given by Prof. A. Neuberger at University College, London, on May 8 and 11, 1961.

Role of Biotin in the Synthesis of Porphyrin and Bacteriochlorophyll

In an earlier account by one of us[6], the effect of biotin in these reactions was considered, and the possibility was discussed that it acts by catalysing the decarboxylation of α-amino-β-oxoadipic acid present as an intermediate in the pyridoxal phosphate – δ-aminolævulic acid synthetase complex. The evidence in favour of such an assumption was the finding (since confirmed by Lascelles[11]) that δ-aminolævulic acid synthetase activity in extracts of organisms grown in media containing very low concentrations of biotin was apparently specifically reduced if compared with those of δ-aminolævulic acid dehydrase, threonine dehydrogenase, β-hydroxybutyric dehydrogenase or alanine – δ-aminolævulic acid transaminase. The finding, however, that illumination of biotin-deficient organisms with addition of biotin to the medium produced growth and synthesis of porphyrin and bacteriocholorophyll without any increase in the synthetase activity as measured in extracts indicates that any effect of biotin is not exercised directly through a control of the level of δ-aminolævulic acid synthetase activity. Moreover, it was found that other conditions which are unfavourable to formation of bacteriochlorophyll by *Rps. spheroides*, such as a deficiency in nicotinic acid or thiamine, or replacement of malate in the growth medium by acetate, are associated with a depression of δ-aminolævulic acid synthetase activity. It therefore appears that the effect of biotin on the level of this enzyme is unspecific, and that the depression of the synthesis of porphyrin and bacteriochlorophyll by biotin deficiency is caused by some other mechanism, possibly through a reduction in the concentration of pyridoxal phosphate in the cells.

It was also reported earlier[6] that both a commercial preparation of avidin and preparations made in our laboratory by Dr. N. M. Green, containing 2·5 and 4·9 units of avidin/mgm. protein inhibited δ-aminolævulic acid synthetase activity in crude extracts of *Rps. spheroides*. This inhibition appeared to be specific; but when this 'avidin' was pre-incubated with biotin, inhibition was still observed. This seemed surprising, as other biotin-containing enzymes are not inhibited by avidin which has been incubated with biotin before being added to the enzyme under investigation. However, when Dr. Green achieved a further purification of the avidin by column chromatography and made a preparation available to us which had an activity of 9·6 units/mgm., and an estimated purity of 80 per cent, no inhibition of δ-aminolævulic and synthetase activity was obtained. No inhibition was observed with other egg-white proteins such as ovalbumin, lysozyme and ovomucoid, and it must be concluded that some protein not yet identified and which contaminates crude avidin, has a specific inhibitory effect on δ-aminolævulic acid synthetase.

Chemical Conversion of Porphobilinogen to Uroporphyrins

The next step in porphyrin biosynthesis is the conversion of δ-aminolævulic acid to porphobilinogen. This reaction is catalysed by the enzyme δ-aminolævulic acid dehydrase and is fully discussed in a recent review of Bogorad[12]. Porphobilinogen is then transformed to uroporphyrinogen by enzymes to be discussed later, but first it is worth while to consider briefly the non-enzymic reaction which occurs fairly readily under relatively mild conditions. It has been known for some time[13] that on heating porphobilinogen in acid solution, there is obtained a mixture of uroporphyrins in good overall yield and that this mixture contains an appreciable amount of uroporphyrin III. These findings were confirmed by Westall, who isolated porphobilinogen in pure form[14], and by Cookson and Rimington[15], who determined its structure and showed it to be an intermediate in porphyrin biosynthesis. Recently, Mauzerall[16] improved the analysis of individual isomers by decarboxylating the uroporphyrin and estimating the coproporphyrins after chromatographic separation by a modification of the method of Falk *et al.*[17]. In this way it was possible to determine the amounts of isomers I and II and the combined amounts of III and IV in a mixture. Mauzerall was thus able to study the formation of uroporphyrin semi-quantitatively and to determine the distribution of isomers, although the sensitivity of the method is still not very high and the fact that isomers III and IV cannot be separated makes interpretation somewhat difficult. The results obtained by Mauzerall and the earlier workers can be summarized as follows:

(1) The products of the reaction are not uroporphyrins, but uroporphyrinogens, that is, hexahydroporphyrins in which the pyrrole rings are linked through methylene bridges.

(2) If porphobilinogen or any of the four uroporphyrinogen isomers is heated in acid solution, the distribution of the resulting uroporphyrinogen isomers is as follows: 3/4 III + IV, 1/8 I and 1/8 II. In neutral or alkaline solution, no isomer II is formed from porphobilinogen and about half the total porphyrinogen was found to be isomer I.

(3) If the isomerization of uroporphyrinogen in acid is carried out in the presence of [^{14}C]formaldehyde, radioactivity is found in the final mixture of uroporphyrinogens; however, no such incorporation of formaldehyde takes place when uroporphyrins are heated in acid or when uroporphyrinogens are heated at neutral or alkaline *p*H. Radioactivity is found in uroporphyrinogens when these are formed by heating solutions of porphobilinogens in the presence of [^{14}C]formaldehyde and this occurs at acid, neutral and alkaline *p*H values.

(4) In the isomerization of uroporphyrinogen in acid solution and in the formation of uroporphyrinogen from porphobilinogen in acid or neutral solution, yields of up to 80–87 per cent of total porphyrinogen are obtained. Although some material behaving like dipyrrylmethanes was formed, no evidence was obtained for the presence of higher linear polypyrrylmethanes, and it must be assumed that once a linear tetrapyrrylmethane with one aminomethyl or hydroxymethyl group is formed, cyclization to the macrocycle, uroporphyrinogen, is very fast.

Enzymic Conversion of Porphobilinogen to Uroporphyrinogen

The enzymic conversion of porphobilinogen to uroporphyrinogen has been studied in extracts of *Chlorella*, spinach leaf and wheat germ, and in fowl erythrocytes, by Bogorad, Mauzerall, Granick and Rimington (for review see Bogorad[12]) and more recently by Lockwood and Benson[18], and in *Rps.*

spheroides by Heath and Hoare[19]. The main findings were as follows: the product of the reaction catalysed by the crude enzyme system is uroporphyrinogen III and not uroporphyrin III. When the crude enzyme system is heated to 55° or 60° (depending on *p*H) the product is not uroporphyrinogen III, but isomer I. From the heated extracts an apparently single enzyme called porphobilinogen deaminase can be obtained which can be further purified and which converts porphobilinogen quantitatively into uroporphyrinogen I. The second and more heat-labile enzyme, called uroporphyrinogen isomerase, has no detectable action on uroporphyrinogen I or on porphobilinogen alone. Its substrate is either a linear tetrapyrrole or, what seems less likely, a dipyrrolic or tripyrrolic substance which is converted by the isomerase to uroporphyrinogen III through further condensation with one or two porphobilinogen molecules.

Although, as pointed out above, isomer analysis of porphyrins is neither so sensitive nor so specific as might be desired, it appears from evidence at present available that enzymic condensation does not give rise to uroporphyrinogens II and IV. It also appears that formation of uroporphyrinogen by the two enzymes is quantitatively paralleled by consumption of porphobilinogen. Moreover, neither the intact nor the heat-altered enzyme preparation incorporates radioactive formaldehyde into porphyrin. This finding is in accordance with the observations of Bogorad[20] and of Carpenter and Scott[21,22], that opsopyrroledicarboxylic acid and isoporphobilinogen are not substrates for the deaminase or isomerase; in fact, the two substances act as competitive inhibitors.

Many suggestions have been put forward to explain both the chemical and enzymic condensation of porphobilinogen to uroporphyrinogen and particularly the proportions of isomers formed. Most of the schemes are not readily compatible with the experimental findings; particularly those obtained in the enzymic reaction. Porphobilinogen deaminase might perhaps best be visualized as catalysing the addition of a porphobilinogen molecule to the free α-position of another porphobilinogen molecule or a dipyrrole or tripyrrole of the structures *PA PA*—$CH_2NH_3^+$, *PA PA PA*—$CH_2NH_3^+$ (*A* stands for acetyl and *P* for propionyl side-chain). It is postulated that the action of this enzyme stops at the linear tetramer stage and that the deaminase is highly specific with regard to the nature of the β-substituents, both in the electrophilic and the nucleophilic partner of each step of the reaction. Alternatively, the condensation of the four porphobilinogen units on the enzyme surface may be simultaneous. In the absence of the isomerase the linear tetramer will cyclize spontaneously to give uroporphyrinogen I. The findings of Mauzerall[16] have clearly shown that at the tetrameric stage cyclization is greatly favoured over further linear addition, and this author has also adduced convincing reasons for such preference.

In an important paper, Mathewson and Corwin[23] suggested that the substrate of the isomerase is the linear tetramer and that this enzyme catalyses an attack by the $CH_2NH_3^+$ group, not on the free α-position of the pyrrole at the other end of the tetramer chain, but on the 'occupied' α-position of that pyrrole. The cyclic structure thus produced will then become re-arranged to give uroporphyrinogen III. Mathewson and Corwin have also proposed that three of the rings in the linear tetramer are in the pyrrolenine form, thus giving even greater flexibility to the structure. In the cell, co-operation between the two enzymes is almost perfect and thus only minute traces of uroporphyrin I are normally formed. In congenital porphyria this co-operation breaks down, with the result that the linear tetramer accumulates and this spontaneously changes into uroporphyrinogen I.

The mechanisms operating in the non-enzymic formation of uroporphyrinogens from porphobilinogen are more obscure than those involved in the enzymic reaction. The scheme proposed by Mauzerall[16] explains the incorporation of formaldehyde and the isomer ratios, but the suggested mechanism of Mathewson and Corwin, though satisfactory for explaining the enzymic condensation, does not readily accommodate the exchange with formaldehyde so convincingly demonstrated by Mauzerall.

Conversion of Uroporphyrinogen III to Protoporphyrin

The decarboxylation of uroporphyrinogen III to coproporphyrinogen is a straightforward reaction and requires little comment in this discussion. The next step, however, is more complex and has been investigated recently.

Sano and Granick[24] have described an enzyme which is present in a great variety of tissues, but is found in particularly high concentration in the liver, bone marrow and small intestine, and which converts coproporphyrinogen III to protoporphyrin IX. This enzyme, which has been purified approximately twenty times, is localized primarily in the mitochondria. The enzyme responsible for the condensation of succinyl coenzyme A and glycine to give δ-aminolævulic acid is also localized in particulate structures of the cell, whereas δ-aminolævulic acid dehydrase is present in the cytoplasm. It would therefore appear that δ-aminolævulic acid is synthesized in mitochondria, then leaks out into the cytoplasm, to be converted ultimately into coproporphyrinogen, which migrates back again into the mitochondria, to be transformed into protoporphyrin. Sano and Granick suggest that this localization might permit a control of porphyrin synthesis by the cell through permeability factors.

The enzyme which acts on coproporphyrinogen removes two hydrogen atoms and a carboxyl group from each of the two propionic acid side-chains in rings *A* and *B*, and at the same time porphyrinogen is converted to porphyrin. The latter reaction occurs fairly readily in the presence of oxygen and is not necessarily catalysed by an enzyme. The first two reactions, however, appear to be part of a concerted mechanism as the appropriate diacrylic acid is not an intermediate. Oxygen acts in this somewhat impure system as a hydrogen acceptor and cannot be replaced by any other co-factor tested. This is of considerable general importance, since it might indicate that oxygen was present in the atmosphere of the Earth at a time in evolution when protoporphyrin first appeared.

Biosynthesis of Chlorophyll and Bacteriochlorophyll

The work of Granick[25] has produced strong presumptive evidence that chlorophyll and bacteriochlorophyll are synthesized by green plants and certain bacteria from protoporphyrin Although the enzymic steps involved cannot as yet be clearly defined, Granick has proposed, mainly on the basis of work with mutants of *Chlorella*, that the following pathway operates

protoporphyrin → magnesium protoporphyrin or
protoporphyrin monomethyl ester →
magnesium protoporphyrin monomethyl ester → → →
magnesium vinyl phæoporphyrin a_5 →
magnesium vinyl phæoporphyrin a_5 phytyl ester →
chlorophyll a → bacteriochlorophyll

Although this is a rational scheme, it does not necessarily follow that compounds which accumulate in mutants, in which the enzyme for a particular step in a biosynthetic pathway is absent, are true intermediates It is now known, for example, that intermediates in hæm synthesis are porphyrinogens and not uro- and coproporphyrins, although these latter substances may be accumulated or excreted under certain conditions In a similar manner, protoporphyrinogen or one of its derivatives might be a precursor of chlorophyll

We have recently been able to define at least one step in Granick's pathway more clearly In work aimed at elucidating the effect of biotin, it was observed that ethionine at a concentration of about 10^{-4} *M* inhibited bacteriochlorophyll synthesis by *Rps. spheroides* almost completely, and at the same time produced a markedly increased excretion of copro- and uro-porphyrin into the medium in which the organism was illuminated At that concentration very little inhibition of protein synthesis or growth occurred Many other substances, such as methionine, other amino-acids, keto-acids and related compounds, amino-acid antagonists and other inhibitors of protein or nucleic acid synthesis, were tested to see whether they produced similar effects The results were negative with the exception of threonine, the addition of which to the medium at a concentration of 10^{-3} *M* inhibited bacteriochlorophyll synthesis and produced a considerable increase in porphyrin excretion The effects of ethionine and of threonine were reversed by methionine and by homocysteine, but not by cysteine or serine The effect of threonine was also reversed by homoserine This suggested that ethionine interfered either with the synthesis of methionine or its utilization and further that methionine had a specific function in the synthesis of chlorophyll from protoporphyrin involving the methyl-group donating capacity of this amino-acid The effect of threonine was baffling at first, until it was realized that methionine and threonine share a biosynthetic pathway leading from aspartic acid through aspartyl β-phosphate and aspartyl β-semialdehyde to homoserine The latter can be converted either to homocysteine and methionine or to threonine. Thus threonine could inhibit methionine synthesis from aspartic acid by a feed-back mechanism involving either repression or inhibition of one of the enzymes catalysing the various steps leading to homoserine (Recent results have shown that in *Rps spheroides* threonine is a competitive inhibitor of homoserine dehydrogenase, although it does not repress the formation of this or any of the other enzymes involved in homoserine synthesis)

The most likely step in the biosynthesis of chlorophyll involving the methyl group of methionine is the methylation of protoporphyrin or of its magnesium complex to give magnesium protoporphyrin monomethyl ester Organisms were illuminated in a suitable medium to which methionine labelled with carbon-14 in the methyl group was added At the end of the experiment, bacteriocholorophyll was isolated, purified and counted The chlorophyll had high radioactivity, which was shown on degradation to be entirely confined to the methyl ester group (Table 1) With appropriate amounts of [^{14}C]methionine the dilution was only about three times, and this indicated that the methyl group of methionine was almost certainly the immediate and specific precursor of the porphyrin ester carbon atom The less specific utilization of formate for the methyl ester group of chlorophyll had already been shown some time earlier[26] More recently two of us, using chromatophore preparations of *Rps spheroides*, have been able to demonstrate directly the methylation of magnesium protoporphyrin to its methyl ester by *S*-adenosylmethionine[27]

Table 1 LABELLING OF BACTERIOCHLOROPHYLL SYNTHESIZED IN THE PRESENCE OF [METHYL-^{14}C]METHIONINE

Rps spheroides were illuminated at 2 mgm dry wt /ml in Mixture I of Lascelles (ref 31) for 18 hr at 32–34° [Methyl-^{14}C]methionine (10^{-4} *M*) was also present The bacteriochlorophyll was extracted and purified A portion of it was degraded in methanolic potassium hydroxide The methanol, bacteriochlorin and phytol were isolated and estimated for radioactivity by liquid scintillation

Fraction	Specific radioactivity (counts/min /μmole)
Bacteriochlorophyll	9,800
Methanol	9,900
Phytol	64
Bacteriochlorin	6

Control of Synthesis of Bacteriochlorophyll

Micro-organisms such as *Rps spheroides* or *Rhodospirillum rubrum* can grow either anaerobically in the light or aerobically in the dark, using as source of energy a number of aliphatic acids or alcohols Elsden and Ormerod[28] showed that *R rubrum*, under aerobic conditions in the dark, metabolized all substrates by the tricarboxylic acid cycle Anaerobically in the light, acetate and butyrate are metabolized by this cycle, but propionate, malate and succinate are utilized by another pathway which is not inhibited by fluoroacetate The question therefore arises how the type of metabolism is regulated Following van Niel's pioneer work, this problem was first systematically investigated by Cohen-Bazire, Sistrom and Stanier[29] They showed that organisms grown aerobically in the dark contained little pigment, whereas those grown anaerobically in the light contained relatively large amounts of bacteriochlorophyll, that transference of organisms from the dark to light resulted, after a lag phase, in synthesis of pigment, that exposure to oxygen of organisms growing in the light inhibited synthesis of pigment immediately, that is, without a lag phase, and removal of oxygen resulted in immediate resumption of synthesis of pigment and that increasing light intensity beyond a certain value had the same effect as an increase of oxygen tension On the basis of these results, they suggested that the synthesis of both bacteriochlorophyll and carotenoids is controlled by the state of oxidation or reduction of a carrier of the electron-transport chain They did not specify the identity of the substance postulated or the mechanism by which this control operates

Lascelles[11,30] examined changes in the activities of various enzymes involved in porphyrin synthesis in extracts from cells grown under conditions under which the rate of bacteriochlorophyll synthesis is either high or low When synthesis of pigment was inhibited or when levels of pigment were low, the activities of δ-aminolævulic acid synthetase and dehydrase were also reduced, and synthesis of these enzymes was apparently inhibited She also found that the transference of organisms from highly aerobic conditions in the dark to conditions of low oxygen tension in the dark, or to anaerobic conditions in the light, not only caused pigment synthesis but also resulted in an increase in the activities of δ-aminolævulic acid synthetase and dehydrase This adaptation could be inhibited by inhibitors of protein synthesis Lascelles[11] observed that hæmin represses formation of the synthetase and dehydrase in whole cells, and there was some evidence that formation of these two enzymes could be regulated by the concentration of iron porphyrins present in the cells We have found that hæmin, in addition to its repressive effect on the formation of these enzymes, inhibits the synthetase activity in cell extracts and that protoporphyrin inhibits the dehydrase activity Accumulation of hæmin and of protoporphyrin under certain conditions of growth may thus reduce synthesis of pigment both by repression of enzyme formation and by inhibition of the activities of enzymes already present in the cells

There is, however, good evidence that levels of porphyrins and hæm are not the only factors controlling synthesis of pigment The experiments on the effects of ethionine and threonine demonstrate the importance of the methylation step, and the excessive amounts of porphyrins excreted in the cells in the presence of moderate quantities of ethionine and threonine in the medium suggest that porphyrin formation is normally controlled by a substance X, possibly a phæoporphyrin derivative, which occurs after magnesium protoporphyrin in the biosynthetic pathway of bacteriochlorophyll If this substance is not synthesized, for example, owing to inhibition of the methylation of magnesium protoporphyrin or to inhibition of methionine formation, porphyrin synthesis 'runs wild' and excessive amounts are formed which are released into the medium In addition to these direct mechanisms of control, it appears that in general the rates of formation of chlorophyll and of carotenoids are closely parallel, and we know little about the factors regulating the formation of the latter Similarly, phytol is a component of the bacteriochlorophyll molecule and its mode of synthesis is still obscure, although it would appear likely that it is derived from a carotenoid or a carotenoid precursor Mechanisms which increase or depress terpene synthesis might therefore also control synthesis of bacteriochlorophyll through the availability of the phytol side-chain.

ANIMAL BEHAVIOUR

A SYMPOSIUM on animal behaviour was held on September 4 by Section J (Psychology) of the British Association for the Advancement of Science, during the recent meeting at Norwich As was pointed out by the chairman, Mr D E Broadbent (Medical Research Council Applied Psychology Research Unit, Cambridge), the Section has usually considered primarily human behaviour, but in this it is ceasing to be in step with university departments of psychology, which are devoting more effort than they once did to research on animals Animal behaviour is a subject of great interest in itself It also has relevance to human beings, because it reveals simple general principles about behaviour that may also apply to men, and it makes possible experiments on causal factors in behaviour which cannot, for moral and practical reasons, be performed on men Thus the influence on behaviour of rewards, of the structure of the brain, of restricted infantile experience, and of drugs and instincts, can be studied in animals, and papers on each of these topics were included in the symposium

Mr H M B Hurwitz and Dr. J R Millenson (Birkbeck College, University of London), proceeded to discuss and demonstrate the control of behaviour by reward Their emphasis was on the possibility of building up valid empirical statements about observed relationships without appeal to theoretical concepts Thus, if a response R was followed by a reinforcing agent S^r, such as food, the frequency of R would increase If S^r ceased to follow R, the latter would decrease in frequency Such statements could be made without any discussion of events within the animal In a similar way, but with more complex experimental manipulations, behaviour such as problem solving or delayed reaction could be studied

The authors then demonstrated a pigeon and a rat the behaviour of which had been shaped in a complicated fashion The pigeon would look at three keys, peck the middle one, and observe a coloured light on that key which was sometimes red and sometimes green One of the other two keys was red and one green, and the bird would then peck the key which was the same colour as the middle key This sequence occurred continuously at a rate rather faster than most humans could make the comparison The method of training had been, first, to teach the bird that food would appear in a certain place when a light was on, then to teach that pecking either of the two end keys would produce the food, this training was followed by withholding the food unless a peck at the centre key was made before the peck at the end key, and so on until the full sequence was learned

The rat had been taught in a similar way to press one lever five successive times, and then press another lever to obtain food Both animals behaved as they had been taught despite the strange surroundings and the audience and provided a most convincing demonstration that suitable manipulation of reward could indeed control behaviour so as to produce exceedingly complex learned actions

Dr L Weiskrantz (University of Cambridge) emphasized the importance of such behavioural techniques, but he was concerned with the brain and with its relation to behaviour rather than with purely external observations of animals Historically, the cortex of the brain had been regarded as composed of projection areas through which messages entered and left, and association areas which were more general in function Indeed, according to Lashley's principle of mass action, the amount of deterioration, in performance in mazes, produced by removal of association cortex from a rat's brain depended on the weight of cortex removed and not the location More recent research had shown both that the projection areas were less specific and that the association areas were more so than had been thought Removal of the projection area which was fed by the ear had little effect on the ability of an animal to detect sounds On the other hand, damage to the frontal association areas would produce an impairment in the ability to remember, over a short period, which of several possible hiding places contained food The latter impairment did not occur with damage elsewhere in the brain Similarly, damage to the temporal lobes would affect the ability to discriminate between two stimuli whereas damage to the frontal lobes would not Thus different parts of the brain do have different functions

Experiment in this area is made difficult by the irreversible nature of a lesion in the brain once the frontal lobe has gone the animal cannot be tested again in its normal state Recent work at Cambridge had, however, explored the possibility of temporary interference with particular regions by electrical stimulation, and it seemed that the ability to make delayed responses to hiding-places could indeed be removed temporarily while stimulation was being applied in the frontal lobes The animals were afterwards normal in their performance Once again different parts of the brain showed different effects

Whereas the classical view of the nervous system was of a series of levels, in which the lower mechanisms dealt with isolated actions and higher ones with combined and co-ordinated ones, a different interpretation was now gaining support On this view the nervous system might rather be compared with a candle in which the wick dealt with gross and undifferentiated action of the whole organism, and the outer skin of the candle dealt with finely discriminated functions To take another analogy, on the old view, lower levels might be compared with isolated instruments and the cortex to the whole orchestra, on the new view, the contrast was rather between the orchestra tuning up, all simultaneously, and the orchestra playing in complex harmony

Dr Weiskrantz ended with a clear and well-reasoned argument for a physiological approach to behaviour as well as the approach in which actions alone are studied without reference to events within the animal, and as well as the approach in which mechanical models are constructed without physiological reference He regarded these approaches as healthy in their scepticism, but negative, and firmly supported the importance of the brain in behaviour It may be added that his paper was both witty and modest, and that it produced a deep impression on the audience

Dr R Stretch (Queen's University, Belfast) gave a general review of experiments on the early experience of animals, including a few which show effects of ante-natal experience It appears that exposure of pregnant rats to frightening situations may produce offspring which are unduly susceptible to fear possibly through some ill-understood hormonal mechanism Most research has, however, concentrated on early post-natal experience, and in this area the relationships seem to be complex Electric shock administered to rats during infancy seems, for example, to produce adults which are more resistant to emotional disturbance On the other hand, if animals are reared in a very restricted environment they seem as adults to be poor in ability to learn There is some evidence that exposure to a complex environment in infancy produces adults with a lower concentration of cholinesterase in the brain, and this may be related to the differences in ability There are also genetic differences as well as those produced by environment, and in this connexion it is interesting that wild rats differ from laboratory rats in the extent to which they will show curiosity or exploration Wild rats avoid novel objects, while laboratory animals will investigate them and even feed in their presence There may therefore be some interaction between anxiety and curiosity, and the effects of early experience on curiosity are of interest

Dr Stretch then turned to some experiments of his own on this latter problem One group of rats was kept in ordinary laboratory wire-mesh cages for the period just after weaning, while another group of rats was kept in restricted cages through the walls of which they could not see In the latter case there was little background noise, and the environment was in general a rather unstimulating one As adults the rats were tested for curiosity in two ways One of these was a maze shaped like an *H*, the measure of exploration being derived from the number of parts of the maze entered On this test the animals which had had a restricted environment explored more Another test could, however, be applied For this a box was used, in an alcove of which novel cards with patterns on them were placed, and a record was kept of the extent to which the rats entered the alcove rather than the rest of the box On this test the restricted rats gave a lower score As Dr Stretch pointed out, these results suggest that rats with a restricted early experience were more fearful They therefore avoided particular novel objects, but if placed in a completely novel situation ran around looking for a means of escape There are therefore implications both for the methods to be used in studying curiosity and also for the possible mechanism by which variety of early experience has its effect

The last speaker, Dr J M Cullen (University of Oxford), was a zoologist rather than a psychologist Accordingly he gave more attention to the natural behaviour of animals than did the other members of the symposium His particular interest was the possibility of separating different classes of behaviour as affected by one drug rather than another By this means one might ultimately disentangle the mechanism by which drugs affect behaviour The animal which he had studied was the stickleback, and the drug benactyzine

The stickleback lives in schools in the winter, but in the breeding season each male defends a territory in which it builds a nest It courts an approaching female, she lays her eggs in the nest, departs, and the male then looks after the eggs When defending the territory, the male will attack other males close to his own nest, but flee from them at greater distances The border-line between these two behaviours moves nearer to the nest under benactyzine, which suggests at first sight that fear is increased

When the female appears, drugged males less frequently court her, and are more likely to attack her than undrugged males are This is not altogether consistent with the effect on size of territory, but might perhaps be explained by supposing that sexual behaviour is even more sharply reduced than fear is On the other hand, kicking the tank in which the fish live causes them to cluster into a school, which suggests that schooling is a fear response and the drug reduces schooling rather than increases it

Feeding is reduced by frightening stimulation and also by the drug but closer examination shows that the effects are rather different In feeding, the stickleback orients towards the food, possibly several times, before each grasp at it When frightened there are fewer grasps but also fewer orientations per grasp, whereas under benactyzine there are fewer grasps with a normal number of orientations per grasp The latter type of behaviour also results simply from reduced hunger, so that the drug is in this respect apparently similar to a reduction in hunger

The common factor in all these effects might perhaps be a reduced responsiveness to visual stimulation, and in fact sticklebacks placed in a situation where a striped wall rotates around them are less responsive to this stimulation At the moment the most promising hypothesis is therefore that the drug reduces responsiveness rather than the strength of one category of behaviour, but the experiments remain an illustration of the way in which a knowledge of instinctive patterns may be used to analyse the operation of drugs

It was clear from all four papers that work on animal behaviour is developing rapidly, and that important principles are beginning to emerge

D E Broadbent

NEWS and VIEWS

Pharmacology at St. Bartholomew's Hospital Medical College: Prof. J P. Quilliam

Dr J P. Quilliam, at present reader in pharmacology in the University of London at St Bartholomew's Hospital Medical College, has been appointed to the newly created chair of pharmacology at that Medical College as from October 1. Dr Quilliam graduated with honours (physiology) in the University of London, and took his M Sc in 1938, and his M B . B S (London) in 1941. After a period of war service, in the Royal Air Force, he was appointed lecturer in pharmacology at King's College, London, and in 1946 he was appointed part-time lecturer in pharmacology at St Bartholomew's Hospital Medical College to assist in the early development and expansion of that Department In that early development he played a very active part and was appointed senior lecturer in charge of the Department and later reader in pharmacology in 1958. Dr Quilliam has built up at St Bartholomew's a very active Pharmacology Department with wide research interests and comprehensive teaching courses for medical, dental and science students He has developed a department which is particularly well equipped for the use of electro-pharmacological techniques for research in pharmacology and for the teaching of that subject He has built up a very strong and enthusiastic research team, with many postgraduate workers in his group, and he has attracted for his work important and valuable research grants from the United States His research interests are manifold and his particular interests have centred on neuromuscular and ganglionic transmission and its modification by centrally-acting drugs He has had wide experience of teaching methods, and he has spent a year as a Fellow in residence at Johns Hopkins University, Baltimore He has had much experience as an examiner in the University of London and other universities in Britain, and is the chairman of the Board of Studies in Pharmacology in the University of London He is a member of the General Optical Council He has carried out important editorial duties as an editor of the *British Journal of Pharmacology and Therapeutics*, and his own publications involve investigations on the pharmacological action of hypnotic drugs, fluorophosphonates and many other drugs

New Zealand Department of Scientific and Industrial Research: Senior Research Fellowships

The New Zealand Department of Scientific and Industrial Research has announced the award of the 1961 Senior Research Fellowships to Dr B H Howard, principal scientific officer, Rowett Research Institute, Bucksburn, Aberdeen, Scotland, and to Dr R Melville, principal scientific officer, Royal Botanic Gardens, Kew, Richmond, Surrey, England. Dr Howard's work has been concerned since 1954 with the study of the biochemistry of micro-organisms of the rumen, under Dr D P Cuthbertson, director of the Rowett Research Institute Prior to that he was studying biochemistry of micro-fungi, under Prof. H Raistrick at the London School of Hygiene and Tropical Medicine He has published several papers, and in his work under the Fellowship in New Zealand he hopes to apply techniques used in the United Kingdom to the different ruminal flora and fauna found in New Zealand ruminants Dr Melville is in charge of the Australasian Section of the Herbarium at Kew and is working mainly on Australian plants and to some extent on New Zealand plants, in particular Ranunculaceae, Epacridaceae and Rutaceae He has published several papers, in particular on *Ulmus*, and is very interested in the application of biometrical methods to taxonomy and the evolution of the angiosperm flower He will be working in the Botany Division of the New Zealand Department of Scientific and Industrial Research

Zoological Society of London : Senior Research Fellowships

Dr I W Rowlands has been appointed by the Zoological Society of London as Senior Research Fellow in reproductive physiology He will take up his appointment on January 1, 1962, and will be in charge of the Wellcome Institute of Comparative Physiology which is to be built in the Society's grounds next year For the past twelve years Dr. Rowlands has been on the staff of the Agricultural Research Council and has worked at the Institute of Animal Physiology, Babraham, Cambridge. on problems concerned with the ovarian cycle of mammals Before this, he worked at the Wellcome Veterinary Research Station, Frant, Sussex Dr Rowlands began his research career at the University College of North Wales with Prof F W Rogers Brambell and was afterwards with Dr A S Parkes at the National Institute for Medical Research in London

Research Fellowships and Studentships

Dr G H Manley, who is at present on the staff of the Department of Zoology, University of Nottingham, has been appointed to a research fellowship, and will take up his appointment on January 1, 1962, working initially with Prof A St G Huggett at St Mary's Hospital Medical School, on reproductive behaviour of the lower primates Mrs A D Woodhead, who was been appointed to a research fellowship, has already taken up her appointment, and will work at the Fisheries Laboratory, Ministry of Agriculture, Fisheries and Food, Lowestoft, on the physiology and reproduction of fish Mr D B A Symons and Mr G Glough have been appointed to research studentships

Science at the British Council ·

Mr E Bolton King

Mr E Bolton King will retire from the posts of assistant controller, Arts and Science Division (Science Group), and director, Science Department of the British Council, at the end of this year He will immediately thereafter take up the post of British Council science officer in Chile Mr Bolton King was educated at Warwick School and Balliol College, Oxford, where he was a mathematical exhibitioner and obtained first-class honours in physics finals He was elected to a research studentship at Christ Church, Oxford, and carried out research at the Clarendon Laboratory, largely on photo-electricity Later he formed the Oxford Instrument Co Early in the war he joined the Ministry of Supply Rocket Team under Sir Alwyn Crow and was engaged on rocket development, with special emphasis on proximity fuses, investigation of the performance of British and enemy rocket weapons in the Mediterranean theatre, and liaison with rocket development in the United States, where he was an assistant director of the British Commonwealth Scientific Office At the end of the War he went to Germany in connexion with the British firings of the V-2 rocket and became superintendent of the Ministry of Supply Establishment, Cuxhaven

Dr. P. A. I. Tahourdin, O B.E.

Dr P A I Tahourdin will succeed Mr Bolton King as an assistant controller, Arts and Science Division, with responsibility for various departments, including the Science Department Dr Tahourdin graduated in physics at Oxford in 1943 and afterwards obtained a Ph D after nuclear work under the late Sir Francis Simon He joined the British Council in 1946 and has served as science officer in Italy, assistant representative in Yugoslavia, and representative in Israel He will assume his new duties early in 1962

Mr F. M Beatty, M B E

Mr F M Beatty will become director of the Science Department in April 1962 He was trained as a physicist at Cambridge, taking his degree in 1940, and served during the War in the Royal Navy He joined the British Council in 1946 and has served in the Science Department at headquarters, as science officer in Poland and in Austria, assistant representative/science officer in Brazil and, since 1959, as deputy representative in Pakistan

Delegation from Academia Sinica in Britain

On the invitation of the President and Council of the Royal Society, a delegation from the Academia Sinica in Peking is visiting Britain during October16–November 2 The members of the delegation are: Dr Chu Ko-chen, vice-president and department member of Academia Sinica (meteorologist), Dr. Pei Shih-chang, department member and director of the Institute of Biophysics, Academia Sinica, Dr Wang Shou-wu, deputy director of the Institute of Semiconductors, Academia Sinica; Dr Chang P'ei-lin, deputy director of the Institute of Metals, Academia Sinica Mrs Chu is accompanying the delegation Short visits are being made to Cambridge, Edinburgh and Oxford, and Dr Chang is also visiting Sheffield. Visits will be made to university scientific departments, the National Physical Laboratory, the National Chemical Laboratory and other scientific institutes On October 19 a special presentation and lecture on "Astronomy in Classical China" was arranged at the London Planetarium

The Wellcome Trust: Grants for Research on Tropical Anæmias

The Wellcome Trustees are to provide up to £100,000 to assist an integrated programme of research by several groups of workers into the severe anæmias prevalent in tropical countries, with special reference to the malabsorption syndrome and tropical sprue The Trustees already support work in this field by Dr Henry Foy and Dr Athena Kondi at the Medical Research Laboratories, Nairobi, Kenya, and Dr Selwyn Baker and others at the Wellcome Sprue Research Unit at the Christian Medical College, Vellore, South India Under the new arrangements the work of both teams will be associated with that of a new Wellcome Laboratory of Tropical Hæmatology which is to be established in Prof J V. Dacie's department at the Postgraduate Medical School of London, Hammersmith The total allocation of £100,000 for the work on tropical anæmias and kindred disorders is made up as follows £45,000 to build and equip the Wellcome Laboratory of Tropical Hæmatology at Hammersmith, £14,000 to organize and maintain a scheme of close co-operation between the groups led by Dr Foy, Dr Baker, Dr D L Mollin of the Hammersmith Laboratory, and a Royal Army Medical Corps team in Singapore, £25,000 for the continued support of Dr Baker's unit in Vellore, £15,000 for new X-ray equipment at Vellore

Awards in the United Kingdom and the United States

OTHER major grants in aid of research out of the total of £248.00 distributed by the Trust during the past half-year included £40,000 to Prof H O Schild and others for the extension to the Pharmacology Building at University College, London, £15,000 to Prof J D Lever to purchase an electron microscope for the Department of Anatomy, University College of South Wales and Monmouthshire, Cardiff, £13.500 to Prof D H R Barton for the purchase of a nuclear magnetic resonance spectrometer for the Department of Organic Chemistry, Imperial College of Science and Technology, £10,500 to Dr D P Cuthbertson for the purchase of new radiographic equipment for the Rowett Research Institute, Aberdeen, £10,000 to Prof H E de Wardener, Department of Medicine at the Fulham branch of Charing Cross Hospital, £9,850 to Prof F W Rogers Brambell to increase the accommodation for post-graduate research workers in the Department of Zoology, University College of North Wales, Bangor. £4,000 to Dr A H Harthoorn, to provide a mobile laboratory for field research in comparative physiology, University College of East Africa, Nairobi A five-year senior Wellcome research fellowship has been provided for Dr Karlis Adamsons in the Columbia-Presbyterian Medical Center, New York City, at a cost of 50,000 dollars His work will be concerned chiefly with the physiology of the new-born

New Member of Trust

THE Wellcome Trust announces that Mr Lancelot Claude Bullock, who was appointed a trustee under the will of the late Sir Henry S Wellcome, has retired. For many years he was senior partner in the London firm of solicitors, Markby, Stewart and Wadesons, where his associations with Sir Henry Wellcome go back to the time he was asked to advise and draft the will under which the Trust was created He is succeeded by Mr Robert Malleson Nesbitt, also of Markby, Stewart and Wadesons

The State and the Freedom of the University

PROF M BOUCHARD, writing in *Science and Freedom* (No 19, June 1961) on "The Universities in France Freedom and Autonomy", expresses some concern at the effect on university autonomy of the growing dependence of the universities on State support While the maintenance of university freedom depends in the last resort on the moderation and liberal outlook of the State, Prof Bouchard is no less concerned that the individual members of the universities must be allowed full scope for their inquiries and research in whatever field they please, without let or hindrance They must be free to form their own conclusions and say what they believe to be true In France, university teachers have the status of Civil servants and are protected from all arbitrary measures by a special legal clause which offers security so long as the spirit of independence is kept alive in the universities, and Prof Bouchard pleads that care should be given to the preservation of this vital principle To the same issue, Prof L Massart contributes a note on the problems and prospects of the Belgian universities Pointing out that the appointments of teaching staff are not immune from political influence, he stresses, however, that the real problems of the universities in Belgium arise out of their growing dependence on State support and the increasing number of students He is disturbed at the persistence of obsolete methods of teaching, the failure to increase the number of students trained for research commensurately with the national needs and the effects of inbreeding from which the university system suffers. He believes that a thorough reappraisal of the university structure in Belgium is required While the number of students has increased from 10,307 in 1938–39 to 26,057 in 1958–59, and the number of graduates from 1,995 to 4,930 over the same period, the number of doctorates has only risen from 79 to 120, a 40 per cent drop in the rate per 100 graduates

The Berkshire, Buckinghamshire and Oxfordshire Naturalists' Trust, Ltd

THE first annual report of the Berkshire, Buckinghamshire and Oxfordshire Naturalists' Trust, Ltd, which was incorporated as a limited company on January 9, 1961, covers the year 1960 (Pp 7 Kennington, Oxford Berkshire, Buckinghamshire and Oxfordshire Trust, Ltd, 146*a* Poplar Grove, 1961) At its incorporation the Trust had 328 members, and the major task of the Provisional Executive Committee during the first year was the preparation of a draft constitution which was approved at a meeting of members on November 12, 1960 The objects of the Trust, as set out in its memorandum of association, are to record and investigate places and objects of botanical, zoological, geological, archæological or scientific interest, or of natural beauty, and to protect these from injury, ill-treatment or destruction, to establish, form, own, maintain and manage nature reserves or bird sanctuaries, to encourage the breeding of wild-birds, insects and plants which are harmless, useful, beautiful or rare, and to promote, organize, carry on and encourage study and research for advancing knowledge in the natural sciences The Trust has already been concerned with threats to several important sites In December 1959 it joined with the Nature Conservancy and other bodies in successfully resisting the proposal to build a 250-ft radio tower in Little Lenham Wood, near Beacon Hill It has also joined with the Banbury Ornithological Society in asking for the preservation of certain woods in that neighbourhood if further large-scale ironstone working is authorized, and has also sought to preserve the heronry at Chievsley Furze, the famous crocus field at Inkpen, Berkshire, and the sites on which the military and monkey orchids, the red helleborine and the wild fritillarias grow

Museums Journal

THE second issue of the new format of the quarterly *Museums Journal* (61, No 2, September 1961) maintains the high standard and deals with a variety of topics Mr F I. G Rawlins emphasizes the value of the scientific outlook in conservation, Mr Philip Rawson describes the new Gulbenkian Museum in the University of Durham and Mr Robert Hill deals the various types of electronic lecture guide systems which are now proving of such absorbing interest to museum curators Much of this issue is devoted to a record of the annual conference of the Museums Association held at Plymouth in June 1961 A report on the symposium held at the British Museum (Natural History) on "The Museum and the Naturalist", and book reviews, complete an informative issue

The Bernice P. Bishop Museum, Honolulu

Under the title of "Work Half Done" the Bernice P Bishop Museum at Honolulu issues its report for 1960 The title refers to the fact that at the end of 1960 the Museum was in the middle of a particularly important project, the new Planetarium-Observatory. This ambitious building is being constructed without the necessary total of capital funds but with the conviction that these will be forthcoming when the value of the venture is demonstrated An interesting experiment was involved in the trapping of air-borne insects to determine the role of air currents in insect dispersal This was carried out both on board ship and by a special device in aeroplanes

The Stanley Clifford Milk Industry Award

The Central Milk Distributive Committee, in recognition of the valuable services rendered in the dairy industry by Stanley Clifford, who was for many years chairman of the Committee, has established a fund for the purpose of providing awards to enable a suitable applicant to make a short study tour of the dairying industry in the United Kingdom or abroad Employees in the dairy industry or in dairy engineering in the United Kingdom who are below the age of thirty are eligible The Award, which will be made annually, will be administered by the Society of Dairy Technology. It has been decided that the first award shall be granted for a study tour in Denmark immediately following the International Dairy Congress which is to be held in Copenhagen during September 3–7, 1962 Applications for this Award should be made to the Secretary, Society of Dairy Technology, 17 Devonshire Street, London, W 1, not later than January 31, 1962

Royal Institute of Chemistry Lecture Series

The first three numbers of the Royal Institute of Chemistry 1961 series of lectures have just been published (The Royal Institute of Chemistry Lecture Series 1961 London Royal Institute of Chemistry, 1961 5*s* each) The first, entitled *Atmospheric Photochemistry*, is by Sir Harrie Massey and Dr A E Potter, the second, *A Chemist's Introduction to Statistics, Theory of Error and Design of Experiment*, by Dr D A Pantony, and the third, *Recent Developments in Polarography*, is by Dr G W C Milner The booklets also contain a list of other recent publications of the Institute

The Night Sky in November

New moon occurs on Nov 8d 09h 59m U T and full moon on Nov 22d 09h 44m The following conjunctions with the Moon take place Nov 2d 05h, Regulus 0 01° N, Nov 13d 13h, Saturn 3° S, Nov 14d 00h, Jupiter 3° S, Nov 23d 03h, Aldebaran 0 7° S, Nov 29d 13h, Regulus 0 3° S In addition to these conjunctions with the Moon, Venus is in conjunction with Spica on Nov 4d 17h, Venus being 4° N Mercury is a morning star, visible low in the south-east before sunrise, on November 7 it rises almost two hours before the Sun Venus is a morning star, rising at 4h 50m, 5h 30m and 6h 20m on November 1, 15 and 30, respectively It is rather too close to the Sun for convenient observation Mars is too close to the Sun for observation Jupiter and Saturn are evening stars, setting about four hours after the Sun They may be seen low in the south-west after sunset, they are not very favourably situated for observation Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Nov. 20d 16h 56·9m, ξ^2 Cet (*D*); Nov 21d 2h 22 9m, μ Cet (*D*), Nov 23d 2h 52 8m, α Tau (*D*), Nov 23d 3h 44 3m, α Tau (*R*), Nov 24d 4h 23 5m, 119 Tau (*R*) Nov 24d 5h. 07 4m, 120 Tau (*R*), Nov. 24d 21h 14 4m, 71 Ori (*R*); Nov 27d 3h 56 7m, ζ Cnc (*R*), *D* and *R* refer to disappearance and reappearance, respectively The Taurid meteors are active during the first half of the month, maximum activity being on November 7 The radiant is at R A 3h 36m, Dec + 14°, and conditions for observation are favourable The Leonid meteors are active on November 16, the radiant being at R A 10h 08m, Dec + 22°, and conditions for observation are favourable

Announcements

Prof W T Williams, professor of botany at the University of Southampton, has been appointed a member of the Agricultural Research Council in succession to Prof S J Watson, who has retired after ten years service

The one-hundred-and-twenty-eighth meeting of the American Association for the Advancement of Science will be held in Denver, Colorado, during December 26–30 Further information can be obtained from the director of public information, Sidney S Negus, Medical College of Virginia, Richmond, Virginia

An international conference on "Magnetic and Electric Resonance and Relaxation" is to be held at Eindhoven, The Netherlands, in July 1962, under the auspices of the Netherlands Physical Society and the *Groupement Ampère* Further information can be obtained from Dr D J Kroon, Philips Research Laboratories, Eindhoven, Netherlands

The second International Symposium on Continuous Culture of Micro-organisms will be held in Prague during June 18–23, 1962. It is being sponsored by the Czechoslovak Academy of Science Further information can be obtained from Academician Ivan Málek, Czechoslovak Academy of Science, Institute of Biology, Na cvičišti 2, Prague 6, Czechoslovakia

Messrs Macmillan regret that an incorrect price for Volume II of Partington's "History of Chemistry" was given in *Nature* of October 14, p lxxxix, the volume is being published at £5 5*s*. net

Errata Dr D H Trollope has written stating that some omissions and misprints have occurred in the communication entitled "Effective Contact Stresses and Friction" published in *Nature* of July 22, p. 376 Equation 7 should read $R = \frac{W}{N} - ua + \rho a$, equation 8 should read $F_j = \mu\left(\frac{W}{N} - ua + \rho a\right) = \mu\left(\frac{W}{N} - u\frac{A}{N} + \rho\frac{A}{N}\right)$, equation 9 should read $S = \mu(\sigma - u + \rho)$ On p 376, col 2, line 41, for 'macro-fraction' read 'micro friction', line 56, for 'invert' read 'inert'; line 57, for $\mu = 0$ read $u = 0$

SCIENTISTS IN THE PUBLIC SERVICE

SPECIAL PROMOTIONS

As in previous years a number of special posts has been created in the Scientific Civil Service under the provisions included in the White Paper on the Scientific Civil Service (Cmd 6679, 1945) to provide for the promotion of individual research workers of exceptional merit The promotions were effective from July 1 and include the following ·

Deputy Chief Scientific Officers

Dr L J Bellamy, who is superintendent of Analytical Services at the Ministry of Aviation's Explosives Research and Development Establishment, Waltham Abbey, entered Government service in 1939 and undertook various analytical jobs until he was posted to the Directorate of Chemical Inspection, Woolwich, in 1945 Here he became responsible for the development of new methods of analysis, particularly physical methods, and became a member of the World Health Organization Expert Advisory Committee on Insecticides In 1955 he was transferred to his present post, where he has been responsible for the development of new analytical methods, research and assessment on the stability and compatibility of explosives, X-ray and electron microscopy techniques and polymer synthesis and properties Dr Bellamy's major personal contributions have been in the fields of the interpretation of the spectra of large molecules, solvent effects, and more recently on the difference in the associative properties of protons and deuterons. On the interpretation of spectra of large molecules, Dr Bellamy has developed a broad theory, whereby the behaviour of the more important group frequencies can be predicted and understood This has revealed new relationships between frequency shifts and other physical properties On solvent effects, his work has led to a better understanding of inter-molecular forces in solution

Dr. A F Gibson is leader of the Semiconductor Physics Research Division at the Royal Radar Establishment of the Ministry of Aviation at Malvern, and has been associated with that establishment since 1944 Dr. Gibson's work has included luminescence, infra-red photo conductors, transistor physics and research of a fundamental character on the properties of semiconductors He has applied his research to practical needs and has been responsible for the development of a new form of far infra-red and millimetre wave detector, based on cyclotron resonance and an avalanche injection diode of value in fast-switching circuits He has carried out investigations of the microwave properties of germanium and the effect of carrier injection and extraction on the absorption. Dr Gibson's most recent work has been concerned with 'hot' electrons in germanium, which has shown the complex nature of the processes whereby energy given to electrons in a semiconductor by an electric field is exchanged with the lattice to give ohmic heating and how, when this cannot be done sufficiently rapidly, the energy is spread unequally among the various 'valleys' in momentum space Similar investigations carried out with 'holes' have led to a better understanding of the band structure of the complex valency band of germanium

Senior Principal Scientific Officers

Dr J M Burch, of the National Physical Laboratory, specializes in metrological optics, particularly in the production and application of photographic gratings These gratings are of two kinds large photographs of very closely spaced interference fringes for spectroscopic purposes, and gratings for linear and radial measurement based on the improvement of conventional rulings by methods of 'photographic averaging' Gratings, read by optical and electronic methods to which Burch has also made important contributions, are now being extensively used in the control of machine tools and in metrology Dr Burch has recently taken charge of a research project concerned with the development and application of optical masers

Prof J C Cooke, one-time professor of applied mathematics in the University of Malaya, is now working on fluid dynamic theory in the Aerodynamics Department at the Royal Aircraft Establishment, Farnborough

Dr. D A L Davies, attached to the Immuno-Chemistry Section of the War Department's Microbiological Research Establishment at Porton, is concerned with work on the isolation and structure of bacterial antigens. His work has laid the basis for a chemical and immunological approach to tissue-cell antigens

Mr D Firth is now in charge of the work of the Fluid Power Section of the National Engineering Laboratory concerned with research into oil hydraulic and pneumatic devices for general industrial use Earlier this year Mr Firth won the Wolfe Award for his work on hydrostatic transmissions.

Mr J F Gittins, of the Services Electronics Research Laboratory Extension, run by the Admiralty at Harlow, has undertaken research in the field of high-power microwave valves, particularly of the travelling-wave variety This has led to the use of the travelling-wave tube as an effective high-power amplifier at microwave frequencies Mr Gittins is also chairman of the Power Valve Research Advisory Panel of the Co-ordination of Valve Development Committee

Mr B E J Pagel is in charge of the Astrophysics Department at the Royal Greenwich Observatory In addition to carrying out theoretical and observational research Mr Pagel has also assisted in the design of new apparatus and introduced improved techniques

Dr G B Preston, of the Royal Military College of Science, Shrivenham, has been engaged in research in the field of pure mathematics, particularly in the theory of semi-groups

Dr J T Stuart, of the Aerodynamics Division, National Physical Laboratory, has made contributions to the study of the stability of fluid flow Of particular significance is his research work into the non-linear theory of hydrodynamic instability, the growth of wave disturbances and the effects of Reynolds stresses on transition from laminar to turbulent flow

Dr R H Wood is in charge of that part of the Building Research Station research programme that deals with structural engineering design problems; his particular interest is the structural interaction between the various elements of construction in multi-storey framed buildings. This interaction, or mutual stiffening of the parts of a building so as to strengthen the whole, has an important influence on building design, and Dr. Wood's work has contributed greatly to the understanding of the structural behaviour of complete buildings and to the more efficient allowance for composite action in structural design.

Similar promotions have been made by:

(1) United Kingdom Atomic Energy Authority: Senior Principal Scientific Officers

Mr. J. C. Martin has worked at the Atomic Weapons Research Establishment, Aldermaston, since its foundation in 1953. His early work was concerned first with small-scale explosives research, investigating the motion of fluid surfaces and later with the development and use of scintillation counters. More recently he has worked on neutron sources and on the development and application of sub-microsecond radiographic techniques for the experimental work on explosions. Starting with an early prototype 35-MeV. linear accelerator for which he developed a double focusing system, he has brought it to a state of output and reliability which has made it a valuable tool in the solution of certain hydrodynamic problems. He is now attempting to extend the flash X-ray technique from its present limit in the region of 1 MV. up to about 6 MV. He has contributed a number of original ideas in the field of advanced nuclear and thermo-nuclear weapons.

Dr. J. B. Taylor has worked at the Atomic Weapons Research Establishment, Aldermaston, for six years. He contributed first to the improvement of neutronic calculations used in the theory of explosions and in the computation of the stochastic behaviour of small populations in a supercritical system. He then carried out a number of investigations, ranging over several fields and at all levels of detail, to illuminate and help to direct the astrophysical engineering behind the megaton test series of 1957–58. He later worked on problems connected with fast reactors and on electromagnetic phenomena from explosions, before turning to problems of the thetatron and other controlled thermonuclear reactors.

(2) Agricultural Research Council: Deputy Chief Scientific Officer

Dr. R. Markham joined the staff of the Plant Virus Research Station, Cambridge, now the Agricultural Research Council Virus Research Unit, in 1940 and became director of the Unit in 1960. His research has been concerned mainly with the biochemistry of the smaller plant viruses, and in 1949 he was able to demonstrate that the ribonucleic acid of the turnip yellow mosaic virus, which he and Dr. Kenneth Smith first isolated and purified, was necessary for the infectivity of the virus and was enclosed in a protective shell of protein. This work led to an intensive investigation of nucleic acids in general and resulted in the development of a large number of delicate methods for the analysis of nucleic acids and their constituents. It also led to an understanding of the way in which some of the enzymes which degrade nucleic acids, particularly pancreatic ribonuclease, act. Dr. Markham has also been concerned with synthetic mechanisms by which small polynucleotides can be made. He was elected a Fellow of the Royal Society in 1956.

Senior Principal Scientific Officers

Dr. C. H. Cadman is head of the Virology Department, Scottish Horticultural Research Institute, Mylnefield, Dundee, and is at present particularly concerned with the transmission of plant viruses by nematodes.

Dr. B. **Kassanis**, of the Plant Pathology Department, Rothamsted Experimental Station, has discovered and described a number of viruses, and recently discovered that the multiplication of the virus depends on the simultaneous multiplication of another.

Dr. A. **Kleczkowski**, of the Plant Pathology Department, Rothamsted Experimental Station, is primarily a serologist, but has made substantial contributions to a range of subjects, and is now studying the surface structure of the protein units which make up tobacco mosaic virus.

THE ROYAL SCOTTISH MUSEUM

By Dr. D. A. ALLAN, C.B.E.

Formerly Director

THE foundation stone of the Royal Scottish Museum was laid by the Prince Consort in October 1861, and thereafter there arose in instalments the Venetian Renaissance building which now occupies more than half of Chambers Street, west of the Old College, University of Edinburgh. It is a grey stone structure consisting of a central block elongated east and west, with two wings stretching southwards. The area within was afterwards built on to yield a series of rectangular halls, most of them with a main ground-floor surmounted by two balconies, the earlier ones supported on cast-iron pillars, the later either cantilevered or upheld by ferro-concrete structures. A 'grand staircase' was added at the rear in 1931, with arches at its mezzanine landings to lead to a prospective future block. A lecture hall had been included in the earliest part of the building but was later sacrificed to yield much-needed exhibition space, yet the necessity for a hall for lectures and demonstrations and later to provide educative film shows was ever present, and just before the Second World War foundations were dug beyond the 'grand staircase' for a rectangular lecture hall . . . and were left to be obliterated by ashes from the boilers. In May 1959 work was commenced on a theatre block of an entirely novel design, and its completion was achieved early in September 1961, the opening ceremony being performed by the Right Hon. the Earl of Rosse, chairman of the Standing Commission on Museums and Galleries, with the Right Hon. John Scott Maclay, H.M. Secretary of State for Scotland, in the chair.

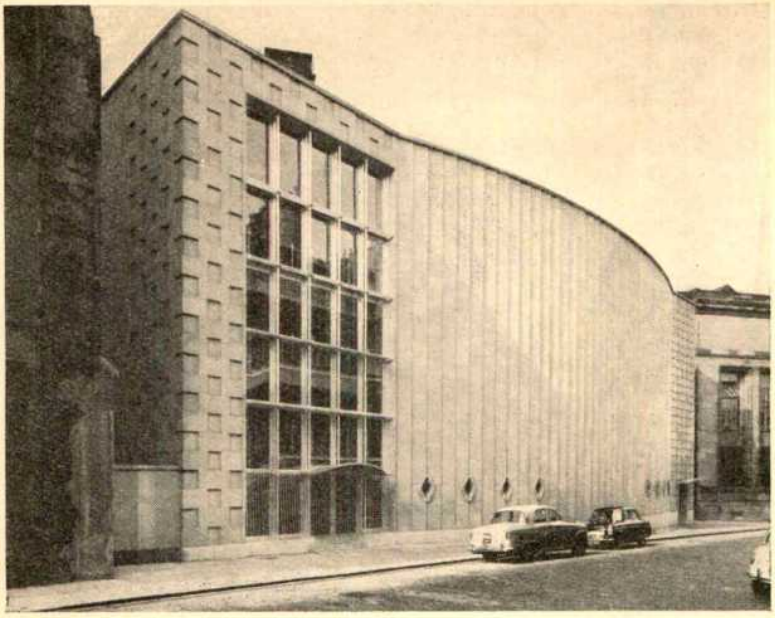

Fig. 1. The Royal Scottish Museum, New Theatre Block

The site was a difficult one, being a triangle hemmed in by part of the back of the old building, a busy street and a little cul-de-sac. Again, whatever occupied it had to marry with a 1914 red sandstone somewhat classical façade of the Museum zoological galleries beyond and the grey sandstone of the Robert Adam Old College building further on.

The principal contribution being a lecture theatre, it had to be given the lion's share of the space, and the angle of the seating floor was determined by the number of persons to be accommodated. As the Museum's opening ceremonies attract around 200 guests—and the early 1900 public lectures, organized by the Museum but housed in the adjacent University examination hall, as many as 250—it was determined that the new theatre should hold 300. The plans allowed for this number of seats in ten curving rows of thirty, rising steeply on steps, with three aisles. The platform is low, long and narrow, so that everyone can have an uninterrupted view of speaker, demonstrations or of the screen occupying the central portion of the wall beyond. The back of the auditorium is against a solid bow-shaped, windowless street wall, impervious to light and sound. At the narrowing end of the triangle is an emergency staircase, with a side door at street-level. The wider end of the triangle is a three-storeyed block, each floor consisting of a curving chamber running from the street back to the older part of the building. The ground-floor is a foyer with a door to the street, another to the main museum building and the double sound-proof doors to the front of the auditorium. Above are two more floors, reached by an open staircase of steps cantilevered on a single supporting beam, with landings against an immense window rising the height of the building and facing the street. Because of differences in level, the foyer is broken across the middle and a short flight of curving steps leads from the new end to the old. The top-floor gallery opens on to an extensive exhibition hall over the lecture theatre, top lit and with an additional exit to the top of the emergency staircase. The proportions of the building can be put briefly and roughly—two-thirds width and two-thirds height for the lecture theatre, with the remaining third at the top exhibition hall and the remaining third at the side foyer with two overlying exhibition rooms. Underneath is a large cellar space, which will later be developed to advantage for much-needed storage. In contrast to the prevalence of right angles throughout the many halls of the old building, those in the new are limited to the contacts between floors and walls and walls and ceilings.

The lecture hall, which will be used for opening ceremonies connected with special exhibitions in the adjacent halls, conferences, lectures, school-class talks and cinema shows, presents a novel, modern and entirely charming interior, with its major sweep across its width, and the steeply tiered rows of tip-up chairs, upholstered in grey plasticized fabric, flanked and backed by walls lined to the full height with *Abura* wooden strips of a warm brown colour. The ceiling, which is also acoustically designed, presents a pattern of shallow rectangles in relief to the audience but projects a battery of lights from the unseen forward and downward projecting ends on to the platform. The lighting can be controlled either from the stage or from the projection room in the rear of

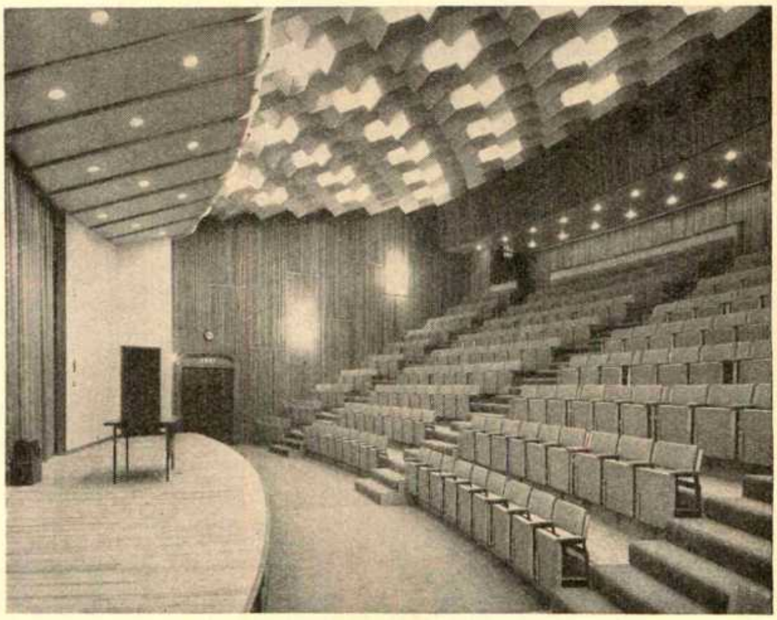

Fig. 2. New Lecture Theatre, Royal Scottish Museum

the ceiling. The tiers and access gallery at the back are covered in grey marbled plastic flooring, with gold-coloured carpet on the three access stairways and blue carpet fronting the stage, the curtains of which are in gold. Hardwood strip has been used in the floors of the exhibition halls and travertine for the foyer. The 'flying' staircase is finished with hardwood treads with rubber inserts and aluminium; plate glass and plastic have been used for the balustrade. The architect has designed an appropriately carved teak door for the emergency exit. The designs begin at the base with early forms of life and fossils, pass up to various animals and man, show locomotives, telephones and television sets, and lead to a top row of aeroplanes, sputniks and an atomic explosion. The 'finale' is a row of question marks.

The exhibition halls are heated by low-pressure water coils contained within the floor. Background heating for the theatre is provided by coils behind the stage front and this will be supplemented when the hall is in use by warmed air introduced through the slats on the walls near the stage and extracted at the ceiling below the projection room. The 16-mm. projector is sited in a special room reached by a passage above and behind the auditorium. The building could well have taken a full-size projector, but in view of the difficulty of getting documentary films suitable for educational purposes, the smaller size had to be chosen.

The façade of the new extension is spectacular and modern, yet it provides a pleasing gradation with its neighbours. The bastion-like central mass consists of plain ribs of cream-coloured sandstone, reminiscent of a clinker-built boat, and standing on a simple polished granite base. In the lower portion of the sandstone are a few ovoid windows.

The curved central mass is flanked by two unequal flat walls, that to the east being smaller and having its square sandstone blocks split into two facets angled diagonally, so as to yield an attractive shadow pattern. The greater flank to the west is framed in square sandstone blocks with alternate ones set back to provide a different pattern, but the main face is a rectangular aluminium frame with a slightly arched doorway in the centre surmounted by five tiers of plain glass panes, the horizontal crossings marked by narrow bars which combine decoration with utility in supporting window cleaners. Through the glass, the stair landings add a decorative motif. The architect was Stewart Sim, a senior architect of H.M. Ministry of Works, and the contract was carried out by Thaw and Campbell, Ltd., Glasgow, at a cost of approximately £120,000. Thus the Royal Scottish Museum displays the march of time in its architecture and its furnishings—in its exhibits as well—over a full century.

CANCER RESEARCH IN THE UNIVERSITY OF PERUGIA MEDICAL SCHOOL

By Prof. LUCIO SEVERI
Director

On June 26, the occasion of the centenary celebrations of the chair of morbid anatomy of the University of Perugia, Dr. Thelma B. Dunn, head of the Cancer Induction and Pathogenesis Section, National Cancer Institute (U.S.A.), opened at Monteluce an extension to the Division of Cancer Research, University of Perugia Medical School.

The ceremony included a visit to the new animal-house and the remodelled older one, on the main floor, in which normal work was in progress. The guests consisted essentially of the participants of the international conference on the "Morphological Precursors of Cancer". At the opening of the extension, all the doctors *honoris causa* of the University of Perugia Medical School were present, including Prof. A. Haddow, director of the Chester Beatty Research Institute, London; Prof. J. W. Orr, director of the Department of Pathology and Cancer Research Laboratories, University of Birmingham; Prof. J. J. Bittner, Division of Cancer Biology, University of Minnesota, Minneapolis; Dr. L. C. Strong, director of the Biological Section, Roswell Park Memorial Institute, Springville; Dr. J. R. Heller, president of the Memorial Sloan–Kettering Cancer Center, New York; Prof. C. Krauspe, director of the Institute of Morbid Anatomy, University of Hamburg; Prof. V. R. Khanolkar, vice-chancellor of the University of Bombay; and Prof. T. Yoshida, dean of the Faculty of Medicine, University of Tokyo.

The extension was designed by Prof. G. Nicolosi, Rome, and the work was carried out under the direction of Dr. G. Castori, Perugia, being erected by Messrs. Fioroni, Perugia, at a cost of 50,000,000 lire. The new accommodation doubles the previous floor area and makes the Division the largest and best equipped organization of its kind in Italy.

The extension consists of four storeys of concrete-cased steel-framed structure, faced with grey-coloured plaster. The various floors are formed with pre-cast concrete flooring units. The various services to the laboratories, which include hot and cold water, gas, electricity, compressed air, vacuum and steam, are visible, not concealed. In this way easy access is possible to the various services and pipe-lines when it is desired. Each floor is served by an automatic electrically operated passenger lift. The new building is linked with the older Division of Cancer Research by an underground passage, and contains extensive animal-house accommodation and laboratories for virology, tissue culture and cytogenetics.

The main financial responsibility of the Division of Cancer Research has always been borne by the University of Perugia. Additional funds are provided by the National Cancer Institute of the U.S. National Institutes of Health, and to a lesser, but valued, extent from the Lega Italiana per la Lotta contro i Tumori, Consiglio Nazionale delle Ricerche, Farmitalia Milano, and from other private Italian benefactions.

It is only since the Second World War that the idea of a Division of Cancer Research in the University of Perugia was conceived. But it was several years before the plan could be carried out. On November 30, 1952, the Minister of Public Education, on the occasion of the opening of the academic year, announced the establishment of a University Division of Cancer Research at Perugia. In the first building were established an animal

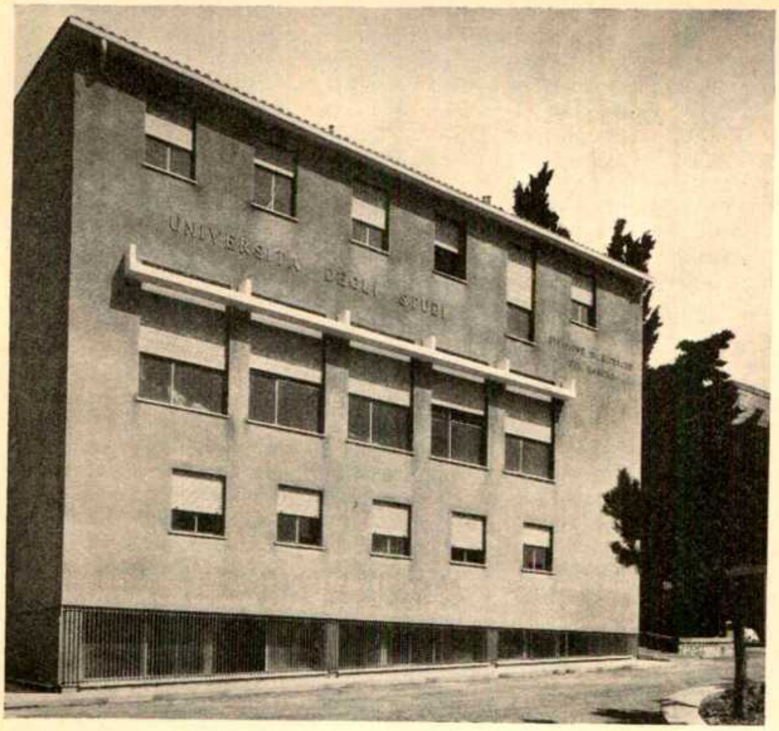

Fig. 1. New Extension of the Division of Cancer Research, University of Perugia Medical School

colony and laboratories for research in biology and pathology. Later, in the years 1956 and 1957, a programme of improvement was completed with the aid of grants and contributions.

During recent years, investigations have been carried out in the Division by various groups of scientists on different aspects of cancer research. Work on the spreading of metastases in human and experimental tumours has been described in a series of papers dealing with the various facets of the problem. A valuable contribution to the conflicting problems of the morphological precursors of human breast cancer was made by the staff of the Division of Cancer Research working as a unit. In the initial phase, different types of mammary cancer, arising from different lesions, and characterized by a different age at onset, ætiological pattern and morphology were detected and classified. It was then shown that the frequency and the latency period were also different for each of these types of cancer. On this basis, an attempt was made to determine the order of importance of the respective morphological precursors; this is still regarded as a useful factor for prognosis.

In recent years, much effort has been transferred to the study of causation, behaviour and evolution of mammary tumours in inbred mice. The origins, nature, fate and hormonal control of the hyperplastic alveolar nodules in the mammary glands of virgin and breeding animals carrying the milk factor have been analysed in a series of papers. After the discovery of a new kind of pre-malignant change, the plaque, in hybrid animals, various inbred strains of mice normally bred were investigated to determine the occurrence of plaques. These have been found in two of the three strains investigated. In connexion with these experiments, an analysis of responsiveness and progression of mammary tumours of inbred mice was carried out, which led to the detection of the existence of strain differences in the biological and morphological characters of neoplasms. Finally, a recent extension of these investigations has shown that the strain differences found might be due to differences in the properties of the respective milk factors.

A new field of investigation, cytology, opened at the Division of Cancer Research with the conversion of a spontaneous mammary tumour into an ascites tumour. Work on the mitotic rate and chromosomal pattern of this ascites tumour is now in progress.

Recently, it was demonstrated that isoniazid, a drug very widely used in the management of tuberculosis, is carcinogenic for the lungs of *BALB/c* mice. Due to its practical importance, this field of investigation has been rapidly extended in order to see whether isoniazid is carcinogenic to other species of animals, whether it is carcinogenic in itself or through some of its metabolites, and how this carcinogenic action may be prevented.

Since its foundation, the Division of Cancer Research has encouraged, within the limits of its facilities, visits of qualified scientists from foreign countries, in order to exchange information and ideas on the work in progress. A large number of such visitors have come during recent years. Several of them delivered lectures. For others, small seminars were organized with the staff. Other visiting scientists have spent several months working at the Division of Cancer Research with members of the staff, in fields of common interest.

THE INTERNATIONAL FEDERATION FOR DOCUMENTATION

THE twenty-seventh conference of the International Federation for Documentation was held at Caxton Hall, London, during September 6–16. The Federation has its headquarters at The Hague, and its work on many different problems of documentation is carried on mainly through correspondence, committees and meetings of the Executive Bureau and a General Assembly held each year in a different country. The large, unrestricted, conference gatherings take place only every three or four years and this was the first to be held in England since 1938. It was attended by more than 500 delegates coming from 38 countries and from all five continents. Aslib, as the British representative body in the Federation, was responsible for the arrangements

The earlier part of the conference, that is, during September 6–11, was devoted to meetings of committees, the Executive Bureau, and the General Assembly with a special session on September 9 to consider present-day systems and trends in automatic documentation such as the use of electronic computers and research into the possibilities of mechanical translation Excursions to Oxford and Cambridge were arranged for September 10

During the second week of the conference, an exhibition of new processes and experimental work in documentation was open, and included a device for the automatic identification of printed numerals demonstrated by Dr M B Clowes and Mr J R Parks of the National Physical Laboratory

The official opening of the full conference took place on September 12 when the Baroness Wootton of Abinger, deputizing for Lord Hailsham, Minister for Science, gave the opening address The chairman, Dr Burton W Adkinson, head of the Office of Science Information, U S National Science Foundation, referred to the great loss to the Federation through the recent death of Fritz Donker Duyvis His passing had been "the quiet closing of a door on an age", the age of the pioneers of documentation such as Otlet and La Fontaine, and of the devoted amateurs who followed them such as "D D " who, for more than two decades, was the embodiment of the International Federation for Documentation After this tribute to the late secretary-general of the Federation, the meeting heard four papers describing recent developments in documentation These were presented by Dr K Schneider (Germany), who described the use of electric typewriters operated by punched cards, Mr A C van Schaik (Netherlands), who showed that advantages could come through bibliographical co-operation within a country, Mr C W Cleverdon (United Kingdom), who outlined the work of the Aslib Cranfield investigation into the efficiency of indexing systems, and Mr Karl F Heumann (United States), who presented Verner W Clapp's summary of recent important progress in documentation in the United States In the evening delegates attended a reception given by the Vice-Chancellor of the University of London and Mrs Noble at the Senate House

The morning sessions of September 13 dealt with scientific and technical information under the chairmanship of Dr M A T Rogers, research controller, Imperial Chemical Industries, Ltd , deputizing for Dr T E Allibone, who was indisposed Papers were contributed by Mr R G l'Hermite (France), Dr A Moore (United States), who dealt particularly with the problem of information in the pharmaceutical industry, and Dr Y Niwa, who described the history and growth of the Japan Information Centre of Science and Technology and similar services in his country

The afternoon session was presided over by Mr G Deurinck, of the Fondation Industrie-Université pour le Perfectionnement des Dirigeants d'Enterprises, Belgium The papers covered the documentation of management (Prof R W Revans, United Kingdom, and Prof J L Mey, Netherlands), and the use of information for economic planning (Mr K Havlíček, Czechoslovakia) In the evening delegates were invited to a reception given by Imperial Chemical Industries, Ltd , at Imperial Chemical House, Millbank

The efficient use of information was the theme of the morning session for September 14 when the chair was again taken by Dr Burton W Adkinson Mr R. E McBurney described the work of the Canadian Technical Information Service of the National Research Council Mr K Klintoe, director of the Danish Technical Information Service, spoke on productivity in information service, Mr William T Knox gave an interesting talk on the use by some United States companies of senior scientists or engineers as information research workers, and Mr J de Laclémandière (France) set out his views on information and the 'law of least effort' The afternoon was left free for visits and other activities and in the evening a reception was held by H M Government in the unique setting of the King's Library, British Museum, when Lord and Lady Hailsham received the guests

The final public session and the official closure of the conference took place on the afternoon of September 15, with Dr Alexander King, president of the Federation. in the chair The General Assembly this year had been attended by representatives of twenty-four member countries and by observers from several other regions Dr King welcomed the presence of Miss Hilda S Lindstedt, formerly librarian of the Royal Technical University, Stockholm, and now an honorary member of the Federation Dr King went on to say that the decision to break away from tradition and to hold the 1960 meetings at Rio de Janeiro had had important consequences for the International Federation for Documentation, including some changes in constitutional procedure In future, presidents would be elected a year in advance of the date on which they would take office and retiring presidents would serve an additional year as members of the Executive Bureau, all this made for continuity

Dr King announced that Dr Burton W Adkinson would succeed him as president in 1962 Vice-presidents were working appointments chosen on a regional basis The vice-presidents for Western Europe were now Miss Barbara Kyle (United Kingdom), Dr Z Paulo (Portugal), Dr W Schurmeyer (Germany) and Prof E Wegelius (Finland). East European vice-presidents were Dr L Janzky (Hungary) and Prof A I Mikhailov (U S S R) Dr S R Ranganathan (India) had retired and his place had not yet been filled, but Far Eastern representation was in the capable hands of Prof H. Ootuka (Japan) For the Americas, Mr K. F Heumann (United States) would replace Dr Burton Adkinson, now president-elect, and Prof Lydia Sambaquy (Brazil) would continue in office

Turning to future conferences, Dr King announced that the meeting for 1962 would be at The Hague It was hoped that a meeting in one of the Asian countries could be arranged for 1963 or 1964, and the United States had issued an invitation to hold the next unrestricted conference in Washington in 1965

Dr King then dealt with the committees, the secretariats of which were now each located in different member countries Mr E Ohman (Sweden) had been appointed the first full-time officer of the Universal Decimal Classification at The Hague The training of personnel for carrying out documentation was being actively investigated under Prof Majewski at Warsaw, a newly constituted committee to consider the theory of classification would be based in Denmark, responsibility for linguistic problems had been accepted by the Netherlands, and mechanized documentation was the special concern of the German section. A new *ad hoc* Committee had been set up to give an impartial study to the future of the Universal Decimal Classification.

For the closing moments of the conference Dr. Burton Adkinson took over the chair and voiced the thanks of the delegates to the representatives of the host country, and in particular to Aslib, for the organization of the conference and for the accompanying programme of visits and entertainment.

E. M. R. Ditmas

X-RAY MICRO-ANALYSIS

List 177/2, recently issued by the Cambridge Instrument Co., Ltd., is an illustrated booklet* giving a comprehensive description of the Company's 'Microscan' X-ray analyser which is now in production. The technique of X-ray micro-analysis consists of focusing an electron beam, normally accelerated from 0 to 50 kV., on to a region of the surface of the specimen, approximately 1μ in diameter and rather less in depth, and analysing spectroscopically the resulting X-rays excited from the specimen. R. Castaing, in 1951, published details of the first practical instrument that could be described as an 'emission' micro-analyser, but Castaing's instrument, in common with similar instruments developed independently by others, used a static electron probe; it was thus limited to carrying out only point-by-point micro-analyses on parts of the sample surface previously selected under an optical microscope. The Cambridge instrument incorporates a deflexion system to control the electron probe, and in addition to static point-to-point micro-analyses it can also be used for scanning a maximum area of about $\frac{1}{2} \times \frac{1}{2}$ mm.^{2} on the sample surface. It is based on the instrument originally designed by Dr. D. A. Melford and colleagues at the Tube Investments Research Laboratories in collaboration with Dr. V. E. Cosslett and Dr. P. Duncumb, who were responsible for the prototype developed at the Cavendish Laboratory, University of Cambridge.

In the booklet the arrangement, constructional details and functioning of the analyser are clearly set out, together with photographs of parts of the instrument and of results obtained with the instrument. The analyser consists of four separately standing sections—the electrical supply unit, the main console, and three racks occupied mainly by scanning, counting and display electronic equipment, respectively. In the main console are housed the vacuum system consisting principally of a 2-in. oil diffusion pump backed by a rotary pump, the electron-optical system, the specimen chamber on which the electron-optical system is mounted and which is designed to allow from outside the maximum possible manipulation of the specimen which is itself under high vacuum. Sixteen positions are provided on the table and the table can be rotated to bring any one of the positions under either the electron beam or the optical microscope, the binocular optical microscope for conventional optical examination of the specimen for comparison with the electron image, and the semi-focusing X-ray spectrometer of a special and simplified design, containing three curved, rotatable, lithium fluoride crystals and two interchangeable detectors, one a sealed-off proportional counter for the detection of hard radiations and the other a flow proportional counter for soft radiations.

The technique of X-ray micro-analysis has so far been successfully applied to investigating the micro-structure of both metals and minerals, and although the 'Microscan' was designed primarily for metallurgical work it can be used for substances other than metals. By providing both X-ray and electron pictures of small surface regions, the analyser is invaluable as a metallurgical tool, and the examples of its application to the examination of various alloys and inclusions in steel which are discussed and illustrated in the booklet show clearly its advantages. Its main limitation, in common with other similar instruments, is its inability at present to detect the soft X-rays from specimens consisting of elements of atomic number less than twelve.

DISTRIBUTION OF INTENSITY AMONG VARIOUS ULTRASONIC DIFFRACTION ORDERS

By Dr. C. RAGHUPATHI RAO
Department of Physics, Nizam College, Hyderabad

The generalized theory of Raman and Nath gives very complicated expressions which, with certain restrictions, have been modified by Nath[1] to get closed expressions for intensities of ultrasonic diffraction orders. The intensity of the supersonic field is assumed to be not strong enough to excite the second and higher orders and solving the difference-differential equation obtained in the generalized theory, the following expressions for the intensities of the first and central zero orders have been obtained for normal incidence:

$$I_1 = \frac{4}{\rho^2 + 8} \sin^2 \left\{ \frac{\sqrt{\rho^2 + 8}}{4} \xi \right\}$$

$$I_0 = 1 - \frac{8}{\rho^2 + 8} \sin^2 \left\{ \frac{\sqrt{\rho^2 + 8}}{4} \xi \right\} \qquad (1)$$

where $\rho = \frac{\lambda^2}{\omega\omega_0\lambda^{*2}}$ and $\xi = \frac{2\pi\omega L}{\lambda}$

This expression clearly reveals that the intensity of the zero order I_0 on diffraction is less than unity by a value of $2 \times I_1$ where I_1 is the intensity of the first order of diffraction. The intensity of the zero order is shared by the two first orders of diffraction equally on either side of the central order. If the individual intensities of various orders, I_0, I_{+1} and I_{-1} could be measured accurately, then it can be expected, according to expression (1), that the sum of the three intensities, that is $(I_0 + I_{+1} + I_{-1})$, should be equal to the original slit intensity I of the zero order without diffraction. With the view of verifying the above statement, intensities of the various diffraction orders were measured with a sensitive photomultiplier tube and the results obtained are presented here.

It is very important to note that only the first orders of diffraction are excited, since expression (1) ignores the intensity of higher orders. Further, when second and higher orders are excited, multiple diffraction effects set in and these are carefully avoided in the present experiments using very low acoustical power.

Table 1 INTENSITY DISTRIBUTION AMONG VARIOUS ORDERS (f = 3·8 Mc/s—normal incidence)

Liquid	I_0/I (per cent)	I_{+1}/I (per cent)	I_{-1}/I (per cent)	Aggregate intensity as percentage of incident intensity
Water	93·9	1·1	1·1	96·1
Acetone	96·6	1·6	1·6	99·8
Methyl alcohol	98·0	0·6	0·6	99·2
Toluene	97·2	0·7	0·7	98·6

A progressive wave in water at 3·8 Mc/s is set up and the intensities of I_0, I_{+1} and I_{-1} on diffraction and the intensity I of zero order without diffraction are measured with the photo-tube. The intensity of the diffraction order expressed as a percentage of the original slit intensity of the zero order is tabulated in Table 1 using different liquids. Table 1 clearly shows that the aggregate intensity of various diffraction orders compares very well with the intensity of the original incident light in the zero order. These experimental results are in good agreement with expression (1).

The second aspect of interest is to study the distribution of intensity among various ultrasonic diffraction orders with obliquity of the sound wave-front. Raman and Nath[2], starting from very simple elementary considerations, have shown that diffraction effects disappear periodically, whenever the obliquity Φ of the sound wave-front from the position of normal incidence is equal to $\tan^{-1}\frac{n\lambda^*}{L}$, where $n \neq 0$ is an integer, λ^* is the sound wave-length in the medium and L is the length of the ultrasonic path traversed by the light beam. The expression for the relative intensities is given by $\frac{J_m{}^2(V)}{J_{n^2}(V)}$ where

$$V = V_0 \sec\Phi \frac{\sin\left(\frac{\pi L}{\lambda^*}\tan\Phi\right)}{\pi L/\lambda^* \tan\Phi} \qquad (2)$$

$$\text{and} \qquad V_0 = \frac{2\pi\omega L}{\lambda}$$

The behaviour of the above expression explains very well the variation of intensity with Φ among various diffraction orders and it is interesting to study this phenomenon with the photo-multiplier.

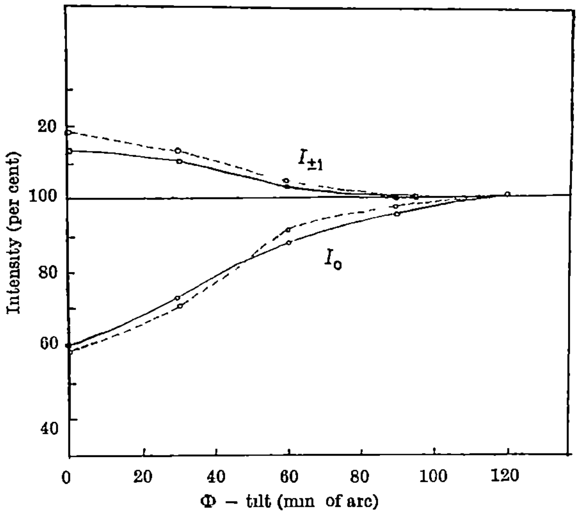

Fig. 1. Variation of intensity of the diffraction orders with obliquity of the sound wave-front

——, Experiment, - - -, theory, f = 3·8 Mc/s, L = 1·5 cm

As before, a progressive wave in water at 3·8 Mc/s is employed and, using moderate power, only the first orders of diffraction on either side of the zero order are excited. The intensities of I_0, I_{+1} and I_{-1} are recorded with the photo-tube for various angles of obliquity Φ in steps of 30′. The value of the parameter V is calculated for the angles of tilt Φ chosen using the expression (2) and the corresponding intensities are evaluated using the Bessel functions $\frac{J_m{}^2(V)}{J_n{}^2(V)}$. The value of L used here is 1·5 cm. The theoretical results evaluated in this way and the experimental ones obtained by the photo-tube for I_0 and $I_{\pm1}$ are plotted in Fig. 1. It can be seen that the agreement between the two curves is very satisfactory, showing the validity of expression (2). The intensity I_{+1} becomes zero at 95′, as can be seen in Fig. 1, and this value compares very well with the angle of 92′ computed by $\tan^{-1}\frac{\lambda^*}{L}$ for the disappearance of the first order.

Expression (2) is very important in that it can predict the poor intensities of the very high frequency diffraction orders observed by several investigators[3,4]. It is well known that at moderately high frequencies, the sound wave-front is to be tilted with respect to the light beam to make the first-order diffraction line appear and therefore the tilt angle Φ is to be taken into account in estimating the intensity of the high frequency diffraction orders. The expression (2) can be written as $V = V_0 \sec\Phi \frac{\sin t}{t}$ where $t = \frac{\pi L \tan\Phi}{\lambda^*}$.

The parameter V_0 in the case of normal incidence is given by $V_0 = \frac{2\pi\omega L}{\lambda}$ and does not include λ^*. But the moment the light beam is tilted, as in the case of high frequencies, the parameter V includes not only V_0 but also λ^*, the sound wave-length in the medium. It is important to see how Φ affects V. The value of Φ involved experimentally is generally small, namely,

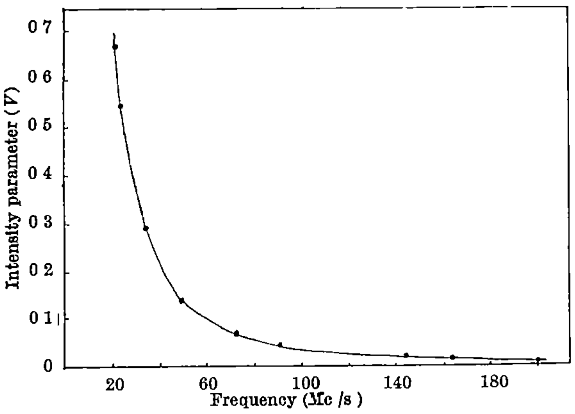

Fig 2 Behaviour of the intensity parameter with increasing frequencies $L = 1\ 5$ cm

< 2°, and therefore one can approximate tan Φ and sin Φ to Φ and write $t = \frac{\pi L \Phi}{\lambda^*}$ But sin t is never equal to t under the experimental conditions since t involves $\frac{\pi L}{\lambda^*}$, which is very large At high frequencies $\frac{L}{\lambda^*}$ tends to increase as λ^* decreases with increasing frequencies, t therefore assumes large values making sin t approach its maximum value unity at very high frequencies Under these valid approximations, the parameter V can be written as $V = V_0/\pi L \left(\frac{\lambda^*}{\Phi}\right)$ and is directly proportional to $\left(\frac{\lambda^*}{\Phi}\right)$ At high frequencies, Φ approaches the Bragg angle[5] to bring the diffraction order into the field of view and λ^* decreases, with the result the ratio $\frac{\lambda^*}{\Phi}$ tends always to decrease with increasing frequencies Therefore the intensity parameter V goes on diminishing with high frequencies as shown in Fig 2, thus giving a natural explanation to the poor intensities observed in high-frequency ultrasonic diffraction phenomena

EIGHT-CO-ORDINATE DIARSINE COMPLEXES OF QUADRIVALENT METAL HALIDES

By Dr. R. J H CLARK, Dr JACK LEWIS, Prof R S. NYHOLM, F R S ,
Dr PETER PAULING and Dr G. B ROBERTSON

William Ramsay and Ralph Forster Laboratories, University College, Gower Street, London, W C I

As part of a systematic study of the ditertiary arsine complexes of transition metal halides, we have been investigating the behaviour of titanium, zirconium and hafnium tetrachloride with the chelate group *o*-phenylene*bis*dimethylarsine[1] (diarsine or *D* in the following account)[1] The ditertiary arsine complexes of metals in the first half of the transition series have been little investigated One reason for this is undoubtedly the great interest in transition metals which have potential double-bonding capacity such as nickel, palladium and platinum In addition, the metals at the beginning of each transition series were thought to co-ordinate with the more electronegative donor atoms such as oxygen rather than with arsenic Provided that one uses a non-hydroxylic solvent as the reaction medium, however, these transition metals will co-ordinate with the diarsine

We have prepared a mono-chelate derivative of titanium tetrachloride with the formula $TiCl_4$ diarsine by the reaction of titanium tetrachloride with the diarsine in 1 1 molar ratio in carbon tetrachloride solution[2] The composition of this compound has been confirmed by analysis and some of its properties are given in Table 1 It is a non-conductor in nitrobenzene solution , it is considered to be a typical octahedral non-electrolyte but it is not iso-structural with $SnCl_4$ diarsine originally described by Allison and Mann[3]

From the reactions between the diarsine and zirconium tetrachloride and hafnium tetrachloride in acetone, we have isolated only the *bis*-diarsine compounds $ZrCl_4$.2diarsine and $HfCl_4$ 2diarsine The corresponding *bis*-diarsine titanium tetrachloride complex $TiCl_4$ 2diarsine can be prepared by treating $TiCl_4$ diarsine with excess diarsine or by a curious reaction between titanium trichloride and the diarsine in glacial acetic acid[2] The reaction of vanadium tetrachloride with the diarsine in carbon tetrachloride solution gives VCl_4 2diarsine This compound is paramagnetic, with one unpaired electron, as expected Some properties of these four *bis*-diarsine complexes are shown in Table 1 They are iso-structural as shown by X-ray powder photography and have nearly identical infra-red spectra

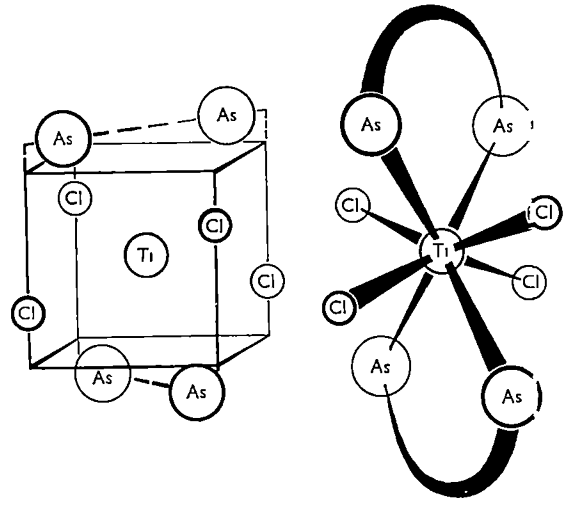
The *bis*-diarsine titanium complex, which is slightly soluble in nitrobenzene, has been more fully investigated than the other derivatives because they have much lower solubilities in all solvents tried In nitrobenzene, $TiCl_4$ 2diarsine forms a non-conducting solution , this implies that in solution either (1) the complex involves an eight-co-ordinated titanium atom, the diarsine behaving as a chelate group , or

Table 1 Properties of Ditertiary Arsine Complexes

Compound	Colour	Melting point in deg (decomp)	Conductivity in nitrobenzene		
			Concentration (mol cm $^{-3}$)	Λ_m (cm ^{2}ohm^{-1} mol^{-1})	μ_{eff} (B M)
$TiCl_4$ *D*	yellow-orange	210	$5\ 0 \times 10^{-3}$	0 5	0 0
$TiCl_4$ 2*D**	orange-red	174	$2\ 3 \times 10^{-3}$	0 9	0 0
VCl_4 2*D**	orange	134	—	—	1 8
$ZrCl_4$ 2*D**	white	290	—	—	0 0
$HfCl_4$ 2*D**	very pale pink	284	—	—	0 0

* Isostructural *D* = diarsine

Satisfactory analytical results for carbon, hydrogen, chloride, arsenic and metal have been obtained for these compounds



(a) (b)

Fig. 1. (a) Drawing showing the relationship between the co-ordination polyhedron and a cube; (b) a perspective view of $TiCl_4$ 2diarsine in which the phenyl rings are represented diagrammatically

(2) the complex dissociates, forming, for example, one mole of $TiCl_4$ diarsine and one mole of free diarsine. (We consider that the possibility that the titanium atom is six-co-ordinate with the diarsine behaving as a monodentate group is excluded by the infra-red spectrum.)

The diffuse ultra-violet and visible spectra of the solid $TiCl_4$ diarsine and $TiCl_4$ 2diarsine have been recorded. The charge transfer band of the former occurs at 4650 Å and of the latter at 5100 Å. Both compounds, however, show the same spectrum in polar solvents ($\lambda_{max} \sim 4600$ Å) and in benzene ($\lambda_{max} = 4480$ Å). This suggests that $TiCl_4$ 2diarsine dissolves by dissociation into $TiCl_4$ diarsine and free diarsine. Both compounds can be recrystallized from benzene and nitrobenzene solutions, but the *cis*-diarsine complex is less soluble, presumably because of the mass action effect of the liberated diarsine.

From the infra-red spectrum and an X-ray diffraction investigation of $TiCl_4$ 2diarsine, we have shown that in the solid state both diarsine molecules are co-ordinated to the titanium atom. The intense infra-red bands at 884, 846 and 741 cm^{-1} of the free diarsine are not present in the compound, but corresponding bands some 20 cm^{-1} higher in frequency are present. This shift is characteristic of co-ordinated diarsine.

The structure of the solid $TiCl_4$ 2diarsine has been studied by single-crystal X-ray diffraction methods. The point symmetry of the titanium atoms is $\bar{4}2m$, with all the atoms in the molecule except the methyl groups lying on mirror planes. The co-ordination polyhedron around the titanium atom is a dodecahedron with eight vertices consisting of four equivalent arsenic atoms and four equivalent chlorine atoms. The arsenic atoms are 2.71 ± 0.02 Å from the titanium atom and are at an angle of 36° to the tetragonal axis. The chlorine atoms are 2.46 ± 0.02 Å from the titanium atom and are at an angle of 73° to the tetragonal axis. So far as we know, these are the first examples of eight-co-ordination of atoms in the first long period of the Periodic Table.

The molecular symmetry of these compounds is the same as that reported for the complex ion $[Mo(CN)_8]^{4-}$ (ref. 4). For this symmetry a set of hybrid bond orbitals determined by Racah[5] from d^4sp^3 orbitals has one group of four with maximum strength 2.968 at an angle of 72° 47′ to the tetragonal axis and another group of four with maximum strength 2.995 at an angle of 34° 33′ to the tetragonal axis.

The direction of the titanium–chlorine bond coincides with that of the first group of these hybrid bond orbitals. The angle between the direction of the titanium–arsenic bond and the tetragonal axis (36°), however, is 2° larger than that of the corresponding maximum strength hybrid orbital, while the neighbouring carbon′–carbon–arsenic angle (117°) is 3° smaller than the ideal trigonal angle of 120°. While barely significant, this suggests that the stability of the molecule is sensitive to the titanium–arsenic distance, and that the angular distortion necessary to obtain this distance is correspondingly distributed between these two angles.

An investigation of the reactions of diarsine with other tetrachlorides and with other halides is in progress. Further details of this work will be published elsewhere in full.

We are indebted to British Titan Products, Ltd. (R. J. H. C.), and to the United States Department of the Army through its European Research Office (G. B. R.) for financial support, and to O. S. Mills and J. S. Rollett for the use of their computer programmes.

UNSTABLE FLOW OF MOLTEN POLYMERS

By J. J. BENBOW, R. V. CHARLEY and P. LAMB

Plastics Division, Imperial Chemical Industries, Ltd., Welwyn Garden City

When molten polymers are extruded at low stresses through dies of circular cross-section, the extrudates are smooth and cylindrical. At higher stresses the surface may be marred by two defects. The first is known as mattness or in its more severe form as 'shark-skin', which consists of ridges at a separation usually small compared with the diameter of the extrudate. It tends to occur at a constant value of the average velocity and is attributed to a stick-slip motion at the die exit[1]. The second is on a larger scale, and the extrudates may take a helical or an irregular, distorted form. This second defect, with which this article is concerned, has been attributed[2] to 'melt fracture' within the polymer. The term fracture implies that the ultimate cause of the distorted extrudates lies in the failure of inter- or intra-molecular bonds within the melt. The evidence to be presented suggests the origin of the defect as being a stick-slip phenomenon at the die wall.

In extrudates of polytetrafluoroethylene and polyvinyl chloride there is clear evidence of macroscopic fracture, with the formation of free surfaces, but it has not been demonstrated that these arise before the material enters the die, they could be produced at the exit In less viscous polymers such as 'Diakon', polythene and polypropylene, fracture is not obvious in the extrudate, but is sometimes inferred from the 'breakage' during extrusion of a central coloured filament embedded in colourless material, in experiments with transparent apparatus the apparent breakage is seen to occur before the material enters the die

As part of an investigation into the causes of distortion in extrudates, we have carried out experiments to examine the possibility of slipping at the die wall Clegg[3] considered the possibility of a stick-slip mechanism being responsible for unstable flow, but his experiments showed that changes in the roughness of the die surface had little effect on the flow of polythene However, it seems likely that the polymer properties rather than the roughness of the surface are usually predominant in determining the onset of slippage, since on a molecular scale all surfaces are rough. In our experiments we measured the distribution of velocity in the die at extrusion-rates above and below the point of instability The movement of a coloured disk of poly(dimethyl siloxane) gum was determined from ciné films of its motion in the die after the sudden application of the appropriate shear rate. Poly(dimethyl siloxane) gums were used because their flow behaviour at room temperature resembles that of molten polymers at much higher temperatures[1] Working at room temperature avoids elaborate temperature control equipment and makes possible the use of easily fabricated transparent 'Perspex' dies

The results are shown in Fig 1, where the relative displacements are shown at equal time-intervals after an arbitrary zero chosen when the velocity of the extrudate reached a constant value It is evident that slipping is indicated in the two high stress measurements (*a*), (*b*), where at low stresses the profile (*c*) is very similar to that predicted (*d*) from the measured shear stress–shear rate relation

The displacement profiles in (*a*) and (*b*) suggest that 'plug' flow is occurring, but similar experiments, using a less viscous silicone gum, show that when slipping takes place there is still, as would be expected for such material, a wide distribution of velocities within the melt This probably explains why it is difficult to detect slipping in low-viscosity polymers since the large range of velocities in the melt mask the relatively small difference in velocity between the die wall and the material in contact with it Conversely, it is easier to detect slippage in highly viscous liquids

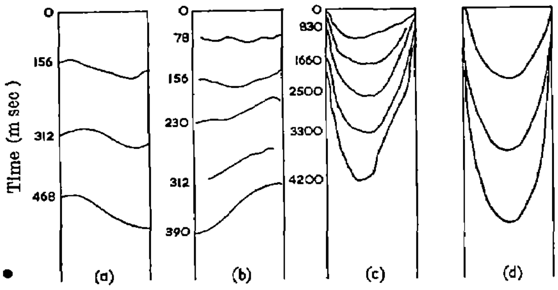

Fig 1 Displacement profiles of poly(dimethyl siloxane) at high and low stresses *a*, stress = 1 2 × 10^6 dynes/cm ^{2}, *b*, stress = 1 2 × 10^6 dynes/cm ^{2}, *c*, stress = 6 × 10^5 dynes/cm ^{2}, *d*, profile calculated from measured stress–shear-rate relationship

Because the stress was applied suddenly and the measurements necessarily ended when the disk was extruded, it may be argued that the experiments are too transient in character and do not correspond to steady-state extrusion However, this criticism applies equally to the experiments above and below the point of instability, and the difference in behaviour remains valid To establish this point more convincingly, additional qualitative experiments were carried out in which coloured material was injected at the die wall under steady-state conditions and these again showed no slip at a low stress, but appreciable slip when the flow was unstable. Similar experiments with highly viscous molten polythene extruded through a glass die also showed that slipping was taking place when the stress was above that at which instability began. Our results show that when molten polymers are extruded at sufficiently high stresses the velocity at the die wall is not zero Since the stress at which slipping occurs is near the stress at which the results of unstable flow in the die can be detected in the extrudate, this suggests that the two effects are connected and that the unstable flow may be due to a stick-slip mechanism

The typical forms which non-cylindrical distorted extrudates take in molten polymers can also be qualitatively explained in terms of a stick-slip mechanism, helical extrudates found with many polymers could be caused by a precession of the point of slipping or the point of maximum slip around the circumference of the die, and the defect known as 'kneeing' in polypropylene could be caused by slippage taking place alternately at opposite ends of a diameter

There is much indirect evidence which supports the stick-slip hypothesis Experiments in which a metal plate is pulled across the surface of a pool of low-viscosity (10^4 poises) siloxane fluid show that at high speeds even a weighted slider will slip When polythene is extruded it has been shown[4] that the 'swelling ratio' passes through a maximum at or below the point of instability, the decline from the maximum when instability sets in could be due to the storage of less elastic energy in the extrudate when slipping occurs Since the stress is a maximum at the die wall and the onset of instability occurs at a critical stress, it is reasonable to expect the cause of the instability to be at the wall rather than in the polymer The effects of slipping are more easily observed with highly viscous polymers, so that any differences in the amount of slip which takes place when using dies of different composition will also be more easily detected with highly viscous polymers Experiments with a very viscous polythene melt suggest that, at high stresses, the stress for a given output-rate is slightly less through a polytetrafluoroethylene than through a steel die of the same dimensions

The facts presented here seem to us strong evidence that unstable flow of molten polymers is associated with slipping at the die wall, and we further suggest that instability may be the result of a stick-slip mechanism

ACCURATE knowledge of chromosome number, morphology and behaviour in mitosis and meiosis has often assisted genetical and evolutionary analysis at the species-level

Recent technical advances have made possible a more accurate study of chromosomes in several species of mammals, including man[1]. By using *in vitro* cultures of biopsy specimens of skin[2,3] and peripheral blood[4], precise delineation of somatic chromosomes may be obtained This involves little discomfort and no danger to the animals As a direct result of these developments, the chromosome number of some twenty-five species and sub-species of primates has been recently determined[5] The anthropoid apes, however, have thus far been relatively neglected, mainly because of the difficulties of obtaining suitable material [See also p 285 of this issue]

The diploid chromosome number of the chimpanzee was determined as 48 by Yeager *et al* [6], who used testis material. This was recently confirmed by Young *et al* [7] in preparations from the bone-marrow of nine animals, but a detailed analysis of the karyotype is not as yet available

We describe here the chromosomes of the gorilla and attempt a comparison with the human chromosome complement, of which several analyses have been published[8]

Two gorillas, one of each sex, kept at the Basle Zoological Gardens, were made available for examination while some of us were on the teaching staff of the World Health Organization international laboratory course in methods of human cell culture and cytology at the Anatomical Institute of the University of Basle Both gorillas are of the Lowland sub-species (*Gorilla gorilla gorilla*, Savage and Wyeman) The male, which was about nine months old at the time of biopsy, was captured in the Cameroons in March 1960 The female was born in the Basle Zoological Gardens on the night of September 22–23, 1959 8 ml of blood were drawn from an arm vein of the male and cultures were prepared by a technique similar to that described for human leucocytes[4]

A skin biopsy was taken from the female and cultured by a plasma clot technique in the presence of a fluid medium Cells from both animals were pretreated with 'Colcemid' (Ciba, desacetylmethylcolchicine) and hypotonic solution, fixed and afterwards stained with acetic orcein or unna blue. Chromosome counts were performed directly on preparations from both primary and (with the skin) transferred cultures Karyotype delineations and measurements of the relative lengths of individual chromosomes were obtained from enlarged photomicrographs Absolute measurements were made with a micrometric ocular

Sexual dimorphism of interphase nuclei Smears of oral mucosa cells were obtained from both animals and stained with thionin[9] 42 per cent of the nuclei in the female possessed a characteristic chromatin mass lying adjacent to the nuclear membrane (Fig 1

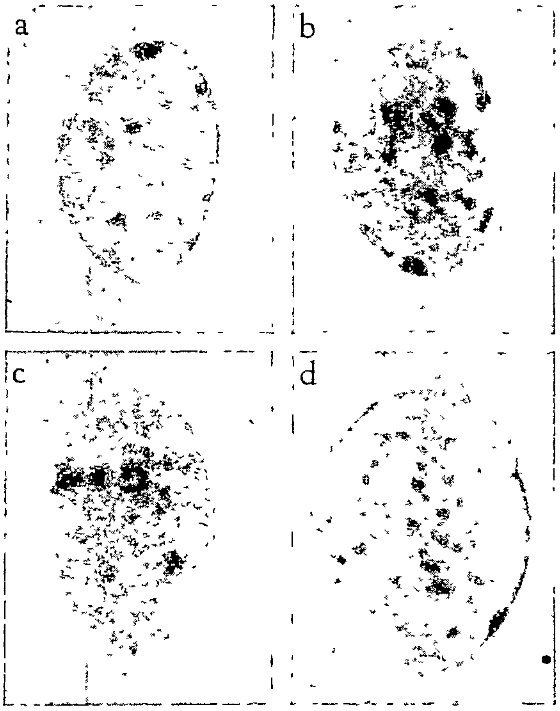

Fig 1 Nuclei of buccal mucosa of the female gorilla (*a*, *b*, *c*) and of the human female (*d*) for comparison

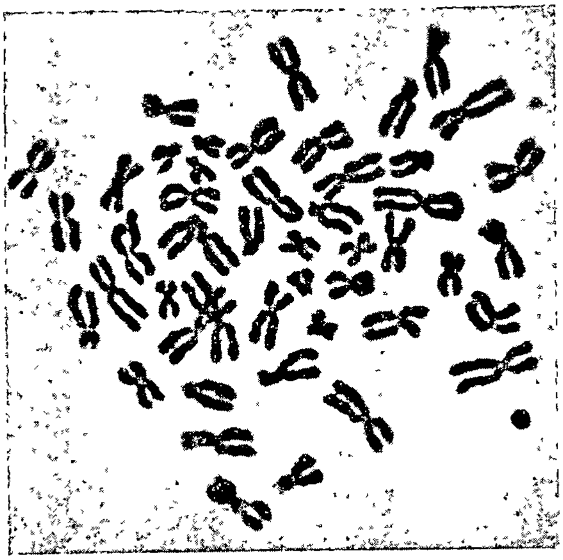

Fig 2 Mitotic metaphase in cultured cell from peripheral blood of the male gorilla Acetic orcein Phase contrast Photographic enlargement × 1,600

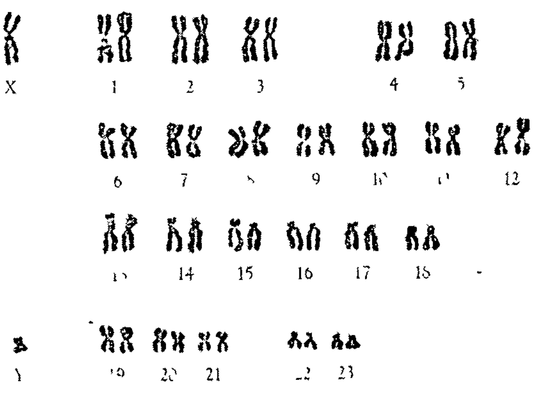

Fig 3 Karyotype of the male gorilla Constructed with the chromosomes of Fig 2

a, b, c) This usually appears larger and more rectangular in shape than in man (Fig 1 d) 4 per cent of the nuclei in the male contained a similar peripheral chromatin mass A variable number of smaller, centrally placed chromocentres were frequently observed in the nuclei of both sexes These are seen less frequently in man The fine, particulate, nucleolar-associated chromatin was observed in about the same amount as usually seen in human nuclei[10] The majority of interphase nuclei of cultured cells derived from the skin of the female also showed a characteristic sex-chromatin body

Chromosome counts The distribution of chromosome counts independently obtained by four of us is set out in Table 1

Table 1 CHROMOSOME COUNTS IN THE GORILLA

Individual	Type of culture	Observer	Chromosome No 45	46	47	48	>48	Total
Male	Blood	J L H	2		2	28	2*	34
Female	Skin	L DC F N	1	2	3	22	—	28
		M F	1	3	1	46	2*	53
	Total		4	5	6	96	4*	115

* Polyploid cells

Table 2 SOMATIC CHROMOSOMES OF THE GORILLA

Group 1–3	Long chromosomes with approximately median centromeres It is difficult to distinguish them from each other The *X*-chromosome is similar to these but easily separated by its length It is the longest chromosome of the complement
Group 4–12	Medium-sized chromosomes with median or sub-median centromeres There is little difference in length between individual pairs in this group, and the chromosomes are difficult, if not impossible, to distinguish one from another by comparative measurements Chromosome 12 can be identified by the presence of a prominent secondary constriction in its long arm, close to the centromere
Group 13–18	Medium-sized acrocentric chromosomes Chromosomes 13, 14, 15 bear satellites, chromosome 16 apparently does not Chromosomes 17 and 18 are shorter than the other chromosomes in this group Their short arms bear prominent satellites
Group 19–21	Medium to short chromosomes with median centromeres These can usually be distinguished from each other and from chromosomes of other groups by their length and centromere position
Group 22–23	Short acrocentric chromosomes Chromosome 22 bears prominent satellites, chromosome 23 has slightly smaller ones The *Y*-chromosome is similar to these chromosomes, but generally appears more metacentric

The diploid chromosome number is 48 The counts of less than 48 chromosomes are probably due to loss of chromosomes during the technical procedures A few of these cells were analysed and no consistent pattern of chromosome loss was found The four cells with chromosome counts greater than 48 were probably polyploid, and two of them had exact counts of 96 chromosomes

Karyotype analysis A summary of the chromosome morphology of the gorilla is given in Table 2,

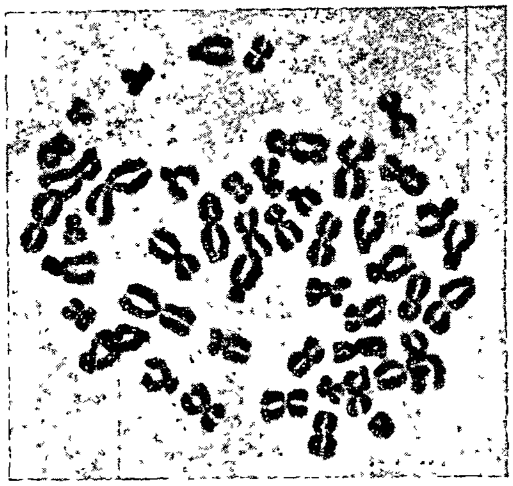

Fig 4 Mitotic metaphase in cultured skin cell of the female gorilla Acetic orcein Phase contrast Photographic enlargement × 1,600

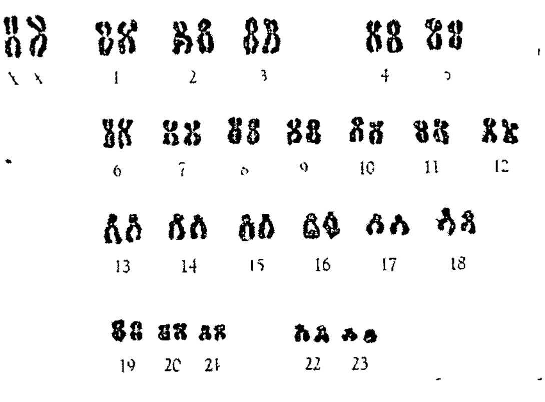

Fig 5 Karyotype of the female gorilla Constructed with the chromosomes of Fig 4

Table 3 MEANS AND RANGE OF VARIATION (IN BRACKETS) OF THE ABSOLUTE LENGTH (IN μ) OF THE LONGEST AND SHORTEST CHROMOSOMES OF THE GORILLA AND HUMAN COMPLEMENT

The estimates are based on measurements performed on 10 cells (treated with colchicine) for each type of tissue

Chromosome measured	Blood		Skin	
	Gorilla	Man	Gorilla	Man
Longest	5.3 (3.6–6.3)	5.6 (4.5–8.0)	6.3 (4.5–8.1)	6.4 (5.9–7.2)
Shortest	1.6 (1.0–1.9)	1.6 (0.9–1.8)	2.2 (1.4–2.7)	1.6 (1.4–1.8)

and representative metaphase plates and karyotypes in Figs 2–5. The complement has been divided into five groups and the chromosomes numbered so far as possible in order of descending length The presence of secondary constrictions or, in the case of acrocentric chromosomes, of satellites, has aided the identification of certain chromosomes This system is based on the same criteria as the Denver standard system of nomenclature proposed for the human chromosome complement

Idiograms of the chromosome sets of the gorilla and man, based on average relative measurements of the chromosomes of seven cells from the two gorillas and on the measurements of human chromosomes given in the Denver statement[11], are compared in Fig 6 The major points of difference are

(1) The X-chromosome of gorilla is metacentric and is the largest chromosome in the complement

(2) Chromosome 12 has a prominent secondary constriction in its long arm, no counterpart of this chromosome is found in the human karyotype

(3) Six pairs of medium-sized acrocentric chromosomes (group 13–18) are present in gorilla and only five pairs in man (groups 13–15, 17–18)

(4) The acrocentric chromosomes of group 13–18 have more definite short arms and more prominent satellites than the acrocentric chromosomes (groups 13–15, 17–18) in man Satellites of chromosome 13 (gorilla) are particularly prominent

While several of the longest autosomes of gorilla are relatively shorter than those of man, absolute measurements of comparable cells (Table 3) show that there is no significant difference between the absolute lengths of the longest and of the shortest chromosomes in the two species

Discussion The similarities between the karyotypes of man and gorilla provide further evidence of the close evolutionary relationship of the two species Man has one acrocentric chromosome less than gorilla, although the number of metacentric chromosomes is the same (Fig 6)

Differences in chromosome number may originate in three ways by polyploidy, polysomy or structural change Polyploidy is a source of karyotype evolution in plants[12], but whether it has played any part in the evolution of mammals remains uncertain[13,14] Polysomy is now known to be a component of pathological chromosome variation in man[15] and the mouse[16] Changes of the type first recorded by Robertson[17] in the Acrididae have been found in two species of mammals, and cause inter- and intra-specific variation in chromosome number with little or no loss of chromosome material[18]

One of the metacentric chromosomes of the gorilla (No 12 in our system) has a prominent secondary constriction in its long arm A similar characteristic autosome has been reported in the chromosome complements of all species of primates which have been examined[5], but not in man The size and position of the secondary constriction are morphologically similar throughout the group, although the autosome which contains it may differ in length and arm ratio from species to species

The significance of this chromosome region is uncertain and its absence in man may be explained in several ways A single reciprocal translocation with one break near the centromere of one of the long acrocentric chromosomes, followed by loss of the centric fragment, is one way in which the change in number may have occurred If the other break were to have been in or near the secondary constriction of chromosome 12, it would also conceivably explain the apparent disappearance of this region

The X-chromosome of the gorilla is relatively longer than the human X-chromosome This might be correlated with the apparent larger size of the sex-chromatin mass in the nuclei of the female gorilla The increased number of centrally placed chromocentres observed in the nuclei of the buccal mucosa cells of the gorilla may be similarly related to the increased number of negatively heteropyknotic regions observed in the metaphase chromosomes Further speculation about the mechanism of karyotype evolution in man and

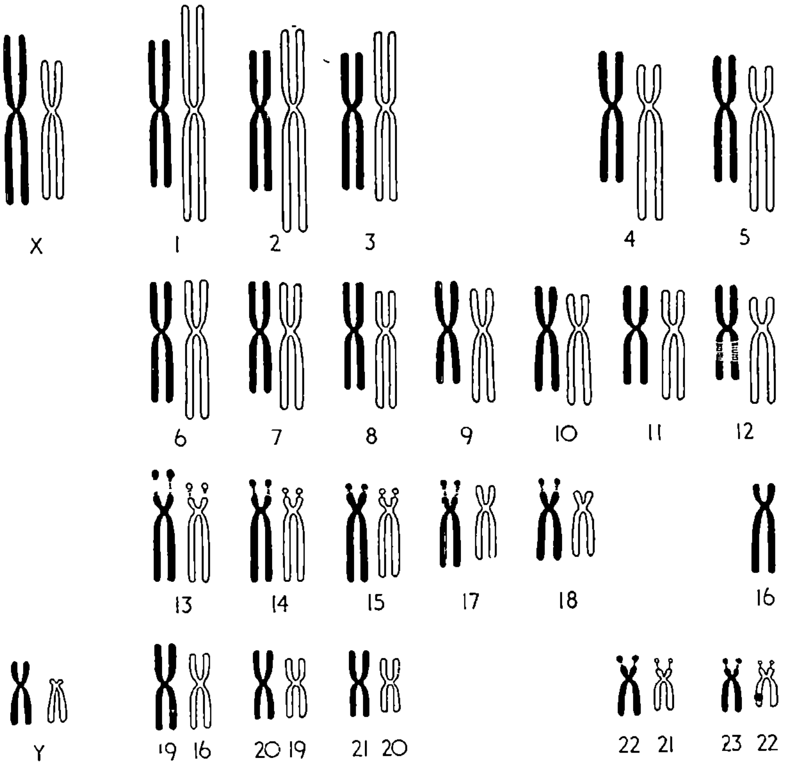

Fig 6 Tentative comparison of the idiograms of gorilla (black) and man (outlined) The human chromosomes are numbered according to the Denver system (ref 11)

the anthropoid apes must wait additional data Now that simple biopsy techniques are available, institutions with collections of anthropoids will perhaps allow examination of the chromosomes of their charges To quote the words of Darlington[14] "Great institutions have been devoted to collecting, and preserving, describing and naming, the bony fragments of our ancestors and relatives, and great bodies of literature have been brought forth by their labours Rightly so Yet at the cost of a few hundred cells, and a few drops of blood, a few moments of discomfort to the animals, and a few hours of work to a cytologist, the genetic record of human evolution could be laid bare It would, perhaps, be worth while"

We wish to thank Drs R Schenkel and E Undritz for their help in collecting the material, and Mr G Clarke for his work with some of the tissue cultures We are indebted to Dr C E Ford for constructive criticism of the manuscript

EFFECT OF GAMMA-RAYS ON THYMUS NUCLEOPROTEIN IN SOLUTION

By Dr A. R. PEACOCKE and Dr B N. PRESTON

Department of Biochemistry, South Parks Road, Oxford

THERE have been many investigations into the action of ionizing radiations on deoxyribonucleic acid (DNA) and, from the point of view of macromolecular structure, the effects may be broadly classified as degradation into smaller fragments and denaturation, that is, loss of the double helical conformation Since these substances occur *in vivo* only in combination with protein, earlier work[1–3] has been extended to an examination of the effects of γ-irradiation on the molecular weight and shape of the soluble deoxyribonucleohistone which may be obtained from calf thymus glands by extraction with water after a preliminary washing of the glands with versene and saline[4] The method afforded dilute solutions of the nucleoprotein in 0 7 m*M* phosphate buffer (*p*H 6 8) The viscosities of these solutions, as measured in Ubbelohde viscometers, changed by less than 5 per cent during five days at 25° C

The molecular weights of nucleoprotein were determined by the method of light-scattering (details in ref 2) and had an average value of 22 × 10^6, with a maximum variation of 10 per cent from one independent extraction to another Better reproducibility was frequently obtained, as in the particular preparations used in this work (Table 1) The stability and reproducibility of this material are thus confirmed Analysis of these preparations (Mr P M Bayley) showed that the N/P ratio was 3 70 in agreement with Doty and Zubay[4] Nucleoprotein solutions were clarified from dust by centrifugation at 29,000 r p m for 30 min (Spinco Model *L*), no fractionation occurred during this centrifugation

The solutions of nucleoprotein (about 0 02–0 09 per cent) in 0 7 m*M* phosphate buffer were irradiated by γ-rays from a cobalt-60 source, without exclusion of oxygen. Dosages (*R*) are stated as eV /phosphorus atom, where 1 eV /phosphorus atom is equivalent to 28 1 or 13 2 kilorads given to a 1 mgm /ml solution of nucleic acid or nucleoprotein, respectively After irradiation, the solutions were stored at 3° C for at least 24 hr and then used for light-scattering work (This precaution proved to be unnecessary since no decrease in viscosity occurred during this period) Aggregation of the nucleoprotein was observed at all dosages greater than 60 eV /phosphorus atom (up to 430 eV /phosphorus atom) Irradiation caused a decrease in viscosity, with no 'after-effect', and no increase in ultra-violet absorption at 259 mμ This suggests that a decrease in molecular size occurred without denaturation of the nucleic acid of the complex

The decrease in weight-average molecular weight (M_L) and in radius of gyration (ρ_g), also derived from the light-scattering measurements, are shown in Fig 1 and Table 1 At dosages of less than 18 eV / phosphorus atom, the relative decrease in molecular weight was a linear function of *R*, in contrast[2] to DNA, where it is dependent on R^2 This relation to *R* appeared to take a new direction above about 15 eV /phosphorus atom in the case of the most extensively studied preparation (*D*, conc = 4 2 × 10^{-4} gm /ml) Moreover, the slope of the relation depended on the concentration of the nucleoprotein during the irradiation, even though *R* is expressed in eV /phosphorus atom, which should allow for the usual variation of an indirect effect with concentration In all these respects, irradiation of the nucleoprotein differed from that of nucleic acid[1–3] Another important difference was that, whereas ρ_g of irradiated nucleic acid was[2] proportional to $M_L^{0\ 5}$, ρ_g of irradiated nucleoprotein declined only very slowly as the molecular weight decreased for example, to 70 per cent of its original value when the molecular weight

had been reduced more than ten-fold, at R = 24 3 and 36 2 eV /phosphorus atom (In terms of a power relationship ρ_g is approximately proportional to $M_L{}^{0\ 2}$) Clearly a process must be occurring whereby the molecular weight can be reduced without a comparable change in the extension of the molecular system primarily contributing to the observed ρ_g The most likely explanation of this is that, on irradiation, the smaller protein units dissociate from the DNA, the molecular weight of which is unchanged and the extension of which is modified only relatively little If this view were correct, the dissociation process should continue until the protein is fully dissociated when M_L should be approximately 4 × 10^6, taking the molecular weight of intact nucleic acid as 8 × 10^6 A value of 4 5 × 10^6 for the mean molecular weight of the fully dissociated nucleoprotein system was observed when the solvent was 2 0 *M* sodium chloride (This process of dissociation by salt has been the subject of separate work[5]) For this dissociated nucleoprotein, for non-irradiated and γ-irradiated deoxyribonucleic acid[2], and, in the present experiments, for γ-irradiated nucleoprotein of M_L < 4 × 10^6 the values of the ratio $M_L^{1/2}/\rho_g$ were all approximately unity, in distinction from the value of 2 3 obtained with the original nucleoprotein This suggests that when the mean molecular weight has fallen to less than 4 × 10^6, the shape is determined by nucleic acid free from protein Beyond this point in the irradiation, the changes previously reported for nucleic acid[1-3] should be observed and denaturation should begin Further experiments are needed to elucidate this point

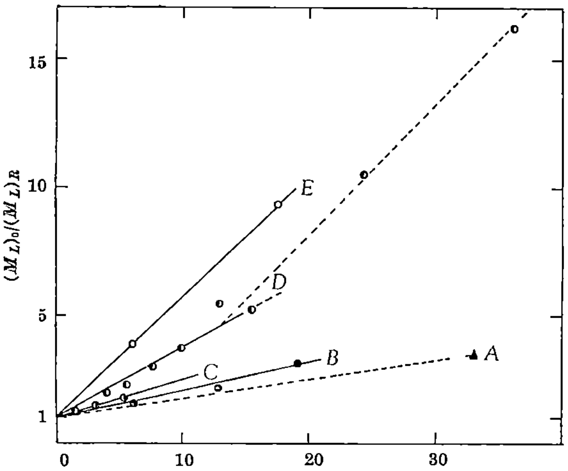

Fig 1 Relative change in the molecular weight of thymus nucleoprotein caused by γ-irradiation

Ordinate = (M_L before irradiation)/(M_L after dosage R) Concentration of nucleoprotein (independent preparations) *A* (▲), 1 15 × 10^{-4} gm /ml , *B* (●), 2 3 × 10^{-4} gm /ml , *C* (◑), 3 77 × 10^{-4} gm /ml , *D* (◐), 4 2 × 10^{-4} gm /ml , *E* (○), 8 77 × 10^{-4} gm /ml

The first major effect of irradiation on the nucleoprotein complex therefore appears to be dissociation of the small protein molecules from the nucleic acid, which remains relatively intact until most of the protein is dissociated This proposal is consistent with the earlier observation of Kaufmann *et al* [6] that the decrease in viscosity of nucleoprotein solutions caused by X-rays did not involve depolymerization of the nucleic acid Hems[7] has obtained evidence for rupture of the linkage between DNA and an acidic protein which is present in nucleoprotein prepared by the method of Kay *et al* [8] At what point in the dissociation nucleic acid itself begins to degrade and denature needs to be determined The changes in M_L and ρ_g show that the nucleic acid must form a central core the extension of which is somewhat modified as the protein is removed, but not in proportion to the decline in its molecular weight This is entirely in accordance with a structure for deoxyribonucleohistone (the protein is almost all histone in this preparation) which consists of a central core of double-helical deoxyribonucleic acid around which the histone chains are wound[9] However, the possible role of any protein bridges must not be overlooked in more detailed work The effect of changes in concentration (Fig 1) indicate that the dissociation process does not have the usual characteristics of an indirect effect Whether or not the protein is degraded before it dissociates is not known

Although nucleic acid by itself is very sensitive to denaturation by γ-rays (1 6 eV /phosphorus atom causes 70 per cent denaturation[3]), there was no evidence for denaturation of the nucleic acid in the irradiated nucleoprotein even up to 40 eV /phosphorus atom This agrees with the chemical evidence of Emmerson *et al* [10] that up to dosages of 1 3 × 10^5 rads ($\simeq$ 50 eV /phosphorus atom with their 0 02 per cent solutions) practically no radicals actually penetrate to the nucleic acid and attack either the bases or the phospho-ester bonds It is also consistent with investigations on electron spin resonance made by Kirby-Smith[11], these detect radical attack and suggest that ionizing radiation should at first damage the protein of a nucleoprotein complex Thus it seems unlikely that γ-irradiation would readily cause denaturation of the nucleic acid in the nucleoprotein, for this is now known to be effected by the free radicals[12]

We thank the Medical Research Council for financial assistance and Dr F Ellis and Mr R Oliver for their co-operation in the use of the cobalt-60 source of the Radiotherapy Department, Churchill Hospital, Oxford

TRANSMISSION OF MOUSE LEUKÆMIA WITH PURIFIED NUCLEIC ACID PREPARATIONS

By Dr ESTHER F HAYS*

Laboratory of Nuclear Medicine and Radiation Biology, School of Medicine, University of California

LEUKÆMIA in the mouse has been demonstrated to be transmitted by hereditary factors There exist certain inbred strains where the spontaneous incidence of this disease is high Because of known genetic transmission of leukæmia I have attempted to transmit the disease with purified nucleic acid preparations from both normal and leukæmic tissues of mice of one of these inbred strains with a high spontaneous incidence of the disease

Gross[1], in 1951, demonstrated that leukæmia of *AKR* mice could be transmitted to $C3H_f/Bi$ mice if they were inoculated with cell-free filtrates of *AKR* leukæmic tissues when new-born Law[2] was able to increase the incidence of spontaneous leukæmia in $(C3H_f \times AKR)F_1$ hybrid mice from 27 7 per cent in control animals to 60 9 per cent in experimental animals by implanting in them fragments of normal thymic tissue from young *AKR* mice Stewart[3] increased the incidence of leukæmia from 23 per cent to 60 per cent in this same hybrid cross by inoculating cell-free filtrates of *AKR* leukæmic tissues into new-born animals Because of the work of these investigators indicating strain susceptibility of the $(C3H_f \times AKR)F_1$ hybrid and $C3H_f/Bi$ mice to transmission of *AKR* leukæmia, new-born hybrid mice and $C3H_f/Bi$ mice were utilized as recipient animals for nucleic acids prepared from tissues of normal and leukæmic *AKR* mice

Preliminary experiments[4] carried out in this Laboratory showed that when nucleic acids were injected subcutaneously into suckling mice less than 24 hr of age of an F_1 hybrid of a $C3H_f \times AKR$ cross, there was an increased incidence of leukæmia in the injected animals when compared with the controls Nucleic acids injected into new-born $C3H_f/Bi$ mice did not result in leukæmia

In the work to be reported here it has been possible to demonstrate, with larger numbers of animals than previously reported, that there is a significant increase in the incidence of leukæmia in $(C3H_f \times AKR)$ F_1 hybrid mice when injected with purified nucleic acid preparations from lymphoid tissues of *AKR* mice These nucleic acids have not been associated with leukæmia development in $C3H_f/Bi$ mice, but other tumours have been seen to develop in one small group of these mice injected with nucleic acid preparations into the thymus

The *AKR/JAX* mice used as a source of spontaneous leukæmia were from an inbred colony that has been maintained in this Laboratory for four years The original litter came from the Jackson Memorial Laboratory, Bar Harbor, Maine

The $C3H_f/Bi$ mice have been maintained as an inbred strain for five years, the original litter being a gift from Dr L Gross, Veterans Administration Hospital, Bronx, New York.

The F_1 hybrid mice were a cross between *AKR* males and *C3H* females of these two strains

The animals were housed in wire-mesh cages containing stainless-steel-sponge basins with wood shavings for nests They were supplied with Rockland rat diet and water *ad libitum* and the pregnant females were given lettuce and oatmeal once weekly The new-born mice used for inoculation were 12–14 hr of age in the subcutaneously injected group and 24–72 hr of age in the intravenously injected group The subcutaneous injections were made on the back with a 30-gauge needle and sealed with collodion in most cases The intravenous injections were made with a 33-gauge needle into the orbital vein The animals were observed until natural death Autopsies were performed in all cases and appropriate organs taken for microscopic investigation when indicated

The nucleic acids were prepared by the method of Simmons as previously described[4], preparations used for intravenous injection substituted xylene sulphonate for sodium dodecyl sulphate as a detergent The final nucleic acid yield from 5 gm of tissue was dissolved in physiological saline and stored as a 1 per cent solution in 1 ml aliquots at −10° until used The preparations contained both deoxyribonucleic acid and ribonucleic acid No attempt was made to separate the nucleic acids in these experiments These preparations will be referred to as DNA–RNA

---

* Present address Department of Biophysics and Nuclear Medicine, University of California School of Medicine, 900 Veteran Avenue, Los Angeles 24, California

The leukæmias in both experimental and control animals were grossly and microscopically similar to the disease which was seen to occur spontaneously in the *AKR* mice The morphology of the tumour was similar to that described by Dunn[5] as a lymphocytic neoplasm or lymphocytic leukæmia

Experiments with $(C3H_f \times AKR)F_1$ *Hybrid Mice* The first group of animals was injected subcutaneously with DNA–RNA $(C3H_f \times AKR)F_1$ hybrid mice of 12–48 hr of age were used The results are summarized in Table 1 Forty-five animals were injected with 0 1 ml of DNA–RNA Seventeen (37 7 per cent) of these animals developed leukæmia Nineteen had received nucleic acids prepared from pooled spleen and lymph nodes of non-leukæmic *AKR* mice with eight developing leukæmia Twenty-six animals had received DNA–RNA from leukæmic *AKR* tissues (spleen, thymus and lymph node) Nine of these developed leukæmia 175 animals were from non-injected litters of the same hybrid cross These animals were raised concomitantly with the experimental animals and under the same conditions Thirty-five animals in this group developed leukæmia, an incidence of 20 per cent The mean age of development of leukæmia was approximately 12 months in both groups The onset of the disease was 6–22 months in the injected group and 8–20 months in the controls These results give a *P* value of less than 0 01 and confirm the results obtained in the preliminary experiments reported elsewhere[4]

Table 1 RESULTS OF INJECTION OF PURIFIED NUCLEIC ACID PREPARATIONS FROM *AKR* MICE INTO $(C3H_f \times AKR)F_1$ HYBRID MICE AT 12–72 HR OF AGE

Amount and route of injection	No of animals	No of leukæmias observed	Percentage
0 1 ml DNA–RNA subcutaneously	45	17	37 7
No injection	175	35	20 0
0 05 ml DNA–RNA intravenously	54	20	37 0
No injection	108	25	23 0

A second group of $(C3H_f \times AKR)F_1$ hybrid animals was injected intravenously with 0 05 ml of DNA–RNA from leukæmic *AKR* tissues The injections were made in the orbital vein at 24–72 hr of age The controls again were alternate non-injected litters The results of these experiments are included in Table 1 Fifty-four animals were injected with 0 05 ml of DNA–RNA intravenously Twenty of these animals (37 per cent) developed leukæmia at an average age of 10 5 months 108 control mice were observed and 25 mice (23 per cent) developed leukæmia at an average age of 10 7 months The *P* value for these results was less than 0 05

Tumour cells from ten of the leukæmias developing in mice injected with DNA–RNA were implanted intraperitoneally into 2-month-old $C3H_f/Bi$, *AKR*, and hybrid mice None of 20 *C3H* mice developed leukæmia Four of 19 hybrid mice and four of 23 *AKR* mice developed leukæmia In one case leukæmias occurred in *AKR* and hybrid mice receiving the same cell suspension The leukæmias developed within 4 wk of injection of cells and were assumed to be due to progressive growth of injected cells and not to have developed spontaneously

Tumour transfers were carried out from cells of three leukæmias developing in control hybrid mice No leukæmias developed in the 5 injected $C3H_f/Bi$ and 4 hybrid mice, but 2 out of 4 injected *AKR* mice developed the disease within 4 wk of transfer of cells This would indicate that the leukæmias developing in the control and DNA–RNA injected mice had essentially the same transfer characteristics However, the lack of consistent growth of these tumours in hybrid mice is difficult to explain

Experiments with $C3H_f/Bi$ *Mice* A group of similar experiments was carried out utilizing the $C3H_f/Bi$ mice Ninety mice were injected intravenously with DNA–RNA at 12–72 hr of age Two leukæmias developed at 11 months

Three litters were injected with 0 05 ml of a DNA–RNA preparation to which had been added an equal volume of 50 per cent sucrose These animals were injected into the thymus at 2–5 days of age The majority of the animals died during the first 24 hr after injection However, five animals in this group survived Three of these animals developed parotid gland carcinomas and one developed an adrenal gland neoplasm The parotid tumours occurred at 7, 9 and 10 months of age and were local bilateral growths The adrenal tumour was found at 10 months of age It was metastasized to the liver and thoracic lymph nodes The remaining mouse died of pneumonia at four months of age

Four litters were injected with 0 05 ml of cell-free 'Selas'-filtered extract of *AKR* leukæmic tissues into the thymus at 2–5 days of age Eight of these animals survived Their litter mates died during the first 24 hr after injection The cell-free extract was prepared as that described previously[6] None of the eight animals that had received cell-free extract developed neoplasms or leukæmia

One leukæmia was found in 114 non-injected control $C3H_f/Bi$ mice raised at the same time and under the same conditions as the experimental animals

Other work[4] had shown that the subcutaneous injection of DNA–RNA at 12–24 hr of age in seventeen $C3H_f/Bi$ animals did not result in leukæmia development However, cell-free ('Selas'-filtered) extracts when injected into 36 mice of this strain resulted in the development of ten leukæmias No leukæmias were seen in non-injected control animals

A summary of the results of these experiments with $C3H_f/Bi$ mice is given in Table 2 The tumours that developed in the DNA–RNA injected mice are grossly and histologically similar to those described by Stewart[7] as occurring in $(C3H_f \times AKR)F_1$ hybrid mice after injection with cell-free extracts and later shown by Stewart and Eddy to be due to the polyoma virus[8] Neoplasms of the parotid and adrenal gland have not been noted to occur spontaneously in the $C3H_f/Bi$, *AKR* or hybrid colonies

These experiments demonstrate that the injection of nucleic acid preparations from normal and leukæmic *AKR* mice into new-born $(C3H_f \times AKR)F_1$ hybrid mice is associated with a statistically significant increase in the incidence of leukæmia in the injected mice when compared with non-injected controls

Table 2 RESULTS OF INJECTION OF PURIFIED NUCLEIC ACID PREPARATIONS COMPARED WITH THOSE OF CELL-FREE EXTRACTS AND NON-INJECTED CONTROLS IN $C3H_f/Bi$ MICE

Material	Age injected	Route of injection	No of animals	No of leukæmias	Other tumours
Cell-free extract	12–24 hr	Subcutaneous*	36	10	0
Cell-free extract	2–5 days	In thymus	8	0	0
DNA–RNA	12–24 hr	Subcutaneous*	17	0	0
DNA–RNA	12–72 hr	Intravenous	90	2	0
DNA–RNA	2–5 days	In thymus	5	0	4†
No injection			114	1	0

*These results are taken from previously published experiments (ref 4)

†3 Parotid tumours, 1 adrenal tumour

However, nucleic acids from leukæmic *AKR* mice prepared and injected in the same manner do not increase the incidence of leukæmia in $C3H_f/Bi$ mice

These two observations would seem to indicate that an inherited tendency to develop leukæmia in the hybrid mouse can be accentuated by the addition of nucleic acids from lymphoid tissues of a high-incidence leukæmia strain in the new-born period This is possibly an observation of the effects of addition of more *AKR* genetic material with leukæmogenic properties to that of a mouse with an inherited leukæmic tendency from its *AKR* parent

The $C3H_f/Bi$ mouse is not susceptible to leukæmia induction with nucleic acids but is susceptible to induction of the disease with cell-free extracts of *AKR* tissues, presumably containing a virus[1] This would suggest that viral nucleic acid is not involved in the observations made in the hybrid strain and that the situation is more analogous to that observed in bacterial transformation where the DNA of the donor combines with that of the recipient, resulting in the appearance of donor characteristics in the recipient bacterium That is, the hybrid mice, after having received *AKR* nucleic acid, are more like their *AKR* parent, so far as tendency to develop leukæmia is concerned, than non-injected F_1 hybrids

The observation of the induction of parotid and adrenal tumours in $C3H_f/Bi$ mice injected into the thymus with nucleic acid from *AKR* leukæmic tissues would indicate that this nucleic acid preparation very likely contained DNA from polyoma virus This preparation was made from a different *AKR* leukæmic mouse than that utilized for the subcutaneous and intravenous injections An agent that induced parotid gland and other neoplasms in $C3H_f/Bi$ mice was found initially in cell-free extracts of tissues of the leukæmic *AKR* mouse[9] Latarjet[10] has carried out experiments using the detergent method of isolating nucleic acids from *AKR* leukæmic tissues He also found no increased incidence of leukæmia in *C3H* mice injected subcutaneously with these nucleic acid preparations at birth, but 5 per cent of the injected animals after an average latency of 202 days developed multiple tumours which were interpreted by the author as being due to the inclusion of DNA from the polyoma virus in his preparations The experiments of Di Mayorca *et al* [11] and Smith *et al* [12] have shown the polyoma virus to be a DNA virus

Experiments are now in progress to investigate the effects of nucleases on the induction of leukæmia and other tumours with these nucleic acid preparations A group of hybrid mice receiving nucleic acid preparations with litter-mate controls is under investigation

ENHANCED EFFECT OF TOTAL-BODY X-IRRADIATION IN MICE UNDER MILD HYPOTHERMIA

By Dr H. J G BLOOM

Radiotherapy Department, Royal Marsden Hospital, and Institute of Cancer Research,
Royal Cancer Hospital, London, S W 3

AND

K. B. DAWSON

Radiobiology Research Unit, Institute of Cancer Research, Royal Cancer Hospital, London, S W 3

It is well established that the sensitivity of a variety of biological species to damage by ionizing radiation is dependent on the presence or absence of oxygen in the environment at the time of irradiation An increase in tissue oxygen can be brought about through breathing oxygen under raised pressure or by lowering its consumption by means of hypothermia

The use of hypothermia in man to raise the cerebral oxygen concentration and thereby perhaps increase the radiosensitivity of intracranial tumours is being investigated at the Royal Marsden Hospital, London This has been undertaken to try to improve the extremely poor results obtained by conventional methods of treatment in patients suffering from malignant grades III and IV cerebral astrocytomata (glioblastoma multiforme) Under generalized mild hypothermia (30–32°) moderate doses of whole brain X-irradiation (300–450 r given in daily fractions of 50–150 r) appear to produce an exaggerated cerebral reaction[1] Many problems were encountered in this treatment and, while the clinical work was in progress, the present investigation was undertaken to investigate the influence of hypothermia on the response of mice to whole-body irradiation

Eight-week-old albino male mice of Theiler's original strain were anæsthetized with intraperitoneal sodium pentobarbitone (approximately 50 mgm /kgm body-weight) and then suspended by a plastic collar in a thermostatically controlled water-bath, the entire body with the exception of the head being immersed The bath was kept at various temperatures between 29° and 37° (Table 1) and the colonic temperature of each mouse was continuously recorded by a mercury thermometer *in situ* The temperatures of the anæsthetized mice fell to approximately 29° (room temperature, 20°) and remained in this region until they were placed in the water-bath, the colonic temperatures reached that of the bath within 10 min of immersion

The mice were irradiated five at a time in the water-bath and allowed to remain immersed for 20 min before and after the irradiation The X-ray factors were 140 kV , 5 m amp , focal skin distance 38 cm , no added filtration, half-value layer 2 mm aluminium, dose-rate 25 r /min After removal from the bath the mice were placed in a box at 37° to recover and dry out

The effects of total-body irradiation with a dose of 550 r was studied, but the head, not being shielded by the water, received 12 per cent more irradiation For each of the temperatures used, 10 control mice were treated under identical conditions, but shielded in each case from irradiation by a 3-mm thick lead screen

In these experiments the criterion of an irradiation effect was death of the animal within 30 days The majority of fatalities occurred between the tenth and twentieth day following irradiation There did not appear to be any difference in the mode of death at the different temperatures, nor with the number of animals involved could a significant relationship be established between time of death and temperature

The results (Table 1) show an increased mortality among the animals treated under mild hypothermic conditions (31–35°) At a temperature of 29° a protective effect was noted No deaths occurred in any of the control animal groups

Table 1 EFFECT ON MOUSE SURVIVAL OF COMBINED HYPOTHERMIA AND 550 R TOTAL-BODY X-IRRADIATION

Temperature	No. of mice	Survivals	Died (per cent)
29°	19	19	0
31°	19	7	63
33°	18	11	39
35°	18	13	28
37°	21	18	14

Ten control animals for each temperature, shielded from irradiation no deaths

Hypothermia, by lowering the metabolic rate and by increasing the amount of oxygen dissolved in the plasma, may lead to an increase in the oxygen environment of tissues and thereby perhaps an increase in radiosensitivity Working against these tendencies to an increased oxygen tension in hypothermia, however, may be (1) a reduction of blood-flow due to the decreased cardiac output, the increased peripheral resistance and the increased viscosity of the blood, (2) a shift of the oxygen dissociation curve to the left, which will interfere with the liberation of oxygen from hæmoglobin, (3) a fall in the rate and depth of respiration On the other hand, normal well-oxygenated tissues are considered to be practically at their maximum radiosensitivity In such circumstances no appreciable increase in response to ionizing radiation is expected to follow a further rise of oxygen tension, as opposed to relatively anoxic foci in tumours which have outgrown their blood supply[2] The oxygen tension in normal bone marrow, however, appears to be low compared with that of muscle and subcutaneous tissue[3] If this is true, hypothermia may increase the oxygen environment and therefore the radiosensitivity of normal marrow The chief cause of death in mice following 550 r whole-body irradiation is marrow failure Alternatively, the lowered temperature may increase radiosensitivity by interfering with the efficiency of detoxifying and repair mechanisms or the transport of tissue breakdown products A third possibility is that hypothermia, like mild whole-body irradiation, may increase the response to local irradiation[4] through the production of certain plasma factors[5] A recent report[6] suggests that a greater difference in litter size, in viability at birth, in developmental curves and in behaviour changes occur in chicks following whole-body pre-natal irradiation of the mother compared with localized direct irradiation of the gravid uterus

The influence of temperature on the degree and the timing of response to γ- and X-ray irradiation of various biological systems have been investigated by many workers with somewhat conflicting results In general, profound hypothermia (15° C or less) reduces the damage resulting from irradiation, and such observations have recently been reviewed by Weiss[7] Heat, on the other hand, appears to have an additive effect on irradiation[8,9]

Although most investigators report that hypothermia reduces radiosensitivity, an increased effect at reduced temperatures has been reported in the broad bean root[10], in *Tradescantia* microspores[11], in mouse skin[12] and in mouse carcinoma tissue[13] Changes of temperatures at the time of irradiation do not appear to influence the response of isolated mammalian cells *in vitro*[14–16], but may bring about pronounced effects in more complex tissue systems during *in vivo* studies[7,17–20]

The results of the present investigation appear to support a protective effect for hypothermia at 29° against ionizing radiation, but reveal an enhanced effect of irradiation with a lesser degree of hypothermia, the peak being at 31–32° The difference in survival-rate following whole-body irradiation at 31° and 29°, a change of only 2 degrees, is striking The results in mice reported here and the severe cerebral reactions observed in patients treated by whole-brain irradiation[1] suggest that the increased response to irradiation during mild hypothermia is more likely to be due to systemic humoral factors rather than a local oxygen effect (for example, stress endocrine changes, tissue breakdown products)

These experiments, including an investigation into the possible mechanisms involved, will be reported in greater detail elsewhere

We wish to thank Dr P Alexander for his helpful criticism and discussions

SIMPLIFIED TECHNIQUE FOR ISOLATION OF SUB-CELLULAR PARTICLES

By Dr. DAVID W E SMITH*

Clinical Endocrinology Branch, National Institute of Arthritis and Metabolic Diseases,
National Institutes of Health, Bethesda 14, Maryland

THE heterogeneity of particles isolated in the classical sub-cellular fractions[1-3] makes it desirable that tissue homogenates be divided into a greater number of fractions each of which can be tested for enzymic activity and chemical composition Density gradient centrifugation has been widely used for this, but it has certain disadvantages These are difficulty in constructing reproducible gradients, especially of the continuous variety, difficulty in estimating the sizes of the particles collected[4], and difficulty in collecting the particles from the various levels in the gradient after centrifugation Moreover, in order to construct gradients of sufficient density to separate particles, many workers have used extremely hypertonic solutions which have probably had deleterious effects on the morphology and activity of the particles collected

My technique utilizes layering of aliquots of a homogenate in 0 88 *M* sucrose over relatively large amounts of clear 0 92 *M* sucrose solution, and centrifugation of a series of these preparations at successively greater forces Each increased force sediments all the particles sedimented by previous forces, together with some smaller particles not sedimented by the lower forces The value of using 'two phase' preparations has been demonstrated[5] Only particles which sediment completely are collected in the precipitate Smaller particles are decanted with the supernatant, and since all the particles start sedimenting at essentially the same level at the top of the tube, there is negligible contamination of desired particles in the precipitate with smaller particles The clear phase, moreover, washes the particles as they sediment and frees them of contaminants

DeDuve *et al* [6] have shown that the integral force applied to a preparation can be approximated by multiplying the force used by the time during which it was applied The product is expressed in gravity-minute (*g*-min) units I have found it desirable to use the swinging bucket rotor (*SW* 39) in the 'Spinco' model *L* centrifuge because sedimenting particles in angle rotors move first to the centrifugal side of the tube and then slide down the tube to the bottom In the horizontal rotor the distance that a particle must move from the thin layer of homogenate to the bottom of the tube can be measured accurately, and at the end of centrifugation there are fewer particles adhering to the sides of the tube

No special precautions were taken to prevent vibration during acceleration and deceleration of the rotor Such vibration would appear to be less critical in this procedure, with a packed sediment well separated from suspended particles, than in density gradient methods, where zones of suspended particles must be stabilized The acceleration and deceleration times were short relative to centrifugation time at top speed, and only the latter was used in the calculation To test the efficacy of our technique, a survey of uricase and cytochrome *c* oxidase in the particles of rat liver was done Particles were sedimented by layering 0 5 ml of 20 per cent rat liver homogenate in 0 88 *M* sucrose over 3 0 ml of 0 92 *M* sucrose and centrifuging a series of these preparations for varying periods of time at different speeds Aliquots of the supernatants were used for enzymic assays Cytochrome *c* oxidase was assayed by the technique described by Smith[7] Uricase was assayed by the technique of Hogeboom and Schneider[8] with modifications as suggested by Kalckar[9] The results are shown in Fig 1 The activity of the enzyme in each supernatant is plotted against the integral centrifugal force used to prepare it The centrifugal forces shown are those applied at the bottom of the tube The curves thus show the disappearance of these enzymes from the homogenate and indicate the forces required to precipitate the particles containing the enzymes

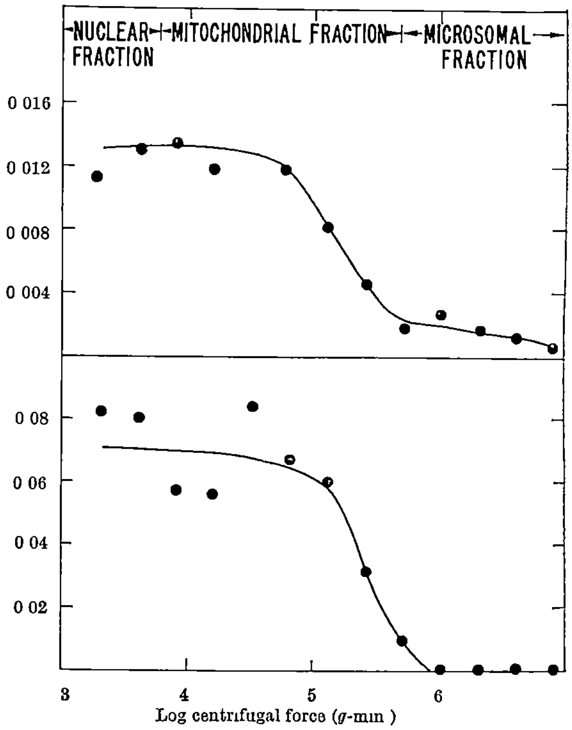

Fig 1 Distribution of uricase and cytochrome *c* oxidase in sub-cellular particles of rat livers

Ordinates, cytochrome *c* oxidase activity (top) is given as the constant for the first order reaction observed colorimetrically in sec $^{-1}$ units, uricase activity (bottom) as micromoles of uric acid destroyed by each fraction in 30 min

Comparison of the forces needed to precipitate these enzymes with those used to prepare classical sub-cellular fractions[10] (indicated at the top of Fig 1) shows that both of the enzymes are 'mitochondrial' The range of forces precipitating particles containing either of these enzymes is much narrower, however, than the range used to prepare the whole mitochondrial fraction From a knowledge of these forces, a fractionation method can be devised by which particles containing either of these enzymes can be isolated in the absence of other particles usually isolated with the 'mitochondrial fraction'

---

*Present address Department of Pathology, Yale University School of Medicine, New Haven, Connecticut

Calculation of the diameters of the particles (assuming that they are spherical) can be made using the following expression, which may be derived from the equations given by DeDuve and Berthet[6]

$$d^2 = \frac{63\ \eta\ (\log_{10} r_2 - \log_{10} r_1)}{(\sigma - \rho)\ (\text{r p m})^2\ T}$$

where d = particle diameter (cm), η = viscosity of the suspending medium (poises), T = time for sedimentation (min), σ = particle density (gm /c c) ρ = density of the suspending medium (gm /c c), r_1 = the distance from the axis of rotation to the surface of the suspension in the tube (cm), r_2 = the distance from the axis of rotation to the bottom of the centrifuge tube (cm), and r p m = the speed of centrifugation (revolutions per minute)

The value for the density of these particles was that determined in sucrose and ordinary water by Beaufay *et al*[11] The approximate average density of 1 22 was used for both cytochrome *c* oxidase and uricase, although the uricase particles appear to be less homogeneous Since this value was determined by isopycnic centrifugation, the density of any particle undergoing osmotic shrinking will be increased relative to that in isotonic solutions or in 0 92 *M* sucrose used in the present experiments Its diameter, calculated from the above equation, will be underestimated Density values obtained in sucrose–deuterium oxide gradients[11] were not used because of the increased density of uricase apparently due to bound deuterium oxide The values for the density and viscosity of 0 92 *M* sucrose were obtained from DeDuve *et al*[12]

The diameters calculated from the data in Fig 1 showed a range of 0 52–1 58μ for cytochrome *c* oxidase-containing particles, and 0 26–0 75μ for those containing uricase These may be compared with the values reported by Beaufay *et al*[11], where calculation was made by reference to 'standard conditions' of 0 25 *M* sucrose and 0° C They found the diameter of cytochrome *c* oxidase-containing particles to be about 0 5–1 2μ and of uricase-containing particles, 0 2–0 7μ Other workers have also found the 'mitochondrial' oxidative enzymes to be associated with larger particles than the 'mitochondrial' (lysosomal) lytic enzymes[10,13]

ALTERATIONS IN CONNECTIVE TISSUE AND INTESTINE PRODUCED BY HYPERVITAMINOSIS A IN *XENOPUS LAEVIS*

By GERALD WEISSMANN

Strangeways Research Laboratory, Cambridge

RECENT experiments have indicated that vitamin A may liberate from intracellular lysosomes a cathepsin-like protease active on such extracellular materials as cartilage matrix[1]. Thus the depletion of cartilage matrix observed in rabbits made acutely hypervitaminotic A resembled that produced by an exogenously administered protease, papain[2] Considerable catheptic activity has been demonstrated in the tails of amphibian larvæ, this is greatest at the time of tail resorption during metamorphosis[3] If the hypothesis of vitamin A action on lysosomes is correct, resorption of the tails of amphibian larvæ might accompany hypervitaminosis A, since the vitamin would cause release of cathepsins from the lysosomes, which Novikoff has shown are abundant in amphibian tails[4].

Larvæ of *Xenopus laevis* were therefore exposed to high doses of vitamin A, and the effect of this treatment on gross and microscopical structure was observed. Although the predicted effects on connective tissue were seen, and will be briefly noted, this article is chiefly concerned with an entirely unexpected effect of this régime on the intestines of the larvæ

Larvæ of *Xenopus laevis*, obtained through the generosity of Dr. R T Sims, Department of Anatomy, University of Cambridge, were grown under conditions suggested by Nieuwkoop and Faber[5], at room temperature and fed with nettle powder thrice weekly Twenty-eight animals were given 2 mgm of synthetic vitamin A alcohol ground with their food twice a week the tank contained 800 ml of tap water for each group of 14 larvæ An equal number served as controls

Treatment was continued for three months, beginning with larval stages 49–50 By the end of the experiments, the treated animals had progressed to stage 59–61, while some of the controls had undergone metamorphosis After three weeks, six of the experimental animals were transferred to fresh water, and given the normal diet without added vitamin A At varying intervals, larvæ were killed with 'Nembutal', fixed *in toto* in acetic alcohol, embedded, and sections were stained with hæmatoxylin and eosin and with toluidine blue

Grossly, the first change noted was a drooping of the tentacles of the larvæ exposed to the vitamin This occurred on the fourteenth or fifteenth day of treatment, and resembled in many ways the drooping of the ears of rabbits made hypervitaminotic A, or of those given papain intravenously[2] After 18-20 days, however, another change became evident The stools of the animals, which had been well-formed, dark, and solid, assumed a mucinous, thready appearance and floated in strands at the surface of the tank This change persisted to the end of the experiment, and simple addition of vitamin A to a suspension of normal stools did not produce a similar

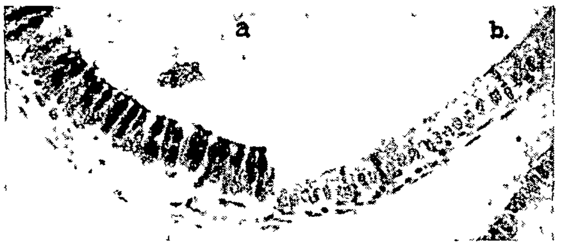

Fig 1 Photomicrographs of fore-gut of *Xenopus laevis* larvæ (stage 53–54) stained with toluidine blue (*a*) is from an animal exposed to high doses of vitamin A alcohol for 42 days There is a marked overgrowth of metachromatically staining goblet cells, and the epithelium is more columnar than in the control (*b*) (× 216)

change That this represented diarrhœa was readily observed by isolating individual normal and hypervitaminotic larvæ and noting the increased number of stools eliminated by the latter By the twenty-first day of the experiment, most of the hypervitaminotic larvæ had developed pronounced kyphoscoliosis and also showed definite resorption of the tail, with a loss of the fine flagellar structure of that appendage, several actually developed fractures of the tails, along with shrivelling and resorption Associated with the gross skeletal deformity was a change in the normal apposition of the upper and lower jaws, the experimental group having developed a prognathic appearance

Histologically, the most remarkable change was in the gut of the hypervitaminotic animals Sections of gut taken before the appearance of mucinous stools were unremarkable, but those taken two or three weeks later showed a great increase in the number of metachromatically staining goblet cells (Fig 1*a*) These, situated mainly in the proximal gut and in the lower colon, were increased not only in absolute number (per high-power field in sections cut at 7µ) but also in ratio to the normal cells of the epithelium These metachromatic cells were secreting discrete strands of metachromatic material into the lumen The fæcal material in the gut of treated animals was diffuse, mucinous, and mixed with metachromatic strands, thus contrasting with similar debris in the lumen of controls where it was compact and entirely orthochromatic

The whole character of the hypervitaminotic gut was altered At comparable larval stages, the intestines of the treated animals had better developed villi, abnormally deep columnar epithelium (Fig 1*a*, *b*) and at stages before metamorphosis (stages 49–60) the gut closely resembled the organ in control animals after metamorphosis, except for the remarkable overgrowth of goblet cells In other structures, especially in the resorbing tail and the collapsed tentacles, there was a decrease of the metachromatically staining material of the ground substance, in these chronically hypervitaminotic animals the metachromasy of cartilage was almost unaffected, unlike that of acutely hypervitaminotic rabbits[2] Those larvæ which were placed in the recovery group lost all the gross morphological stigmata of hypervitaminosis A within 21 days, and their gastro-intestinal tracts were indistinguishable histologically from those of the controls, despite the continuance of mucinous diarrhœa for 8–10 days after transfer to a medium without vitamin A

The above findings are in accord with two recently postulated effects of vitamin A Moretti and Wolf[6] have found that mucopolysaccharide-bound hexosamine is decreased in the colon of hypovitaminotic A rats, and have suggested that vitamin A is necessary for mucopolysaccharide synthesis It has been postulated that vitamin A causes the release of a proteolytic enzyme from cells or their organelles[2–7] which afterwards acts on the protein–polysaccharide complexes of connective tissue In amphibian tails and tentacles the means for their own resorption during metamorphosis must be 'built in' as an active lysosome–cathepsin system, and the observation that these structures are affected by vitamin A, would support the lysosomal theory of vitamin A action[1] If the degradation of mucoprotein complexes in the epithelium of gut or in the ground substance of connective tissue by cell-released proteases were to act as a stimulus for the resynthesis of protein-polysaccharide complexes by competent cells, then the lysosomal action would explain the intestinal as well as the cartilagenous changes

This work was done in the laboratory of Dr S Fitton Jackson during the tenure of a special research fellowship of the National Institute of Arthritis and Metabolic Diseases, United States Public Health Service

SEPARATION OF BACTERIA BY COUNTER-CURRENT DISTRIBUTION

By G DAVID BAIRD, PER-ÅKE ALBERTSSON and BENGT v. HOFSTEN
Institute of Biochemistry, University of Uppsala

THE method of counter-current distribution has been successfully applied to the separation of important biochemical substances[1] Even very large particles, such as proteins of high molecular weight and viruses, may be studied by this method, if aqueous-phase systems containing two different water-soluble polymers are used[2–4] In this case, the use of organic solvents, which may cause denaturation, is avoided

In the present article we report some results of work on the distribution of whole cells, in this case bacteria, in these aqueous polymer phase systems It has been found that the nature of the distribution in a given phase system of this type is frequently different for different bacteria. On the basis of this observation, it has been found possible to separate even quite closely related bacterial types by means of counter-current distribution The

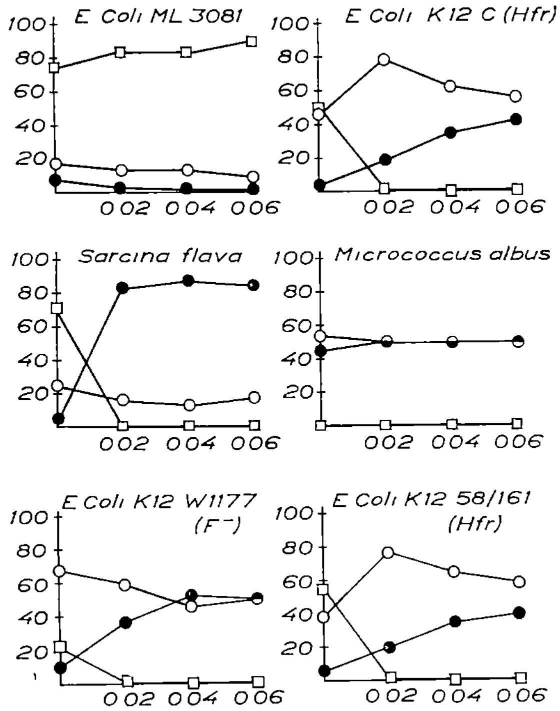

Fig 1 Distribution patterns of different types of bacterium in phase system (D_5^{48}–PEG_4^{6000}) in the absence and presence of sodium chloride Abscissa, concentration of sodium chloride (*M*), ordinate, quantity of cells present in each phase and at the interface (per cent of total added) Experiments carried out at 20° C Bacteria cultured overnight on Penassay broth at 37° C, collected in growing state and afterwards washed twice in 0 01 *M* potassium phosphate buffer, *p*H 6 9, at 5° C In general, the distribution of each bacterial type examined by mixing 1 ml of washed cell suspension of *E*(1 cm, 400 mμ) = 8 0 with 9 gm of aqueous polymer solution to produce about 10 gm of cell/phase system mixture, in which the polymers were at their correct concentration The bottom phase of this mixture had a volume of 4 6 ml and the top phase a volume of 5 2 ml
●, Bottom phase, ○, interface, □, top phase

results obtained may be of interest not only to microbiologists but also to other cell research workers, since in principle it should also be possible to apply the method to the separation of other types of whole cells

Phase systems consisting of aqueous solutions of dextran and polyethylene glycol have been used for examining the distribution of bacteria Systems containing these polymers have previously been employed mainly for studying the distribution of proteins[2,3] The particular phase system that was found most appropriate for the studies on bacteria was that containing 5 per cent w/w dextran ('Dextran 500', limiting viscosity number 48 ml /gm, obtained from A. B Pharmacia, Uppsala, Sweden) and 4 per cent w/w polyethylene glycol ('Carbowax 6000', average molecular weight 6,000–7,500, obtained from Carbide and Carbon Chemicals Co, New York) This phase system will be designated (D_5^{48} – PEG_4^{6000}) in this article The aqueous solution of these polymers was lightly buffered with 0 01 *M* potassium phosphate buffer, *p*H 6 9 The distribution of proteins in the dextran/polyethylene glycol systems was found to be markedly influenced by the presence of electrolytes[2,5] It seemed therefore of interest also to examine the effect of electrolytes on the distribution of bacteria Accordingly, the effect of increasing concentrations of sodium chloride on the distribution of each bacterial type in (D_5^{48} – PEG_4^{6000}) was also studied

The behaviour of a number of different types of bacteria under these conditions is illustrated in Fig 1 In the case of *Escherichia coli ML* 3081, it can be seen that in the absence of sodium chloride the majority of the cells are suspended in the top phase, and that increasing concentrations of salt scarcely affect this distribution pattern at all It appears that other *E coli ML* strains also behave in a similar fashion In the case of the *E coli K* 12 *C* (*Hfr*) strain, too, a large portion of the cells are present in the upper phase in the absence of salt Increase of salt concentration to 0 02 *M*, however, causes these cells to be transferred to the interface and the bottom phase It seems to be a general rule that the distribution of bacterial cells in this phase system is more sensitive to increasing concentrations of sodium chloride in the region 0 00–0 02 *M* than at higher salt concentrations Thus, the distribution of *Sarcina flava* is also altered markedly by increasing the concentration of sodium chloride to 0 02 *M* In the absence of salt, the majority of the cells of this bacterium are present in the top phase, but are transferred to the bottom phase when 0 02 *M* sodium chloride is added Increase of the salt concentration to 0 06 *M* does not appear to affect the distribution any further *Micrococcus albus* is another example of a bacterium the distribution of which is scarcely affected by increase of concentration of sodium chloride from 0 00 to 0 06 *M* In this case, about half the cells are present at the interface and about half in the bottom phase at all the salt concentrations used

It is thus clear that different types of bacteria are distributed in quite different fashions in this phase system However, on occasions different bacteria can also behave in the same manner For example, the *E coli K* 12 strains, 58/161 (*Hfr*) and C 600 (*F*⁻), and also *Bacillus megaterium* are distributed in this system in a very similar way to *E coli K* 12 *C* (*Hfr*) (*F*⁻ indicates standard female mating type, *Hfr* indicates male giving high frequency of recombination)

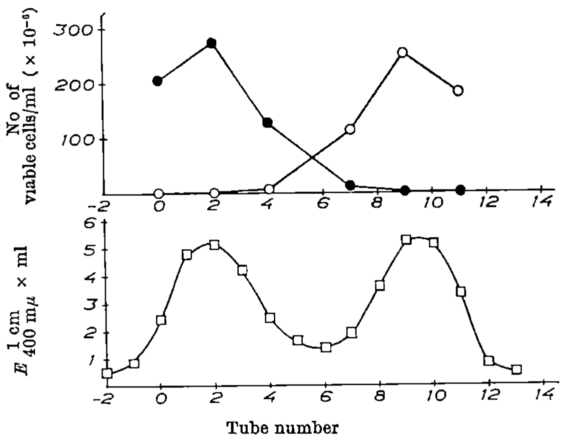

Fig 2 Counter-current distribution of a mixture of *E coli ML* 3081 and *E coli K* 12 *C* (*Hfr*) in phase system (D_5^{48}–PEG_4^{6000}), containing 0 06 *M* sodium chloride Cells cultured and washed as for Fig 1 1 ml samples of *ML* 3081 and *C*(*Hfr*), each of *E*(1 cm, 400 mμ) = 26 0, added to tube No 0 Twelve transfers carried out Lower graph, variation in *E*(1 cm, 400 mμ) × total volume of cell/phase system mixture per tube (7 5 ml) with tube number Upper graph, variation in viable count on *EMB* agar plates with tube number Volume of bottom phase 2 5 ml and of top phase 5 0 ml, of which 0 5 ml kept stationary Total volume per tube therefore 7 5 ml and stationary volume 3 ml. A hand-operated train of 20 glass tubes of the type described by Raymond (ref 6) (obtained from E-C Apparatus Co, Swarthmore, Penn, U S A) was used in this experiment, which was carried out at room temperature (20–23° C)
●, lactose +ve colonies, ○, lactose –ve colonies

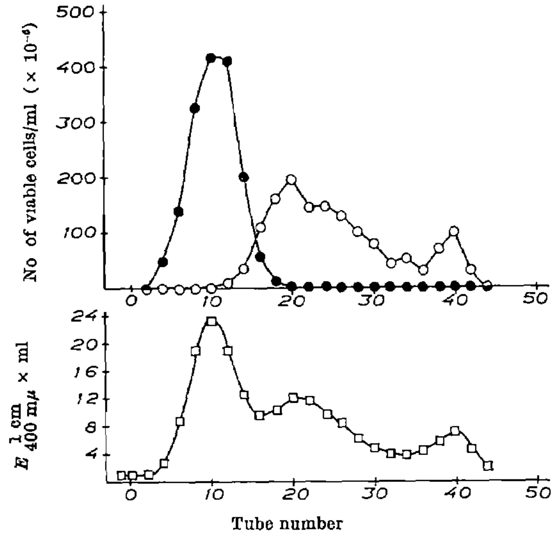

Fig 3 Counter-current distribution of a mixture of the *E coli K* 12 strains *W* 1177 (F^-) and 58/161 (*Hfr*) in phase system (D_5^{48}–PEG_4^{6000}) in the absence of sodium chloride Cells cultured and washed as for Fig 1 5 ml samples of *W* 1177 and 58/161, each of *E*(1 cm , 400 mμ) = 40 0, added to tube No 0 Forty-five transfers carried out Lower graph, variation in *E*(1 cm , 400 mμ) × total volume of cell/phase system mixture per tube (20 7 ml) with tube number Upper graph, variation in viable count on *EMB* agar plates with tube number Volume of bottom phase 9 5 ml and of top phase 11 2 ml , of which 0 5 ml kept stationary Total volume per tube therefore 20 7 ml and stationary volume 10 ml An automatically operated train of glass tubes of the type due to Craig (ref 1) was used in this experiment, which was carried out at room temperature (20–23° C)
●, lactose – ve colonies, ○, lactose + ve colonies

It can then be seen that it is possible to obtain a partial fractionation of cells from a mixture of bacteria which have different distribution patterns in the phase system merely by a one-step procedure To obtain a more complete purification of the cells of one particular type of bacterium from such a mixture, this mixture can be subjected to counter-current distribution The straightforward counter-current procedure, where the top phase is transferred and the bottom phase kept stationary, cannot, however, be used for bacterial cells, as they, in common with other whole cells, are usually to some extent adsorbed to the interface Instead, the whole bottom phase, the interface and a small layer of the upper phase above it can be kept stationary, while the rest of the upper phase is transferred[2] Alternatively, a small layer of the bottom phase, the interface and the whole of the top phase may be transferred, while the rest of the bottom phase is kept stationary In either of these cases, distribution of the particles occurs effectively between the interface and that phase which is moving relative to it

Several mixtures containing two different types of bacteria have been fractionated by this method of counter-current distribution, the results of two such experiments being illustrated in Figs 2 and 3 In both these experiments, the two bacterial types were cultured and washed separately and then mixed, together with phase system, in the first tube of the distribution chain The choice of pairs of bacteria for these two experiments was determined not only by differences in behaviour in phase system but also by the necessity of distinguishing between the members of each pair in a convenient fashion. This latter requirement was met by selecting pairs, one member of which could ferment lactose, and was therefore lactose-positive, while the other could not ferment this substance, and was therefore lactose-negative It was then possible to distinguish between the two by means of the well-known procedure in which bacteria are plated out on agar containing both lactose and indicator (*EMB* agar) As the result of acid production during lactose fermentation, lactose-positive colonies appear dark red when grown on this agar, whereas the lactose-negative remain light pink

From Fig 1, it is clear that in phase system (D_5^{48} – PEG_4^{6000}), the majority of *E coli ML* 3081 cells (lactose-negative) are found in the top phase in the presence of 0 06 *M* sodium chloride, while under these conditions *E coli K* 12 *C* (*Hfr*) (lactose-positive) is found either at the interface or in the bottom phase It should therefore be possible largely to separate a mixture of these two in the presence of this concentration of salt in one step, assuming that the distribution of each is unaffected by the presence of the other Alternatively, complete separation should be obtained by counter-current distribution after only a small number of transfers To demonstrate this, the experiment illustrated in Fig 2 was performed Here, the interface was kept stationary At the conclusion of the experiment it was possible, as described above, to determine the nature and proportion of the bacteria in each tube of the train by plating out on *EMB* agar From the plating results, it is clear that tubes 0–4 and 7–11 of the extraction train contained virtually uncontaminated samples of *K* 12 *C* (*Hfr*) and *ML* 3081 respectively

It is also possible to fractionate mixtures of bacterial cells which have distributions which are much more similar to each other than those of *ML* 3081 and *K* 12 *C* (*Hfr*) Thus, mixtures of the *E coli K* 12 strains *W* 1177 (F^-) (lactose-negative) and 58/161 (*Hfr*) (lactose-positive), the distributions of which are shown in Fig 1, can also be successfully separated by the counter-current procedure From Fig 1 it can be seen that a greater portion of the male cells than of the female cells partition in favour of the top phase of the (D_5^{48} – PEG_4^{6000}) system when no salt is present This implies that it is possible to separate the two strains using a stationary interface, if a sufficient number of transfers is carried out Fig 3 represents the results of an experiment carried out in this manner From the viable counts on *EMB* agar it is apparent that the two cell types were largely separated in this experiment One may assume that, with a larger number of transfers, complete separation could have been achieved The reason for the asymmetric distribution of the *Hfr* cells is under investigation

These results indicate, then, that different types of bacteria frequently have different patterns of distribution in the dextran/polyethylene glycol system It would seem that these distribution patterns, each of which can be expressed as a phase-interface distribution ratio, G_i, can be maintained through a number of transfers in the counter-current apparatus, implying in particular that adsorption of cells to the interface is reversible[2] Furthermore, the distribution of one type of bacterium seems not to be noticeably affected by the presence of another with a different sort of distribution It can be noted here that comparison of viable counts of untreated bacteria and of bacteria which had been subjected to counter-current distribution indicated that treatment with phase system did not apparently have any deleterious effect on the viability of the bacterial cells

It is of interest that even very similar strains, such as the *E. coli K* 12 strains *W* 1177 and 58/161, are distributed in manners which are sufficiently different to allow mixtures of the two strains to be separated by the counter-current procedure. *E. coli K* 12 strains of opposite sex do not seem always to have different distribution patterns, however. For example, as mentioned before, the *E. coli K* 12 female strain *C* 600 is distributed in a very similar fashion to the *E. coli K* 12 male strains 58/161 and *C*. A more detailed study of the behaviour of sex strains in aqueous polymer phase systems and of the influence of surface properties on the distribution of bacteria in these systems is in progress.

We wish to thank Prof. A. Tiselius for his interest in this work. Financial support has been received from the Department of Scientific and Industrial Research in the form of a research fellowship (to G. D. B.), and from the Swedish Technical Research Council.

EFFECT OF TEMPERATURE DURING GERMINATION ON THE CRYSTALLINE TYPE OF STARCH IN SOYBEAN SEEDLINGS

By DR. SUSUMU HIZUKURI, MISS MICHIKO FUJII and PROF. ZIRO NIKUNI

Institute of Scientific and Industrial Research, Osaka University

THE crystalline structure of native starch granules is not identical, and the three main types, the *A*-, *B*- and *C*-types[1], are known. The *U*-type, which has been found recently in *Ulva expana* starch[2], is an exceptional type. The *A*-type has been found mainly in cereal starches, the *B*-type in tuber starches, and the *C*-type in bean and root starches. Some exceptional cases have been found as, for example, in amylomaize (*B*-type)[3], wrinkled pea (*B*-type)[4] and *Colocasia antiquorum* (*A*-type)[5]. The *C*-type is a transition type between the *A*- and *B*-types and many varieties are known, some resembling the *A*-type (*Ca*-type), some being intermediate (*Cc*-type) and some resembling the *B*-type (*Cb*-type). A transition series from the *A*-type (rice) to the *B*-type (potato) through various *C*-types has been observed by Nikuni *et al.*[6,7]

Some hypotheses have been proposed as to why these various structural modifications occur, but this important problem has not been elucidated. We tried to attack this problem by studying the effect of environmental conditions on crystallization, using amylodextrin (short-chain amylose) as test material[8,9]. It was shown that the crystalline type of amylodextrin obtained depends entirely on crystallization conditions such as the temperature of crystallization[9], the concentration of amylodextrin[8] and the kind and concentration of inorganic ions in the mother liquor[8].

In this article, the effect of temperature on the crystalline type of starch in living plants is reported.

Mature soybeans (*Glycine soja*) contain practically no starch, though starch is produced during the germination period to the extent of several per cent of the weight of the seedlings[10,11]. Therefore, seedlings germinated at different temperatures were very suitable material for this work.

Batches of 50 gm. of soybeans were soaked in water at various constant temperatures (10–40° ± 0.5° C.—the temperature-range at which germination is possible). They were kept in a thermostat at these same constant temperatures for 24 hr., or for 48 hr. when the temperature was below 13.5° C. Then the soaked beans were transferred to wet purified cotton beds in deep Petri dishes (12 cm. in diameter and 5 cm. deep). Beans were germinated in the dark, keeping the thermostat at the same fixed temperatures. It took 3–10 days, depending on the temperature, for seedlings to germinate. During incubation, the seedlings were washed with water at the various temperatures and transferred carefully and quickly once or twice a day to new beds to prevent bacterial infection and to provide sufficient humidity. The water content of the cotyledons was 59–64 per cent and that of hypocotyls was 88–92 per cent.

These parts were homogenized with cold water (about 5° C.) for 6 min. in a homogenizer. The homogenate was filtered through filter paper (Toyo Roshi No. 2), with suction. Starch granules were small enough to pass through the filter paper (0.3–3.5μ in diameter) and were thus separated from the cell debris. The residual cell debris were homogenized twice more in the same way. The resulting filtrates were combined and centrifuged at 3,500 r.p.m. for 5 min. The starch fraction, which sedimented, was washed repeatedly with cold water, and finally with methanol, and was then dried to about 20 per cent moisture content. The resulting starch preparation was examined in an X-ray diffractometer. The X-rays used were nickel filtered copper radiations.

The results showed that the crystalline type of the starch obtained from the cotyledons and hypocotyls of soybean seedlings varied greatly with the temperature at which germination took place. A transition series from the *B*-type to one very similar to the *A*-type (*Ca*-type) was obtained with elevation of the germination temperature. The *B*-type appeared at germination temperature below 13.5° C., the *Cb*-type at 16° C., the *Cc*-type at 22° C., and the *Ca*-type at or above 28° C. There was no difference in the type of the starch in the cotyledons and hypocotyls of the same seedlings.

To investigate a mixed type of starch, an incubation was carried out at alternating temperatures. Thus, soaked beans were kept at 32° C. for the first 10 hr. and then the Petri dish was transferred to a 13.5° C. thermostat for the next 14 hr. This altera-

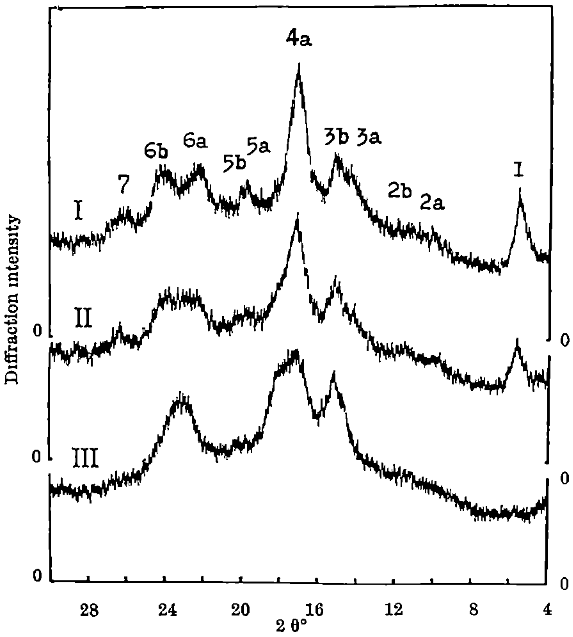

Fig. 1. X-ray diffractometer patterns of starch in soybean seedlings germinated at various constant temperatures. Germination temperature: I, 13.5° C (*B*-type); II, 22° C (*Cc*-type); III, 30° C (*Ca*-type, faint 1-line seen)

tion of temperature was repeated five times during the 5-day period of incubation. The starch obtained from these seedlings was the *Cc*-type, which corresponded to that formed at the intermediate temperature of 22° C. This is further evidence for the idea in ref. 7 that the *C*-type is a mixture of the *A*- and *B*-types.

Typical X-ray diffractometer patterns are shown in Fig. 1. The relation between the diffractometer patterns and the temperature are exactly reproducible, in the same batch of soybeans. Patterns of starch from younger and older seedlings at the same temperature were identical.

This relation between the crystalline type of native starch and the germination temperature coincided with the relation between the crystalline type of amylodextrin and the temperature of crystallization which was reported in ref. 9.

These facts indicate that the crystalline type of native starch is not always decided by the botanical classification of the plant and that it is very much affected by the environmental conditions during the formation of the starch. In fact, some variations in crystalline type have been found in peas[12], mung beans (*Phaseolus aureus*)[13] and sweet-potatoes[14].

INDUCTION OF A LIGHT REQUIREMENT FOR THE GERMINATION OF LETTUCE SEED BY NARINGENIN, AND ITS REMOVAL BY GIBBERELLIC ACID

By Dr. I. D. J. PHILLIPS

Commonwealth Scientific and Industrial Research Organization,
Irrigation Research Station, Griffith, New South Wales

NARINGENIN (5,7,4′-trihydroxyflavanone) has recently been isolated from dormant buds of peach[1], with the suggestion that it is a plant growth-inhibitor playing a functional hormonal role in the control of dormancy[2]. I have been examining some effects of naringenin on several growth and dormancy systems, during the course of which it has become apparent that naringenin exhibits certain properties very similar to that of coumarin, another well-known naturally occurring plant growth-inhibitor.

One of the most interesting effects of coumarin on plants is the observation that it can induce a light requirement for germination in varieties of lettuce that are normally not light-requiring[3], and that such an induced requirement can be removed by gibberellic acid[4]. Thus it was decided to investigate the possibility that naringenin, too, could induce a light requirement by non-dormant lettuce seed, despite its structure being very different from that of coumarin.

Commercially supplied lettuce seed (var. Great Lakes) was used in the following experiments. The seeds were allowed to germinate in either darkness or light in 9 cm. diameter Petri dishes on Whatman 1/64 in. seed-test papers, which had been moistened with either 4 ml. distilled water in the controls, or with 4 ml. test solution. Light was supplied by a bank of 'Daylight' fluorescent tubes 88 cm. above the Petri dishes, and the temperature was maintained at a constant 21° ± 1° C. Germination was allowed to proceed for 48 hr., at the end of which time the percentage germination per treatment was determined. There were approximately 300 seeds in each treatment.

Germination of seeds in a range of aqueous naringenin concentrations revealed that, up to 20 mgm./l. naringenin, there was no inhibition of germination

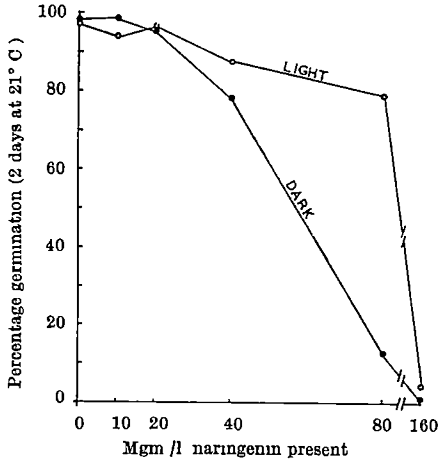

Fig 1 Result of germinating seeds of Great Lakes lettuce (approximately 300 seeds per treatment) at 21° ± 1° C, in aqueous solutions of naringenin, or in water Open points, seeds allowed to germinate in light, closed points, seeds germinated in darkness

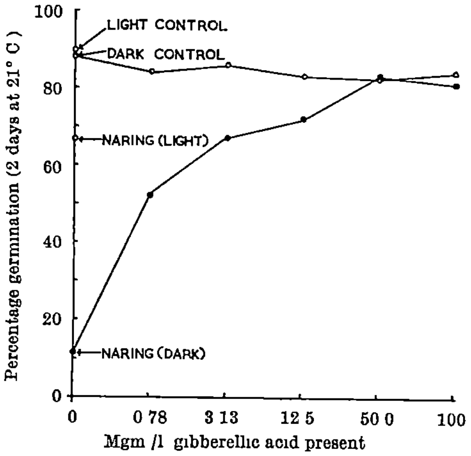

Fig 2 Effect of a range of concentrations of gibberellic acid on the dark-inhibiting effect of an 80 mgm /l solution of naringenin, on the germination of Great Lakes lettuce seed O, gibberellic acid alone, ●, gibberellic acid plus naringenin

in either light or dark, but that at 40 mgm /l, and particularly at 80 mgm /l there was a suppression of germination, with much more inhibition in darkness than in light (Fig 1) This result has been fully confirmed in other experiments Consequently naringenin behaves similarly to coumarin in this respect

The effect of a range of gibberellic acid concentrations on the dark germination of seeds in a solution of 80 mgm /l naringenin was measured, and the result shown in Fig 2 It can be seen that gibberellic acid reverses the light requirement induced by naringenin, and that the extent of the reversal is a function of the ratio of the number of gibberellic acid molecules present to molecules of naringenin It might be said, therefore, that there is a competitive relationship between gibberellic acid and naringenin in their effects on lettuce-seed germination in darkness This again is similar to what has been found for coumarin[4]

It is interesting that two such chemically dissimilar compounds as coumarin and naringenin have the same effects on lettuce-seed germination, and that these effects can be counteracted by gibberellic acid However, both compounds are naturally occurring plant-growth inhibitors, and there is an accumulation of evidence that such substances may be active in the control of dormancy It is conceivable that both are active as inhibitors of growth in dormant tissues by acting as competitive inhibitors of endogenous gibberellin of the tissues This hypothesis is supported by the evidence that gibberellins are present in plant tissues[5], and that inhibitors are found particularly in dormant organs However, in work on auxin-antagonists it has generally been found that where such a compound competitively inhibits auxin then the 'competition' for sites of action between antagonist and auxin can be related to chemical structure[6] Perhaps in the case of coumarin and naringenin there is a common basis in their molecular structures for their similar physiological effect, but elucidation of what that basis is must wait until the effects of other compounds on dormancy systems are investigated to enable a closer comparison to be made.

It is possible that such apparent competitive inhibition of gibberellic acid by either coumarin or naringenin as reported here may not be a true, simple competition of molecules for 'sites of action', as is the case for competitive enzyme inhibitors If this were so, then it might be that a wide variety of divergent types of compound will behave similarly to coumarin and naringenin, with no common structural basis to explain the similarity However, it has been reported[7] that any change in the molecular structure of coumarin, as brought about by substitution, will cause a decrease in the inhibiting effect of the molecule This would seem to indicate that there is some specific molecular requirement for inhibitory activity

CHLOROGENIC ACID: AN ALLERGEN IN GREEN COFFEE BEAN

By Dr. S O FREEDMAN, J KRUPEY and A H SEHON

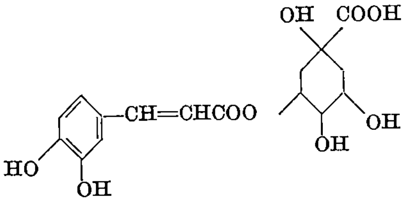
McGill University Clinic of the Montreal General Hospital and Departments of Biochemistry and Chemistry, McGill University

IT is well known that workers in the coffee industry frequently develop bronchial asthma, rhinitis or dermatitis on exposure to the fine dusty powder which fills the air of the factory as the chaff is mechanically stripped from the raw bean prior to roasting Previous investigations[1] showed that all workers so affected gave large positive immediate type intradermal reactions to aqueous extracts of green coffee chaff and green coffee bean Skin-sensitizing antibody (reagin) to green coffee was shown to be present in the sera of these allergic workers by passive transfer (Prausnitz–Kustner) experiments Extracts of roasted coffee, on the other hand, gave minimal or negative reactions on both direct and passive transfer testing

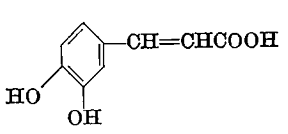
Chlorogenic acid, a compound of quinic and caffeic acids, is one of the major water-soluble constituents of green coffee, accounting for 5–8 per cent of the dry weight of the bean[2] It was first obtained in crystalline form from green coffee beans by Gorter[3] On the basis of a ferric chloride colour reaction, he concluded that this compound was widely distributed in the leaves and seeds of numerous plants, but it is now known that Gorter's test is not specific for chlorogenic acid since ferric chloride will give a colour reaction with most phenolic compounds Nevertheless, chlorogenic acid has been shown to be present in significant quantities in apples, pears, carrots, beans, celery, lettuce, cucumber, cabbage, plums, cherries, sweet potatoes and tobacco[4-8] Joslyn and Ponting have suggested that the darkening of certain cut fruits on exposure to air is due to the oxidation of chlorogenic acid to a quinone, rather than to the oxidation of true tannins[9]

The purpose of the present work was to identify the chemical nature of the allergen(s) present in green coffee bean The aqueous extract investigated was highly allergenic, producing a markedly positive wheal and erythema response on direct skin testing with 0 02–5 ml of a solution containing 5 mgm /ml and a positive passive transfer reaction at a serum dilution of 1 3,200

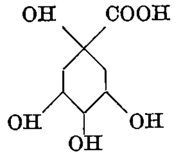
The aqueous extract of green coffee was fractionated by chromatography on dextran gel ('Sephadex *G*-25', purchased from Pharmacia, Uppsala). Forty-five fractions were collected and tested for allergenicity by the passive transfer method The middle fractions (18–29) gave strongly positive passive transfer reactions, while the remainder of the fractions gave minimal or negative reactions All the allergenically active fractions were coloured brown and gave a green colour reaction with ferric chloride, while the allergenically inactive fractions were colourless and gave a negative ferric chloride test These observations suggested that phenolic compounds were present in much higher concentrations in the allergenically active fractions



Chlorogenic acid (3-caffeoylquinic acid)



Caffeic acid



Quinic acid

A systematic evaluation of the known phenolic compounds in coffee was undertaken by injecting the suspected compounds into the skins of ten workers known to be allergic to green coffee Only chlorogenic acid produced positive reactions 1 µgm of chlorogenic acid was sufficient to induce a large wheal and flare response with pseudopods in all the subjects tested On passive transfer testing with the sera obtained from five of these workers, as little as 5×10^{-5} µgm of chlorogenic acid was required to elicit a reaction at a site sensitized with 0 05 ml of serum Identical results were found with chlorogenic acid obtained commercially and with chlorogenic acid isolated from the aqueous extract of green coffee by the method of Moores *et al* [2]

Cross-neutralization tests were performed with chlorogenic acid and an aqueous extract of green coffee in order to elucidate the allergenic relationship between these two substances In one series of tests, sites in the skin of normal human recipients were passively sensitized with sera obtained from individuals allergic to green coffee These sites were then challenged in 24 hr by the intradermal injection of 1 µgm of chlorogenic acid On the following day, the same sites were re-challenged with 100 µgm of green coffee extract There were no reactions on re-challenge, indicating that all the antibody directed against the green coffee had been previously neutralized by the chlorogenic acid (Table 1)

Table 1 RESULTS OF CROSS-NEUTRALIZATION EXPERIMENTS

Serum from patients sensitive to green coffee	Initial reactions on passive transfer to 1 µgm of chlorogenic acid	Reactions on rechallenge with 100 µgm of green coffee
P S	+ + + +	–
P S	+ + +	–
A S	+ + + +	–
M C	+ + +	–
W M	+ + +	–

Complete cross-neutralization was also obtained by another technique Chlorogenic acid and the serum of an individual allergic to green coffee were mixed *in vitro* in previously determined neutralizing proportions 24 hr later, this mixture was injected into the skin of a normal recipient Challenge of this same site on the following day with green coffee extract produced no reaction These results would suggest that chlorogenic acid (or chlorogenic acid complexed with other constituents of green coffee) may be the principal allergen in green coffee

In an attempt to identify the allergenically active portion of the chlorogenic acid molecule, passive transfer tests were performed with caffeic and quinic acids No positive reactions were obtained However, when a passive transfer site previously sensitized with allergic serum was injected with a mixture of caffeic and quinic acids in equimolar proportions at a relatively high concentration (300 µgm /ml. and 320 µgm /ml respectively), and the same site was re-challenged in 24 hr with 1 µgm of chlorogenic acid, the expected reaction was partially inhibited Similarly, when a solution of quinic and caffeic acids at the same high concentrations was mixed with allergic serum prior to injection, there was partial inhibition of the passive transfer reaction to chlorogenic acid

In order to explore the possibility of developing an *in vitro* test for precipitating or hæmagglutinating antibodies to green coffee, rabbits were immunized with a mixture of green coffee extract and Freund's adjuvant A positive precipitin test was obtained when the rabbit antisera were treated with green coffee extract or with a solution containing both chlorogenic acid and human serum albumin In the hæmagglutination procedure, green coffee extract was linked to rabbit erythrocytes using the *bis*-diazotized benzidine technique described by Gordon, Rose and Sehon[10] Hæmagglutinating antibodies against green coffee were detected in the rabbit antisera up to a dilution of 1 1,000,000 Chlorogenic acid, when used in the standard hæmagglutination procedure, produced non-specific hæmagglutination of rabbit erythrocytes and was therefore unsuitable for investigation by this method The hæmagglutination reaction with green coffee was completely inhibited by the whole extract and by the previously described allergenically active coloured fractions obtained on chromatography

No precipitation was obtained with human allergic sera, but one of the human sera so far tested was found to contain hæmagglutinating antibodies to green coffee up to a dilution of 1 1,280

In conclusion, it would appear that chlorogenic acid may be the principal allergen in green coffee The fact that an immediate skin reaction can be produced by a compound of low molecular weight would suggest that chlorogenic acid acts as a hapten in human skin or mucous membranes A simple phenolic compound of low molecular weight has thus been identified as a major allergenic component of a plant material responsible for human atopic disease Because polyphenolic compounds are widely distributed throughout the plant kingdom, it is possible that these observations may be useful in the search for the allergenic constituents of other foods, pollens, dusts or moulds

RESPONSE OF CHLOROPLAST CYTOCHROMES TO LIGHT AND SUBSTRATES

By Prof H LUNDEGÅRDH

Penningby, Sweden

THE introduction of a new spectrophotometric technique for investigation of oxidation-reduction processes in living material has promoted our knowledge of the respiratory enzymes in plants, for example, roots of cereals, and yeast[1–4] The presence and activity of a number of cytochromes, flavoproteins and enzymes linked to pyridine nucleotide (PN) has been demonstrated in live cells and in mitochondria and observations of the steady-state changes at variation of the oxygen supply are revealing certain general features of the structural organization of the respiratory unit[3,4]

Chloroplasts, too, contain cytochromes, which are spectroscopically very similar to those in mitochondria[5] Hill and Scarisbrick[6] found in chloroplasts a cytochrome *f*, characterized by an α-band at about 554 mμ and a prosthetic group similar to that of cytochrome *c* Its spectral bands are very close to those of cytochrome c_1 in mitochondria The cytochromes *c* and c_1 are predominantly oxidized in normally respiring mitochondria and are reduced rapidly in the absence of oxygen Cytochrome *f* remains partially reduced in the dark and the α-band at 554 mμ may be observed easily in de-chlorophyllized chloroplasts I showed in 1954 that it is oxidized if the chloroplasts are exposed to light[5] Similar observations of the oxidation by light of a cytochrome of *c*-type were made in a number of photosynthetic micro-organisms[8] During my work on the response of cytochrome *f* to light I also observed partly opposite reactions of a cytochrome *b* (ref 5) Hill reported[9] the presence of a cytochrome b_6 with an α-peak at about 563 mμ Finally, a cytochrome b_3 was distinguished with an α-peak of the reduced enzyme at about 559 and a γ-band at 429 mμ (ref 10) This cytochrome is very similar to a cytochrome b_3, which is probably a regular constituent of the respiratory unit in plant tissues Very little has hitherto been reported regarding an eventual response of the *b*-group in chloroplasts to light The whole problem thus called for a re-investigation, particularly in connexion with the recent discoveries regarding photophosphorylation

Arnon[11] first showed the actual existence of a light-induced phosphorylation in chloroplasts, linked, in his results, with the mentioned interaction of cytochromes in the light response According to Arnon's scheme of photophosphorylation, chlorophyll converts light-energy in a stream of electrons which are passing through a cycle of redox-enzymes, among these, cytochromes The cytochromes in chloroplasts are figured co-operating in phosphorylation in much the same way as in mitochondria

Chloroplasts also produce reduced pyridine nucleotide[11,12] (PN, preferably triphosphopyridine nucleotide (TPN)) and, simultaneously, oxygen It is commonly assumed that PN is reduced by the electrons expelled from the excited chlorophyll plus protons (H^+) from water The remaining OH^- ions may lose their electrons to the cytochrome system and simultaneously produce oxygen and water Water thus acts as a bridge connecting the reducing (Chl → TPNH) and oxidizing (cytochromes → Chl) moieties of the cycle The net effect of the water bridge is to move electrons in the direction of the potential gradient and protons in the opposite direction The formation of adenosine triphosphate (ATP) and reduced pyridine nucleotide (PNH) takes place in the pigmented grana[13] The reduction of $CO_2 + H_2O$ to carbohydrate (CH_2O) is a dark chemo-synthetical process which takes place in the non-coloured stroma of chloroplasts.

In continuing my work on the response of chloroplast cytochromes to light I have kept in mind the results of my recent investigations on steady-state relations of the respiratory enzymes in baker's yeast[14]. It was shown that the intensity of respiration and the apparent velocity of reduction of the involved cytochromes are synchronously lowered on the addition of ATP, and raised on the addition of ADP + PO_4. This is what would be expected if the steady-state balance ADP + $PO_4 \rightleftharpoons$ ATP were moved in one direction or the other on changing the concentration of the substrates, and if the process of phosphorylation serves as an efficient path of electron transfer between two cytochromes. A displacement of the steady-states of pyridine nucleotides may also have an influence. Because in chloroplasts both pyridine nucleotides and adenosine phosphates are directly or indirectly involved in the transfer of electrons between chlorophyll and water it may be expected that a rise of concentration of one of these substrates will exert a significant influence on the light response.

Cultivated and wild plants, including spinach, wheat, clover (*Trifolium repens*), *Agrostis stolonifera* and *Chenopodium album* served as experimental material. The leaves were ground with sand and 0·3 *M* sodium chloride with 0·02 mol. *tris* buffer and the brei squeezed through double cheese-cloth. For clover and spinach homogenization for 5–7 sec. also gave good results. Coarse particles were removed by centrifugation for 1 min. at 100–200*g*. The supernatant was spun for 7 min. at 1,400*g* and the pellet, containing the whole chloroplasts, was washed and re-centrifuged in 0·3 *M* sodium chloride. All manipulations, including the spectrophotometric observations, were carried out at approximately 0° C. The final suspension in 0·3 *M* sodium chloride contained about 30 mgm. chloroplasts (dry weight) in 10 ml. solution (0·3 per cent).

For the spectrophotometric analysis 10-mm. cuvettes were provided with an inset of gilded brass leaving a central 2-mm.-wide slit. The cuvettes were placed in a holder about 30 mm. from the entrance slit of a Bausch and Lomb monochromator. The enclosed portion of the suspension (2 × 10 × 10 mm.) was illuminated by focusing on it the straight band of a tungsten lamp (through a thick plate of heat-absorbing glass). By means of a suitable shutter the light was turned on immediately after the start of the spectrophotometric recorder. Two instruments of my own construction were used for this investigation. One instrument moves the wave-length screw 2 mμ, in intervals of 0·33 or 0·5 sec. and yields a record (high-speed pen recorder) of the region 540–570 mμ in 5·0–7·5 sec., which is repeated in intervals of 10 sec. The second instrument is of the scanning type and moves the wave-length screw 540–570 mμ in 0·25 sec. with immediate repetition of the movement. An oscillographic recorder yields 180 complete spectrograms in 1 min.

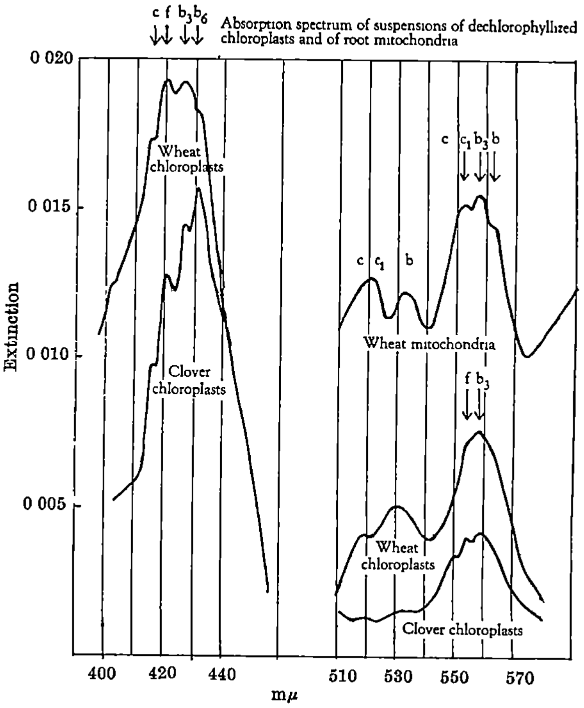

Fig. 1. Reduced cytochromes (dithionite) in chloroplasts of wheat and clover, from which the chlorophyll was removed by treatment with alcohol, compared with cytochromes in mitochondria

Occurrence and Percentage of Cytochromes in the Chloroplasts

Because the state of oxidation-reduction of the cytochromes is varying according to light intensity and availability of co-factors and substrates, measurements of the amplitudes of the reduced α-bands under varying conditions are revealing not only the types of involved cytochromes, but also the reacting quantities. Direct spectrograms of chloroplast suspensions or whole leaves show band-peaks or elevations at 550, 554, 556–558 and 562–564 mμ, corresponding to cytochromes *c*, *f*, b_3 and b_6. The close relation of cytochrome b_3 to a corresponding cytochrome in roots and of b_6 to the cytochrome *b* in mitochondria appears from records of the γ-region of de-chlorophyllized chloroplasts in dithionite (Fig. 1). Peaks are appearing here at 416 (*c*), 420 (*f*), 426–427 (b_3) and 430–432 mμ (b_6). The relation in height between the γ-bands and the α-bands amounts to 4–7, or about the same as in wheat roots and in preparations of cytochromes *c*, *f*, c_1 and *b*.

After removal of the chlorophyll with alcohol and re-suspending in 0·3 *M* sodium chloride, chloroplasts and whole leaves show a reduced band of cytochrome *f* which is further increased in dithionite. The weak bands at 416 and 550 mμ are not always clearly recorded, and the possibility cannot be *a priori* excluded that contaminations from protoplasm are at work. A comparison between the spectrograms from whole leaves and from suspensions of chloroplasts does not support this possibility, however, and it must be concluded that chloroplasts contain certain quantities of a cytochrome, the bands of which lie close to those of cytochrome *c*. The complete sets of cytochromes in chloroplasts and mitochondria are thus surprisingly similar to one another even if the proportions are different (see Fig. 1). Besides the above-mentioned differences, roots contain about 2–4 times as much cytochrome *b* as cytochrome c_1, whereas in wheat chloroplasts the relation b_3 to *f* is about 1, and b_6 is less abundant than *b* in plant mitochondria. A suspension of chloroplasts of clover contains 3–5 times as much cytochrome as a yeast suspension of equal concentration.

For calculation of the percentage of cytochrome in chloroplasts, measurements were made at the following wave-length intervals 550–542, 554–542, 558–542, or 558–570 and 564–570 mμ. The calculations are approximate, primarily because of the partial overlapping of the bands of *c* and *f* and of *f* and b_3. About 25 per cent of the α-band of *f* covers the α-band of b_3.

In 0.3 per cent chloroplast suspensions the amplitude of variations in the state of oxidation-reduction in maximum amounted to about $\varepsilon = \pm 0.03$, corresponding to about 2.5 per cent cytochrome $(c + f + b_3 + b_6)$ calculated per unit dry weight. Leaves of clover contain higher quantities than those of wheat seedlings. It was assumed that the group $c + f$ has a molecular weight of 15,000 and the group $b_3 + b_6$ 30,000 (ref. 15). These calculations are, of course, only tentative. De-chlorophyllized chloroplasts yield lower values, or 0.7 per cent, probably because some cytochrome is extracted or disorganized in alcohol. Alcohol also removes most of the lipids, which, together with chlorophyll, contribute about 50 per cent of the solid substance of the chloroplasts. Per unit of iron, group *c*–*f* and the group b_3–b_6 have about equal percentages of the total quantity of cytochromes.

For comparison, determinations were also made on mitochondria from wheat roots, yielding 0.5–1.0 per cent cytochrome per unit dry weight (earlier figures are somewhat higher, because it was then calculated with a molecular weight of cytochrome $b = 60,000$). We thus arrive at the conclusion that chloroplasts contain 2–3 times more cytochrome than mitochondria from the same plant. The observed rapid interaction of chlorophyll and cytochromes, and the fact that the grana are the sites of photophosphorylation, support the conclusion that all cytochromes are structurally linked to chlorophyll.

Response to Light

According to current opinions (see above) the excited chlorophyll maintains a flux of electrons through a cycle of redox enzymes and co-factors making up an internal circuit and, if $H^+ + e^-$ is consumed, water the external circuit. Warburg discovered [16] that chloride was acting as a co-factor. Chloride ions may here possibly act in a similar way to salt ions in respiration, in other words facilitating the shuffling of electrons over a water bridge. In photosynthesis the chlorophyll may be thought of as operating in the same way as the cathode of a photocell, expelling electrons in light, like many other dyes[17]. The conversion of electrical energy into chemical energy, namely, the synthesis of reduced pyridine nucleotide and high-energy phosphate, occurs at a few intermediate points.

The structural organization of the respiratory unit of mitochondria is mirrored in a rhythmic course of reduction at removal of the oxygen[2,3]. Reduction invariably starts with the enzymes of highest oxidation potential (cytochrome oxidase (a_3) and cytochrome *c*). After a gap of 1–2 sec (in yeast at room temperature) or a few minutes (in wheat roots) reduction of cytochrome *b* begins. Observations of the time course of reduction by means of rapidly recording spectrophotometers[4] thus serve as a useful tool for investigating the individual response of the single respiratory enzymes to environmental influences. At re-oxidation the time course is reversed, now starting at the enzymes of the highest reduction potential, but the rhythm is here less clearly observed, because re-oxidation, as a rule, proceeds very quickly.

Chloroplasts have no cytochrome oxidase and do not respire[11]. Their electronic state in darkness thus corresponds to that of mitochondria which lack oxygen. Light converts chlorophyll into an oxidase which attracts electrons from the adjacent cytochrome *f*. Electrons are now flowing through the whole cytochrome system and continuously replaced by those expelled from the excited chlorophyll. Each link in the cycle is steered by an on-reaction and an off-reaction $\left(\frac{e^-}{\text{on}} \rightarrow \text{cyt} \rightarrow \frac{e^-}{\text{off}}\right)$ and the single enzymes, at least some of them, are interspersed by speed-regulating 'factors'. A close observation of the time course might also reveal an individual response. I have in this article restricted myself to observing the sign and magnitude of the response of the cytochromes.

Recent investigations of Witt and co-workers[18] have shown that the immediate activation of chlorophyll may be observed a few milliseconds after turning on the light and also that activation of the water bridge probably starts very rapidly. My own oscillographic records show, in less than 0.1 sec., a rapid rise in extinction of the whole green trough between 540 and 570 mμ. The extinction is highest in the region 555–560 mμ, but this broad band does not belong to a cytochrome. A possible reactant is catalase. The role of catalase in chloroplasts has been widely discussed, but we cannot go into this problem here. The possibility of catalase guiding the de-ionization of OH^- and transference of electrons to cytochrome b_3 deserves serious consideration.

The response of the cytochromes to light is considerably slower than the initial reaction already mentioned. In my first publication the response was measured about 10 sec. from the start[5]. New records in time-intervals of 0.3–0.5 sec. afforded values down to 2 sec. but most of them centred around 6–8 sec.

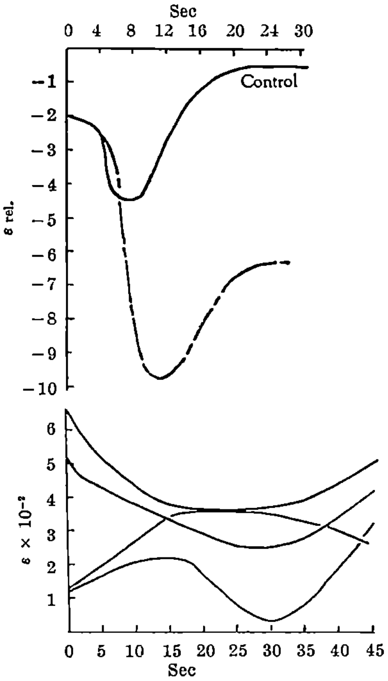

Fig. 2. Above, the response of cytochrome *f* to light. Washed chloroplasts of *Chenopodium album*. Upper curve in 0.3 *M* NaCl, lower curve 0.3 *M* NaCl + 0.015 *M* ADP as sodium salt. Below, response of chloroplast cytochromes of *Trifolium repens* to light. The light was in both cases turned on at 0 sec.

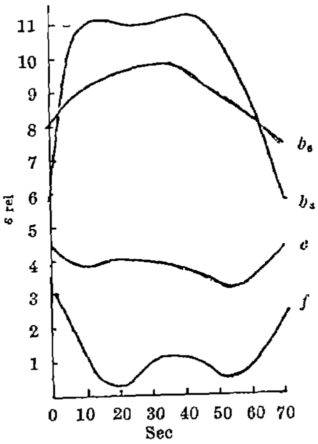

Fig 3 Response of chloroplast cytochromes of *Agrostis stolonifera* to light Whole leaves The light was turned on at 0 sec

(Fig 2) The existence of a starting lag was observed in all plants, both in whole leaves and in chloroplast suspensions In a number of cases different starting lags were observed regarding cytochromes *f* and b_3 The oxidation of cytochrome *f* in light started earlier than the oxidation of cytochrome b_3 (and b_6) by cytochrome *f* This result refers to washed chloroplasts and shows a more rapid supply of electrons from TPNH to b_3 and from *f* to chlorophyll than from b_3 to *f*, when phosphorylation is retarded for lack of substrates

Similar to the length of the starting period, the time course of the response to light may vary too All these observations were made on chloroplast suspensions in 0 3 *M* sodium chloride Ageing suspensions sometimes react differently to light and may show either an insignificant response or an increased reduction of the cytochromes instead of oxidation (Figs 4 and 5) Sometimes cytochromes *f* (and *c*) react in an opposite way to the group b_3–b_6 This counter reaction of the *b*-group, which was observed also in 1954 (ref 5), is shown in Fig 3 These observations also show a lowering of the conductivity between the *b*-group (primarily b_3) and the *f* (*c*)-group, a fact reminiscent of the relation between the cytochromes *b* and *c* in mitochondria, which is exposed to a number of influences, for example, inhibition by urethane and antimycin *A* (refs 1 and 19)

Variations in the response to light are always to be expected from a cyclic system in which the individual on- and off-reactions are regulated by interaction with different enzymes or 'factors' Some of the intermediate factors have been tested, for example, flavin adenine mononucleotide (FMN), vitamin K, etc [11] These co-factors are controlling the supply of electrons to the cytochrome system My experiments show that addition of FMN turns a negative response to light (oxidation of cytochromes), into a positive one (reduction in light) This may be explained as follows FMN lowers the resistance to internal transport of electrons from excited chlorophyll to the cytochromes, a result in agreement with observations on photophosphorylation[11] An opposite effect —an increase of the light-induced oxidation of the cytochromes—is observed on addition of ferricyanide This substance is obviously trapping the electrons before they reach the cytochromes, but does not impede the reduction of chlorophyll (Fig 4)

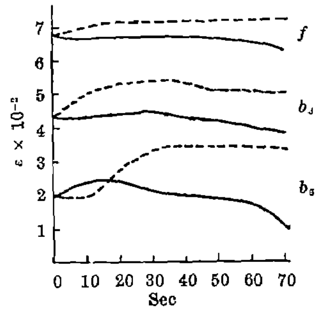

Fig 4 Response to light of unwashed wheat chloroplasts after addition of ferricyanide (10 mgm in 1 ml) The controls (broken curves) show in this experiment an increased reduction of the cytochromes after turning on the light (see text)

Influence of Substrate Factors on the Light Response

In these experiments sodium salts of DPN or DPNH (Sigma, acting similar to TPN and TPNH, but slightly weaker) and ATP or ADP were added in quantities corresponding to 0 01–0 02 *M* After a period of 10–60 min in the dark, the response to light was recorded as above For determination of the dark response to the substrates the recipients were placed in front of the photomultiplier tube. The weak light from the monochromator does not appreciably disturb the steady states

As shown in Table 1, addition of DPN induces increased oxidation of the cytochrome system The opposite effect of DPNH is notably observed as a reduction of cytochrome b_3 The weak response of cytochrome *f* to reducing agents is due apparently to its normally predominant reduction in the dark The results indicate the existence of a steady state between pyridine nucleotide and cytochromes, in which transferring co-factors (FMN, etc) may be involved, according to the scheme in Fig 6 and reaction 1 (see later) A rise in the concentration of PN moves the steady state in one direction, addition of DPNH promotes the reverse reaction The pronounced response of b_3 points to this cytochrome functioning as the switch-board between the reducing (Chl → PN → co-factors) and the oxidizing moieties (cytochromes → Chl) of the cycle

Table 1 DARK REACTIONS EFFECTS OF SUBSTRATES ON THE STATE OF OXIDATION-REDUCTION OF THE CYTOCHROMES CHLOROPLASTS FROM WHEAT SEEDLINGS

Cytochromes	*f* (+*c*)	b_3	b_6
+0 015 *M* DPN	Oxidation	Oxidation	Oxidation
+0 015 *M* DPNH	Weak reduction	Strong reduction	Weak reduction
+0 015 *M* ADP(+PO_4)	Weak oxidation	Weak oxidation	Weak reduction
+0 015 *M* ATP	Reduction	Reduction	Reduction

As to the adenosine phosphates, recent observations on yeast showed that a supply of ADP + (PO_4) accelerates the electron transference, notably from cytochrome *b* to *c* (and c_1), whereas addition of ATP retards it The effects were also observed as an increase or a decrease of the intensity of oxygen consumption It was concluded that variations in the mutual concentration of ADP and ATP cause the steady-state balance ADP + (PO_4) $\rightleftharpoons$ ATP to move forwards or backwards

In the dark chloroplasts the chlorophyll remains saturated with electrons and cannot absorb more from cytochrome *f* This cytochrome consequently remains reduced to a degree which is determined by the total oxidation–reduction balance between PN, PNH, co-factors, and cytochromes Substrate influences will thus, to a certain degree, be reflected in a displacement of the corresponding steady states

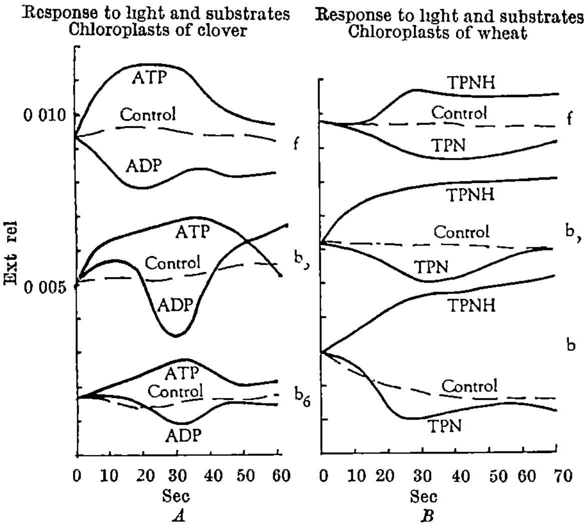

Fig 5*A* Response to light of washed chloroplasts of clover (*Trifolium repens*) in 0 3 *M* NaCl after addition of ATP or ADP (8 mgm in 1 ml) Exposure (at 0 sec) made 40 min after addition of substrates Controls (broken curves) in 0 3 *M* NaCl alone

B Response to light of washed chloroplasts of wheat in 0 3 *M* NaCl after addition of TPN and TPNH (as sodium salts, 6 mgm in 1 ml) Controls (broken curves) in 0 3 *M* NaCl alone

in the dark The response of cytochromes to ADP or ATP in the dark (Table 1) indicates the position of a point 2 of phosphorylation between b_3 (and/or b_6) and *f* (and/or *c*) Changes in the steady state of b_3 and b_6 indicate a point 3 of phosphorylation between these cytochromes (or one of them) and the dehydrogenizing co-factors (see also Fig 6)

The response to light (Table 2 and Fig 5) illustrates a further development of the dark effects, the reactions are still more intensified except in the case of b_6, which responds to ADP or ATP much in the same way as in respiring yeast The rising oxidation of yeast cytochrome *b* on the addition of ATP was interpreted as a retardation of the stream of electrons from dehydrogenases to cytochrome *b* This conclusion may be applied also to the chloroplasts The increased reduction of b_3 of chloroplasts on the addition of ATP indicates the existence of a point 2 of phosphorylation between b_3 and *f*, the inhibition of which retards the off-reaction of b_3 and consequently promotes its reduction The fact that cytochrome *f* is less oxidized in light after addition of ATP is interesting because it indicates the existence between *f* and Chl$^+$ of a point 1 of phosphorylation, which is absent in the transference $a_3 \rightarrow O_2$ in the respiratory chain

Table 2 RESPONSE TO LIGHT AVERAGE EFFECTS OF SUBSTRATES ON THE LIGHT-REACTION OF CHLOROPLASTS OF CLOVER AND WHEAT Period of illumination, 60 sec Spectral records at short intervals Controls without organic substrate showed weak oxidation

Cytochromes	*f* (+*c*)	b_3	b_6
+0 015 *M* DPN	Oxidation	Oxidation	Weak oxidation
+0 015 *M* DPNH	Weak reduction	Reduction	Reduction
+0 015 *M* ADP(+PO_4)	Oxidation	Oxidation	Weak oxidation
+0 015 *M* ATP	Weak oxidation	Reduction	Oxidation

DISCUSSION

The new experiments corroborate my work in 1954 regarding oxidation of cytochrome *f* in light[5] I claimed that "it is feasible to assume that radiant energy transformed into chemical energy may oxidize cytochrome *f* or alternatively a special cytochrome system connected to the chloroplasts and thus create a pool of chemically accessible hydrogen required for up-hill reactions in the path of carbon" It was assumed that the electrons flowing from cytochrome to chlorophyll are brought back again to cytochrome *b* by the transformed light energy Arnon's discovery of photophosphorylation strongly supports this idea of the chloroplast cytochromes acting as a mechanism for transforming electrical energy into chemical energy

The results of the present investigation are in agreement with Arnon's concept of a photophosphorylation and they also emphasize the similarities in enzymic composition of chloroplasts and mitochondria

With regard to Arnon's distinction of a cyclic and a non-cyclic phosphorylation, or, in other words, production of only ATP or of ATP + TPNH, my own results point to the combined activity of a chain of reduction, ending in TPNH, and a chain of oxidation (through cytochromes) producing ATP The following reactions may illustrate the main transferences (cf Fig 6)

$$\mathrm{TPN} + 2\mathrm{H}^{+} + 2\overset{\text{excited chlorophyll}}{\downarrow} e^{-} \xrightarrow{\text{TPN reductase}} \mathrm{TPNH}_2 \qquad (1)$$

$$\mathrm{TPHN}_2 + 2\mathrm{Fe}^{3+} \xrightarrow[\text{dehydrogenases}]{\text{co-factors}} \mathrm{TPN} + 2\mathrm{H}^{+} + 2\mathrm{Fe}^{2+} \qquad (2)$$

$$\mathrm{H_2O} + 2\mathrm{Fe}^{3+} \xrightarrow{\text{catalase ?}} \mathrm{O} + 2\mathrm{H}^{+} + 2\mathrm{Fe}^{2+} \qquad (3)$$

$$\mathrm{Fe}^{2+} + \text{excited chlorophyll} \rightarrow \text{chlorophyll} + \mathrm{Fe}^{3+} \qquad (4)$$

Chloroplasts which are not performing chemosynthesis of carbohydrates only form ATP (Arnon's cyclic phosphorylation) The electrons which are relinquished from the excited chlorophyll are, together with protons from the surroundings, reducing TPN (reaction 1) and are from here (via dehydrogenase co-factors) transferred to cytochrome *b* (reaction 2) Because in reaction 2 the same quantity of protons is released as is consumed in reaction 1, hydroxyl ions are not produced There is consequently no need for eliminating OH^- and producing oxygen The electrons are flowing directly to the cytochromes from reduced pyridine nucleotide without accumulation of anything except ATP

The need of a continuous supply of protons arises if $TPNH_2$ is used for an external purpose, such as the chemosynthesis of carbohydrates Protons are, in this case, continuously pulled from water leaving OH^- ions which would be accumulating in unphysiological quantities unless they are eliminated by reac-

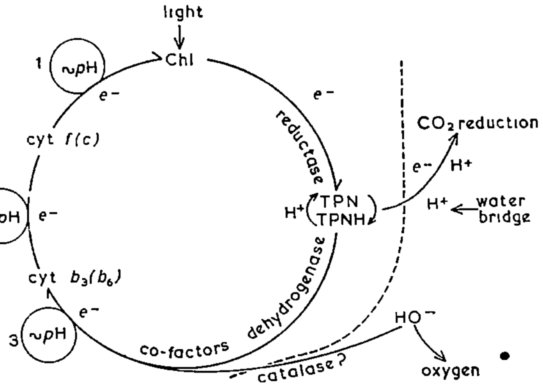

Fig. 6 Scheme of the photosynthesis in chloroplasts The broken line marks the effect of switching carbohydrate synthesis on or off

tion 3 This process implies a de-ionization of OH^- by the hæm enzymes, possibly in co-operation with catalase, leaving reduced cytochrome *b* and oxygen Reaction 3 is similar to the well-known Hill reaction[22], with the experimental difference that in the reaction observed by Hill, electrons from the excited chlorophyll are reducing external ferri-ions (cf trapping of electrons in potassium ferrocyanide (Fig 4)) What is producing oxygen is, however, in this case not the reducing moiety of the cycle but the oxidizing one, namely, the cytochrome system in co-operation with catalase or some other enzyme catalysing the electrolysis of water If electrons are trapped in the reducing moiety the excited chlorophyll will pull electrons from the cytochromes and thus keep the electrolysis of water going The relinquished protons (see reaction 3) are, in the Hill reaction, accumulating to unphysiological levels[23], but in normal photosynthesis they are feeding the transference of $H^+ + e^-$ from TPNH to the chemosynthetic processes producing carbohydrates from $CO_2 + H_2O$

Introduction of water in the electron cycle means an extension of the electron transference to an outer circuit (the water bridge) The reducing moiety is here acting as the cathode and the oxidizing moiety as the anode The electrons expelled from the excited chlorophyll are thus passing over the water bridge back again to the chlorophyll molecule (reaction 4)

The observed oxidation of the cytochromes on addition of TPN indicates a retardation or partial reversal of reaction 2 It may be expected that this initial retardation will decline slowly because of a simultaneous stimulation of reaction 1 The experiments show that the initial oxidation of the cytochromes soon disappears and even may turn over to reduction (Fig 4)

On addition of TPNH, reaction 2 is going from left to right. This initial response, which results in an increased reduction of the cytochromes, soon declines after the speed of photophosphorylation has adjusted itself to the increased supply of electrons (Fig 4)

The mere fact that the sudden start of the electronic cycle at turning on the light does not affect uniformly all links in the chain proves the existence of a spatial organization and of factors or zones of specific conductivity interspersed between the enzymes Similar to the respiratory enzymes, the corresponding enzymes in chloroplasts are very probably organized in sub-micro-multimolecular groups[3] (layers, rod-like or helical formations, etc) which are reacting at specific points ('reaction centres'[7]) or surfaces A number of observations furthermore indicate the existence of intermediate factors[19], lipids or quinones, which are acting as electrical machines transforming the motive power of electrons into chemical energy Most important are those machines which produce ATP The intermediate factors are largely responsible for the internal conductivity of the system and the observed specific response of the various cytochromes may be interpreted as a reflexion of local changes in their conductivity

The three points of phosphorylation are probably individually sensitive to variations of substrate concentrations, a circumstance that might explain negative results regarding the 'exchange reaction' between ADP and ATP [20] It is important to distinguish between the initial response, which, according to the present article, mirrors the points of substrate sensitivity, and the adaptation of the total cycle to the changed conditions, which, as shown here, may be completed in less than 1 min Conventional biochemical methods are insufficient for studying the initial effects In yeast the mechanisms of oxidative phosphorylation were shown to be regulating the internal conductivity and hence the speed of electron transference from reduced substrates to oxygen From the present results it may be inferred that in chloroplasts, too, the internal conductivity varies with the intensity of the ATP formation

It has been shown that the external circuit (the water bridge in chloroplasts which are consuming both water and ATP during the chemosynthesis of carbohydrates) is sensitive to the presence of salts, in particular chloride, whereas salts are reported as not affecting the internal circuit[11] This points to the existence of alternate pathways between TPN and the cytochromes as shown in Fig 6 It appears from this scheme that the internal stream of electrons is automatically switched over to the water bridge the moment $H^+ + e^-$ are consumed for reduction of carbon dioxide

In 1954 I advanced the idea that anions may, in chloroplasts, play a similar part as carriers of electrons as they are doing in the respiratory chain[5] What is going on in the water bridge may be characterized as a hidden electrolysis of water (only oxygen is evolved, $H^+ + e^-$ is hidden in reduced products) Salts are promoting *in vitro* the electric conductivity and stimulating the electrolysis, and the same may be true regarding chloroplasts The fact that chloride serves preferably as an electron carrier in photosynthesis may depend on the ability of chloride ions to be adsorbed firmly to the structure[21] Also, the stimulating influence of salts on respiration may be specific, owing to hydration, specific mobilities, etc , of anions and cations, but the specificity is generally less pronounced than in the case of photosynthesis

These investigations have been supported by the Swedish Research Councils for Natural Science and Agriculture and by a grant (*RG*7737) from the U S Public Health Service

RADIOPHYSICS

Riometer Observations during a Solar Eclipse

During the solar eclipse of October 2, 1959, recordings of cosmic noise (extra-terrestrial radio waves) intensities were made with riometers at the Sagamore Hill Radio Observatory of the Air Force Cambridge Research Laboratories in Hamilton, Massachusetts. The observing site is 243 ft. above sea-level at 70° 48′ 56″ west longitude and 42° 37′ 51″ north latitude and was directly in the path of totality.

The riometer consists of a servo-controlled, self-balancing receiving system which compares the incoming cosmic noise signals with the noise output of a diode vacuum tube. Any change in the value of the input signal to the receiver is detected by an internal balancing system, and a corresponding change in the filament temperature of the noise diode is effected. The actual recorded trace is driven by the filament current of the servo noise diode and represents the power-level of the incoming cosmic noise at the antenna. Variations in the recorded signal strength from the normal day curve are due to fluctuations in the charged particle population of the atmosphere, in particular changes in the electron density of the ionosphere. The attenuation curve of a 27·5 Mc./sec. radio wave passing through the atmosphere is shown in Fig. 1 and was derived from electron density profiles and electron-neutral particle collision cross-sections (personal communications from T. J. Keneschea and G. Gassman).

On the day of the eclipse, the Sun rose approximately 10 min. before second contact. Totality began at 5 hr. 50 min. 1 sec. and continued until 5 hr. 51 min. 32 sec. E.S.T. The solar eclipse occurred at an elevation of about 1° above the horizon and was of magnitude 1·02. The Fort Belvoir and planetary *K* indices were 5 during the observing period.

Two riometers were used in the measurements. One was tuned to a frequency of 30·25 Mc./sec., with its antenna oriented toward the zenith. The other was tuned to 27·5 Mc./sec., and its antenna was pointed toward the eclipse. The antennæ were three-element Yagis with lobe dimensions of approximately 110° horizontally by 60° vertically. The 27·5 Mc./sec. riometer antenna was mounted a half-wave-length above the ground with its axis of maximum sensitivity about 30° above the horizontal. The azimuth position of this beam was 95° E., the azimuth angle at which the eclipse would take place. The beam-width of the 27·5 Mc./sec. antenna was sufficiently large to enable signals to be well received before and just after totality. Since the antenna was stationary and did not track the Sun, incoming signals were received in different parts of the antenna reception lobe as time progressed. The recorded fluctuations in signal strength, therefore, indicate only relative changes in absorption. Because of the large antenna beam-width, however, the 27·5 Mc./sec. record provided an excellent indication of the variation of atmospheric absorption as the eclipse progressed.

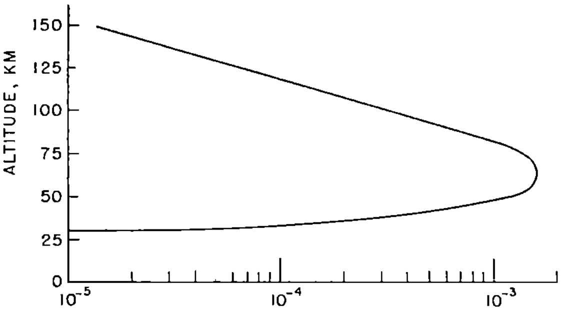

Fig. 1. Attenuation curve of a 27·5 Mc./sec. radio wave passing through the atmosphere

Fig. 2 shows the records of both the zenith and the eclipse riometers. The zenith riometer (30·25 Mc./sec.) shows no deviations from the normal quiet-day curve which was obtained from the records of the control days. The eclipse riometer record (27·5 Mc./sec.) shows slight absorption occurring before sunrise and an increase in cosmic noise of about 2 db. nearly coincident with optical totality. The pre-sunrise absorption may be due to the presence of auroral ionization observed in the backscatter records[1] of the Plum Island Observatory. It is of particular interest that peak cosmic noise intensity, corresponding to minimum electron density, is observed to follow optical totality by less than 30 sec.

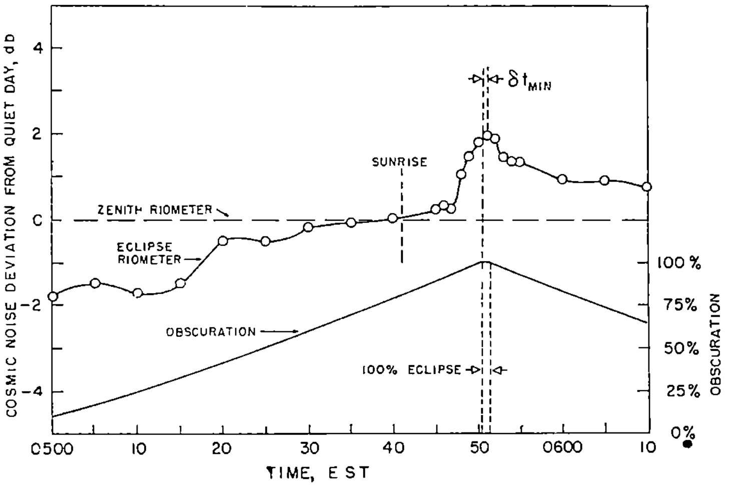

Fig. 2. Variation of cosmic noise from normal quiet day curve on October 2, 1959, during a solar eclipse. Percentage of obscuration also shown

As can be seen from Fig. 1, maximum attenuation for signals received by the eclipse riometer occurs at approximately 70 km., the *D* region. Because of the low angle at which the eclipse occurred, the path-length of the 27·5 Mc./sec. cosmic noise through the *D* region is about 200 km. Therefore, an average change of attenuation of 0·01 db./km. will explain the over-all change in attenuation of cosmic noise of

2 db At the zenith, the path-length is considerably less than the path-length in the direction of the eclipse Therefore, the small change in attenuation observed in the eclipse riometer would not result in a noticeable change of cosmic noise intensity measured in the zenith

Theoretical investigations of the E and F_1 regions during a solar eclipse have been made[2,3] Expressions involving the delay in time between optical totality and the minimum electron density have been derived Measured times of delay for the F_1 region during total eclipses are approximately 5 min , for the E region, 3 min[4] From my measurement, the delay time, $\delta_{\min}$, is determined to be about 30 sec for the D region Such a value is consistent with theory

This work has been sponsored by a National Science Foundation grant to the Arctic Institute of North America It was carried out at the Ionospheric Physics Laboratory, United States Air Force Cambridge Research Laboratories, Massachusetts I thank H Strick, of the Radio Astronomy Branch, for operation of the Zenith riometer and analysis of the zenith observations

GEOPHYSICS

World-wide Distribution of Diurnal Variation of the Neutron Intensity of Cosmic Rays

IT is important to glean information on ways in which cosmic rays are influenced in interplanetary space If it were possible to find world-wide distributions of cosmic rays and their variations with time, one might be able to obtain information on modulation of cosmic rays by magnetic clouds in interplanetary space As it is impossible, however, to normalize the cosmic-ray intensities at every station in the world at present, I investigated the world-wide distributions of local times of maximum intensity in the diurnal variations and their variations with time during the period of the International Geophysical Year, and the following results were obtained

Data of the thirty-nine stations in the world were used during the period July–December 1957, forty-five stations during January–June 1958, and forty-five stations during July–December 1958 These stations were classified into two groups, one is the mountain altitude group ($\geqslant$ 2,000 m above sea-level), the other the sea-level group ($<$ 2,000 m above sea-level)

T_m, the local time of the maximum intensity in the diurnal variation, was derived as follows

(1) The bi-hourly readings, represented by the procedure of Wada[1], were averaged over a period of one month, excluding all data of the imperfect days, and only the months having more than ten perfect days were used The harmonic analyses were carried out on these monthly mean diurnal variations, and the average value of T_m of each month was derived from the vector sum of the first and second harmonics

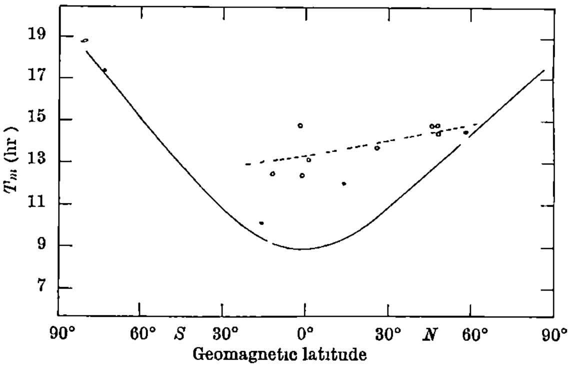

Fig 1. Relation between T_m and the geomagnetic latitude on the average, during the period July–December 1957 Full line and ●, sea-level group, dotted line and ○, mountain altitude group

(2) The average values of T_m during the period of each half-year were derived from the averaged values of the vector sum during six months of each period

Variations of T_m with the geomagnetic latitudes during the period of July–December, 1957, are shown in Fig. 1 It seems that there is a latitude effect in T_m, which has the minimum value around the geomagnetic equator Also the minimum values of T_m and the differences of T_m ($\Delta T_{m,\ 80°-0°}$) between 80° and 0° (geomagnetic latitude) of the latitude-effect curves belonging to the sea-level group have both clear correlations with the sunspot numbers determined by the Zurich Astronomical Observatory during each month It appears that minimum T_m advances and $\Delta T_{m,80°-0°}$ increases as the solar activity becomes intense Since many points deviate from the curve in Fig 1, lines of equal T_m were drawn in the world map in order to find reasons for this From the lines of equal T_m in the world map (Mercator's projection), it is seen that world-wide distributions have special tendencies there is a minimum value of T_m in the region from the Pacific Ocean to South Africa passing through South America, there are longitudinal effects, and the distributions tend to move every month, as shown in Fig 2

If it is possible to define broadly the minimum point between the northern hemisphere and the southern hemisphere as producing the equator, it is then possible to consider the minimum point of T_m as a kind of cosmic-ray equator, instead of the minimum point of the intensity, and this may be important, since one cannot normalize the intensity of stations Thus it may be plausible to suggest that the cosmic-ray equator is moving with time

From the results mentioned before, it may be suggested that the cosmic-ray intensity is controlled by three factors the first is due to the inner terrestrial magnetic dipole, the second due to the modulation by magnetic clouds in interplanetary space, and the third due to deformation of the lines of force of the geomagnetic field by contact with magnetic clouds

It may be suggested that, from the first factor, there exists the latitude effect on the average, from the second, minimum T_m advances and $\Delta T_{m,\ 80°-0°}$ becomes large as the solar activity becomes intense, and from the third are derived variations with time of the world-wide distribution of T_m and the cosmic-ray equator

It was pointed out by Simpson *et al* [2] and others[3] that a difference between the geomagnetic equator and

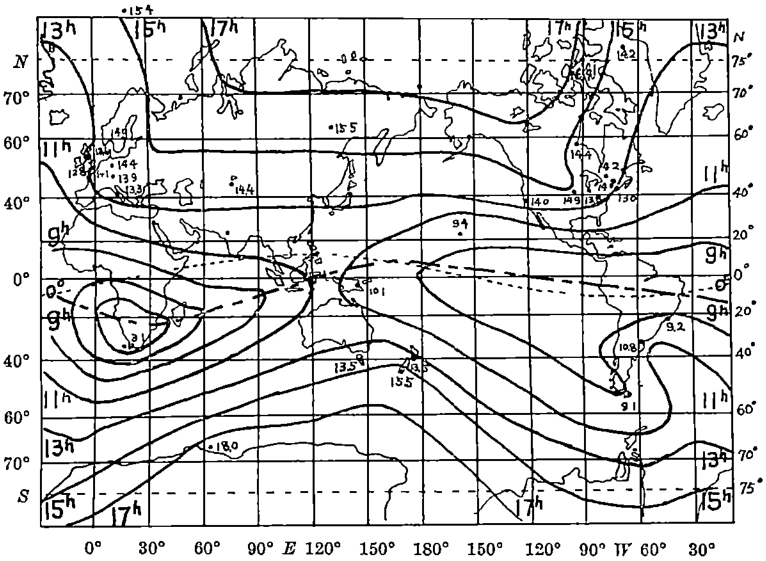

Fig 2 The average world-wide distribution of T_m during the period July–December 1957 The heavy chained line shows the cosmic-ray equator determined by T_m The fine dotted line shows the geomagnetic equator Numbers at stations show T_m (units/hr) belonging to them

the cosmic-ray equator exists, but the reason for this has not been made clear until now The cosmic-ray equator, that was established by them, was produced from data obtained at different times If it is true that the location of the cosmic-ray equator may also vary with time because the cosmic ray is modulated in interplanetary space, it may be permissible to determine the location of the cosmic-ray equator without consideration of the variation with time

I thank the directors and staffs of all the stations from which data were obtained for this work These data were obtained through *WDC*–C2 by Dr Y Miyazaki *et al* , whom I wish to thank too Also my thanks are due to Prof Y Kato for his suggestions and continuous encouragement, to Prof Y Sekido, the chief director of the Primary Cosmic-Ray Co-operative Research Group in Japan, and members of this group for their help

Effect of a Lake on Distribution of Permafrost in the Mackenzie River Delta

THE thawing effect of water in contact with permafrost is of considerable importance to engineers engaged on construction work that may involve flooding areas of perennially frozen ground There is little information at present available, however, to indicate the magnitude of the effect which might be expected An investigation of the present level of permafrost under natural bodies of water in the north, such as lakes and streams, is one means of improving our knowledge of this effect and of providing some guidance to engineers During April 1961 a drilling programme was carried out by the Division of Building Research of the Canadian National Research Council to determine the distribution of permafrost under a lake in the Mackenzie River Delta (68° 18′ N , 133° 50′ W) at the new town-site of Inuvik, Northwest Territories, near the arctic coast

A small lake was selected for investigation following a preliminary study of aerial photographs and a field reconnaissance, in 1960, of a portion of the delta within a 10-mile radius of Inuvik This lake, located about 5 miles south-west of Inuvik, is approximately circular, having a diameter of about 900 ft Like all delta lakes it is shallow At the time of investigation the ice cover was about 2 25 ft thick and the average depth of water was 1 5–2 ft The snow cover was on the average 12–15 in The colour of the lake water was light brown and a very strong odour of hydrogen sulphide was noticed when the bottom sediments were disturbed The dense forest vegetation around the lake is typical of the climax developed in the lower valley and delta of the Mackenzie River The dominant species is white spruce, the largest trees growing to a height of 50 ft Also present are black spruce, willow and alder with scattered stands of tamarack The apparently continuous moss cover is about 1 in thick

A diamond drill-bit was used to drill and sample the various materials encountered The operation was greatly complicated by the presence of permafrost and the subnormal air temperatures which occurred during April Water, obtained from the lake at a temperature of 33°–35° F , was used as a circulating medium except for an unsuccessful attempt to use arctic grade fuel oil in one hole When using water, drilling techniques had to be slightly modified and precautions taken to prevent freezing of equipment in the hole Hot water was circulated periodically to keep the hole free of ice

During the course of the investigation, four holes were drilled at the locations and to the depths noted No 1, centre of lake—to 240 ft , No 2, 33 ft west of lake—to 115 ft , No 3, 132 ft west of lake—to 196 ft , No 4, 550 ft west of lake—to 260 ft

To measure ground temperatures, two thermocouple cables were installed to depths of 100 and 200 ft in holes Nos 3 and 4 respectively

Good undisturbed cores were obtained which indicated the following soil profile 0–100 ft , thinly stratified sandy silt with layers of decomposed organic material throughout, 100–180 ft , fine to medium sand with thin layers of organic material in the upper 40 ft , 180–240 ft , very dense, clay-sized soil (free of stones except for last few feet)

Representative samples were taken for identification and classification testing of the soils, moisture (ice) content, pollen analysis, carbon-14 age determinations and petroleum pigment analysis Bedrock (a dolomitic limestone) was encountered in hole No 3 at a depth of 230 ft and in hole No 4 at a depth of 260 ft

Although testing of samples has not been completed nor the information fully analysed, a number of observations can be made. No frozen ground was encountered throughout the depth of the hole under the lake (No. 1), but did occur for the full depth of each of the three other holes. Initial ground temperature measurements suggest that the permafrost is about 250 ft. thick at the location 130 ft. from the lake and about 300 ft. thick at a distance of 550 ft. from the lake.

Probings showed that the permafrost table extended out from shore under the lake and sloped down steeply. 10 ft. from the shore the permafrost table occurred 15·5 ft. below the ice surface; 12 ft. from the shore at a depth of 19·7 ft.; at 15 ft. it was more than 22 ft. below the ice. Although the soils encountered in the three holes adjacent to the lake (Nos. 2, 3 and 4) were solidly frozen, little ice was observed in the soils below the 20-ft. depth. Although flooding of the lake and surrounding area probably does not occur each year, it appears that it may occur at intervals of a few years. Marks on tree trunks indicate an extreme high-water mark about 5 ft. above the present ground surface at the lake, that is, about 20 ft. above the winter ice-level of a nearby delta channel.

METEOROLOGY

Size Distribution of Raindrops

A. C. BEST[1] has found an empirical formula for the size distribution of raindrops. If $F(x)$ is the fraction of liquid water in the air comprised by drops of diameter less than x

$$F = 1 - \exp[-(x/a)^n]$$

where a and n are constants for any particular rainfall. Contrary to the general supposition that the above formula applies to the average size distribution of a number of samples of rain, I have found that the formula holds for individual samples in 90 out of 104 cases of general monsoon rains and in 134 out of 169 cases of thunderstorm rains recorded at Poona, provided the samples are sufficiently representative. The formula fails where the liquid water distribution is multimodal (generally bimodal) or where the distribution curve has a long tail with a sharp maximum either at the beginning or at the end.

The parameters a and n are found to be independent for general rains but are connected by the average relation $an = 7\cdot1$ mm. for thunderstorm rains. There is also a correlation between the intensity of precipitation I (mm./hr.) and the parameter n. For general rains the average relation found is

$$I = 6\cdot9 \exp[-0\cdot14(n - 5\cdot5)^2]$$

and that for thunderstorm rains is $I = 975 \exp(-n)$.

PHYSICS

Stark Broadening of the Spectrum Line 4603 Å. of Lithium

THE Stark broadening of spectrum lines, in particular the lines of hydrogen, has been of interest to astrophysicists for many years. Recent advances in plasma physics on a laboratory scale have emphasized the need for a better understanding of the relationship between the number density of charged particles in a plasma and the profiles of the spectrum lines from the plasma. The broadened hydrogen lines from a water-stabilized carbon arc have been studied carefully by workers at Kiel[1-3], and the latest refinements of the theory of line broadening describe the profile of Hβ quite accurately[4].

The shock tube is a very useful device for studying spectrum lines from plasmas, since the degree of ionization and the temperature behind the shock wave can be varied over a wide range and calculated from measurements of the shock speed. The shock tube used for the present work has a low-pressure section 18 ft. 7 in. long, and a high-pressure section 3 ft. long. Argon is used as the test gas in the low-pressure channel, and hydrogen as the driver gas in the high-pressure section. Diaphragms of aluminium or 'Mylar' are used, depending on the bursting pressure desired. Spectra are obtained with a Raman glass spectrograph. Spectra can be resolved in time by sweeping the spectrograph slit with a rotating disk having a number of radial slots.

Lithium was chosen for initial Stark broadening studies, since this shows a large Stark effect for some of its lines, particularly the line at 4603 Å. Hydrogen and helium both have large Stark shifts, but were not used since their presence in quantities large enough to give easily photographed spectrum lines would reduce the shock strength quite markedly. The lithium was introduced into the shock tube in the form of lithium chloride which was supported on a short rod mounted on the closed end of the tube. A time-resolved spectrum showed that the lithium was excited behind the shock wave reflected from the closed end of the tube. A time-integrated spectrum is shown in Fig. 1. The argon lines are broader than those emitted from an argon discharge lamp and they are also shifted a little to the red. Hβ appears very faintly; this is excited near the contact surface between the hydrogen driver and the argon. The lithium line at 4603 Å. is very broad. The blackening profile of this line is shown in Fig. 2.

In the analysis of this line it has been assumed that the line is broadened solely by the statistical micro-fields due to ions. The broadening of the lithium line at 4603 Å. has been treated approximately by Holstmark using some experimental results obtained by Stark on sparks through lithium vapour[5]. Since then, more accurate Stark results have become available for lithium mainly through the experimental work of Poirot and these results have been used for the present analysis[6].

The lithium line at 4603 Å. arises from a $2p$–$4d$ transition. Under the action of a uniform electric field this line is displaced to longer wave-lengths and two other lines appear, one due to a $2p$–$4p$ transition and the other to a $2p$–$4f$ transition. The $2p$–$4p$ transition gives a weak line at 4636 Å. for vanishingly weak electric fields, shifting to longer wave-lengths at increasing field strengths.

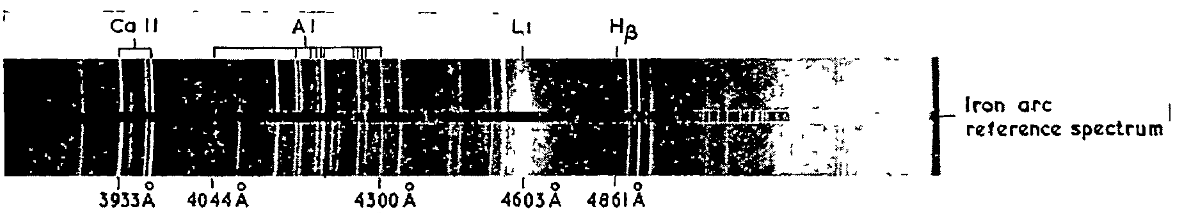

Fig. 1. Lithium excited in the shock tube, showing Stark-broadened line at 4603 Å. The Stark-broadened hydrogen line Hβ is just visible also

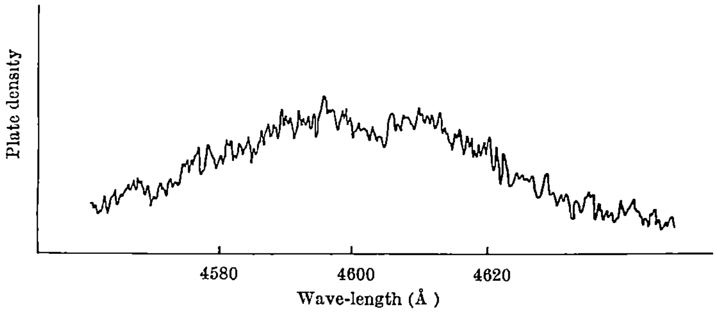

Fig. 2. Density profile of Stark-broadened line of lithium at 4603 Å

The $2p$–$4f$ transition gives a line at 4602 Å for vanishingly weak fields, shifting to shorter wave-lengths at increasing field strengths. Data on the intensities of these Stark components are not available and therefore the full-line contour cannot be worked out as it has been done for the hydrogen lines by Schmaljohann, who applied Holtsmark's statistical theory to the known Stark data for hydrogen[7]. In order to overcome this difficulty it is assumed that the long wave-length part of the contour, having a maximum at 4611 Å, is due solely to the $2p$–$4d$ transition, and the weaker $2p$–$4p$ transition, which is much farther into the red, is neglected. This part of the line contour cannot be encroached on by the line due to the $2p$–$4f$ transition, since that cannot affect any part of the line at wave-lengths greater than 4602 Å. Poirot gives only rough estimates of the intensities of the components, but from these estimates it appears that the line due to $2p$–$4d$ transition does not vary in intensity over the field strengths he used, which did not exceed 95 kV. per cm.

Poirot's results show that the Stark displacement varies very nearly as the square of the electric field strength. For the quadratic Stark effect, the statistical theory of line broadening for a single line leads to a line profile given by (ref. 8, equation 3.14)

$$I = \frac{W(\beta)}{2\nu_0\beta} \qquad (1)$$

where

$$\beta = \left(\frac{\Delta\nu}{\Delta\nu_0}\right)^{1/2} \qquad (2)$$

where $\Delta\nu$ is Stark displacement in cm.$^{-1}$ due to a field F, $\Delta\nu_0$ is Stark displacement in cm.$^{-1}$ due to a field F_0 and W is a probability function that has been tabulated by Schmaljohann[7].

F_0 is related to the number density of ions, N, by

$$F_0 = 2.61\, eN^{2/3} \qquad (3)$$

where e is the electronic charge (4.80×10^{-10} E.S.U.).

From Schmaljohann's tabulated values of $W(\beta)$, it is readily found that the maximum of I occurs when $\beta = 1.1$. Substitution in (2) for β gives the position of the maximum as $1.21\ \Delta\nu_0$. From direct measurement of the blackening contour (Fig. 2), this is 38 cm.$^{-1}$, which gives $\Delta\nu = 31.4$ cm.$^{-1}$. From an extrapolation of Poirot's results this corresponds to $F_0 = 122$ kV./cm.

Equation (3) then gives

$$N = 1.85 \times 10^{17} \text{ per c.c.}$$

In the actual experiment the shock wave Mach number was 9.2, and the initial pressure of the argon 5 mm. mercury. By calculation this gives a temperature of 11,500° K. and ion density of 1.6×10^{17} per c.c. behind the shock wave reflected from the end of the tube. There are two effects which would lead to a higher observed ion density than that computed behind the reflected shock wave: (1) the reflected shock wave undergoes a second reflexion at the contact surface before the radiation is finally quenched by the spreading contact surface. This second reflexion is shown by a time-resolved spectrum, and has the effect of further heating and compressing the gas, thus raising the number density of electrons and ions. Computations have not been carried out for this second reflexion. (2) The lithium itself almost certainly provides a large number of electrons and ions since this has a much lower ionization potential (5.39 eV.) than argon (15.75 eV.).

This work is proceeding further in order to investigate the effect of varying the number density of ions and electrons. The most recent work on hydrogen line broadening also shows the need to take into account the effect of electrons on the broadening, which has been neglected in this treatment[8].

This work is published by permission of the Director of the Laboratory. I acknowledge with thanks the assistance of Mr. J. Townsend in the experimental work.

Polarized Thermal Emission from Narrow Tungsten Filaments

FROM experimental work carried out by Fresnel many years ago and a theoretical investigation made by K Schwarzschild[1], it is well known that light transmitted through a narrow slit is more or less polarized Though conditions are rather different in the case of thermal emission from a narrow filament the idea has occurred to me that polarized emission may be obtained in this way in addition to inclined-surface-layer-effects described by Worthing[2] and others (Arago effect[3]) Through the courtesy of Dr G Siljeholm of the Lumalampan Aktiebolag in Stockholm I have been able to test recently some filaments no thicker than 4 8μ The experiments were carried out at the Swedish Solar Observatory in Anacapri, and a polarization as high as 28 per cent has been found in the red The plane of vibration (electric vector) is perpendicular to the direction of the filament Considering the fact that the 4 8μ filament had not been polished as in the case of Worthing's measurements, the high value obtained in the red (28 per cent instead of 19 per cent found by Worthing) gives some indication that a 'slot-aerial' effect might be present To some extent this view is supported by measurements of a 6 5μ filament showing already a smaller degree of polarization than a polished broad filament. Furthermore, when examining with a Savart polariscope the interference fringes appearing in highly magnified images, it has been found that the polarization appears to be nearly the same in the central part of the wire as at the limb Though the resolving power may have been insufficient for separating the regions clearly, it seems hard to explain the observation by means of the Arago effect alone

By using different colour screens I have been able to establish an increase of polarization with wave-length. The determinations are presented in Table 1 The effective wave-length λ transmitted through the filters has been estimated with a spectroscope The degree of polarization was measured with a Cornu polarimeter, except in the case of infra-red radiation for which photographic observations were made Special precautions were taken to avoid polarization effects due to reflexion in the glass tube, etc

In Table 1 the quantity $\frac{d}{\lambda}$ is given as well as $P\frac{d}{\lambda}$, d being the thickness of the wire As is evident from the last column $P\frac{d}{\lambda}$ is remarkably constant and approximates to 2

In Fig 1 the degree of polarization is plotted against $\frac{d}{\lambda}$ using dots for $d = 6\ 5\mu$ and crosses for $d = 4\ 8\mu$ The dots follow closely a straight line All values follow closely the hyperbola $P\frac{d}{\lambda} = 2$ presented as a dashed curve When using instead $1/\lambda$ as abscissa the crosses and the dots give different relationships This indicates again that an aerial effect may be present The probable behaviour close to $\frac{d}{\lambda} = 1$ has been indicated by the dotted curve by taking into account the phenomena produced by a narrow slit If the relation $P\frac{d}{\lambda} = 2$ is valid also for smaller values of $\frac{d}{\lambda}$ than those examined here, the highest polarization would be expected when the thickness of the filament is about twice the wave-length of light

Table 1

$d(\mu)$	$\lambda(\mu)$	$\frac{d}{\lambda}$	P	$P\frac{d}{\lambda}$
● 6 5	0 48	13 5	0 14 ± 0 02	1 9
	0 55	11 8	0 16 ± 0 01	1 9
	0 64	10 2	0 16 ± 0 02	1 6
	0 66	9 8	0 19 ± 0 02	1 9
	0 82	7 9	0 22 ± 0 02	1 7
4 8	0 48	10 0	0 22 ± 0 02	2 2
	0 66	7 2	0 28 ± 0 02	2 0

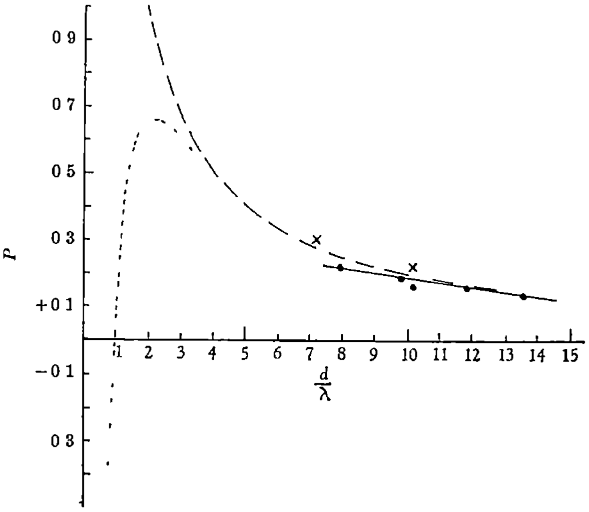

Fig 1

Preparations are being made for extending the measurements to narrower filaments It is planned to ascertain also whether narrow bolometer filaments may be used for the purpose of analysing polarization in the infra-red

CRYSTALLOGRAPHY

Crystallographic Data for Urea Calcium Nitrate and Urea Cadmium Nitrate

THE crystal structures of urea calcium nitrate and urea cadmium nitrate are being investigated as part of a survey of hydrogen bonding in urea inorganic salt complexes Preliminary work has shown that urea calcium nitrate and urea cadmium nitrate are isostructural and belong to the monoclinic system

By using small single crystals mounted on a Seifert diffractometer and copper K_α radiation, accurate values for the translations d_{001}, d_{100}, d_{101} and b were obtained The accurate estimates were made by plotting the values of these translations, determined from the $00l$, $h00$, $h0l$ (for $h = 1$) and $0k0$ reflexions, against the function[1] $\frac{1}{2}\left(\frac{\cos^2\theta}{\sin\theta} + \frac{\cos^2\theta}{\theta}\right)$ and extrapolating to zero

The monoclinic angle β was calculated by means of the equation

$$\beta = \text{arc cos}\ \frac{d^2_{101}(d^2_{100} + d^2_{001}) - (d_{100}d_{001})^2}{2d_{100}d_{001}d^2_{101}}$$

By using the calculated value of β and the observed values of d_{001} and d_{100}, the unit cell translations c and a were derived

The systematic absences were deduced from indexed Weissenberg photographs taken about the unit cell axes

The densities were determined by flotation of the crystals in toluene/bromoform mixtures

A summary of the crystallographic data for urea calcium nitrate and urea cadmium nitrate is given in Table 1

Table 1

	Urea calcium nitrate, $Ca(NO_3)_2 4(NH_2)_2 CO$	Urea cadmium nitrate, $Cd(NO_3)_2 4(NH_2)_2 CO$
a	7 683 ± 0 002 Å	7 607 ± 0 002 Å
b	12 665 ± 0 002 Å	12 772 ± 0 002 Å
c	9 245 ± 0 002 Å	9 040 ± 0 002 Å
β	113° 32′ ± 2′	114° 4′ ± 2′
No of molecules per unit cell	2	2
Measured density	1 634 gm cm $^{-3}$	1 968 gm cm $^{-3}$
Calculated density	1 628 gm cm $^{-3}$	1 973 gm cm $^{-3}$
Linear absorption coefficient for copper K_α radiation	41 9 cm $^{-1}$	123 0 cm $^{-1}$
Systematic absences		
$h0l$	$h = 2n + 1$	$h = 2n + 1$
$0k0$	$k = 2n + 1$	$k = 2n + 1$
Space group (uniquely determined)	$P2_1/a$	$P2_1/a$
$a/2 - c \cos \beta$	0 150	0 118

All the crystals of urea cadmium nitrate that were examined were found to be twinned, with (010) forming the composition plane. Examination of the (010) Weissenberg photographs of urea cadmium nitrate showed that twinning had occurred as a result of a two-fold rotation about the a axis Since the relation $c \cos \beta = \frac{a}{2}$ holds fairly closely for urea cadmium nitrate, this is an example of twinning according to the Carlsbad Law[2]

No evidence of twinning has been observed in the isostructural urea calcium nitrate complex, for which the value of $\frac{a}{2} - c \cos \beta$ is equal to 0 150 as compared with the value of 0 118 for urea cadmium nitrate.

CHEMISTRY

A Transition in the Dielectric Properties of Solid Secondary Alcohols

Since the discovery of the large dielectric absorption in aliphatic secondary alcohols[1], there have been several papers[2–4] published on this subject The only definite conclusion about the mechanism is that the presence of some lattice defect or arrangement of defects is required for this large absorption[3,4]

In the belief that further progress can be made only from measurements on single crystals grown from pure material, attempts have been made to grow single crystals from the melt The solid grown to date has been below the standard it is hoped to obtain eventually Nevertheless, measurements made on the oriented polycrystalline material obtained has revealed a sharp transition in the dielectric properties of certain alcohols at a temperature about − 4° C The transition was not apparent in samples pressed from powders, although a suggestion of its presence was noted in samples annealed for long periods

The solid was that used by Meakins and Sack[1], zone-refined and grown from the melt by a Bridgman method The secondary alcohol was contained in a glass tube which was evacuated to a pressure of 10^{-5} mm mercury. The tube was lowered through a sharp and highly stable temperature gradient at 0 5 in a day After removal from the tube, plane parallel sections for measurement were cut in three perpendicular directions, using a wet string saw One of these directions was perpendicular to the growth axis In some experiments 'Aquadag' electrodes were painted on the samples

In the case of 9-heptadecanol ($C_8H_{17}CHOH\,C_8H_{17}$), the absorption at room temperature is comparable in all three directions However, the change in dielectric absorption at the transition is three times greater in the two directions for which the measuring field is perpendicular to the growth axis than when the field is in the direction of the growth axis In Fig 1 the dielectric absorption for one of these samples is

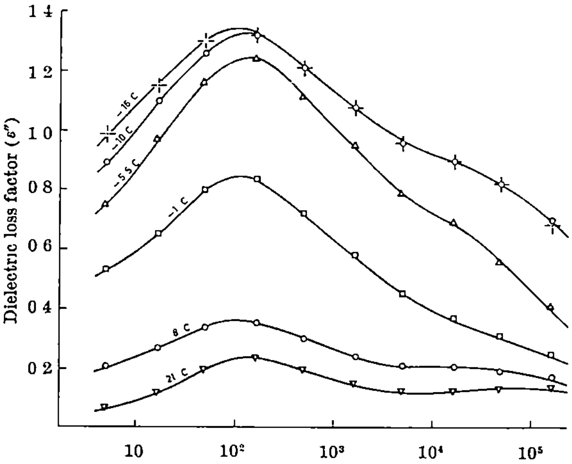

Fig 1 Dielectric-loss factor as a function of frequency for the symmetrical secondary alcohol 9-heptadecanol

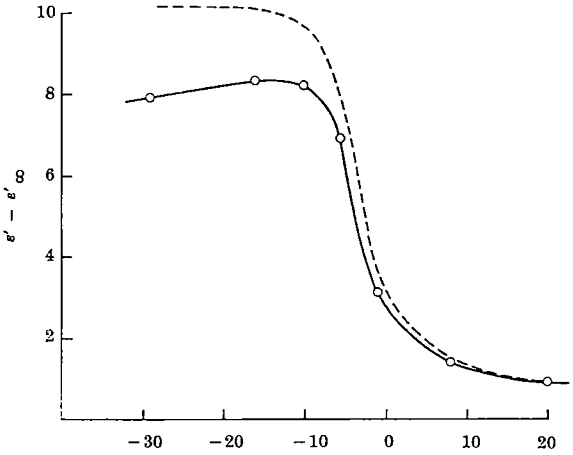

Fig 2 $\varepsilon' - \varepsilon'_\infty$ for 9-heptadecanol as a function of temperature The full line refers to ε' measured at 4 8 c /s , the dotted line to an estimated ε'_0, that is, the permittivity below the absorption region plotted as a function of frequency at several temperatures In Fig 2 the relative permittivity at a frequency of 4 8 c /s is plotted as a function of temperature, the dotted curve is an estimated ε'_0 obtained by extrapolating the absorption curves to frequencies below 4 8 c /s and measuring the area under the extrapolated portion It can be seen that the dispersion ($\varepsilon'_0 - \varepsilon'_\infty$) increases by a factor of 10(0 95–10) in passing through the transition

A similar transition at approximately the same temperature has been observed in 8-pentadecanol ($C_7H_{15}CHOH\ C_7H_{15}$), and evidence has been obtained of a less-sharp transition in 10-nonadecanol ($C_9H_{19}CHOH\ C_9H_{19}$) The best sample obtained of the latter material was considerably more polycrystalline than those of the other compounds

A direct-current voltage of 30 kV /cm was applied to the samples at temperatures both above and below the transition, the permittivity was linear up to this voltage

Further purification and growth of better crystals of these compounds are being attempted

We wish to acknowledge the contributions of Mr J S Cook and Mr K G Weir to the crystal-growing apparatus

1,2-Benzanthracene Derivatives in a Kuwait Mineral Oil

THE isolation of a number of polymethylanthracenes from fractions of a Kuwait crude oil has been reported by one of us[1] The hydrocarbons were obtained by treatment of acetone extracts of the oil with maleic anhydride and chromatography of the material recovered from the acidic adducts by distillation from sodium hydroxide We have now applied the same procedure to higher-boiling fractions of acetone and furfural extracts of the Kuwait oil (corrected boiling points in the range 390–440° C) and have obtained crystalline fractions consisting essentially of alkyl derivatives of 1,2-benzanthracene This is evident from their ultra-violet absorption spectra, which closely resemble those of typical alkylbenzanthracenes[2] Vapour-phase chromatography of some of the fractions indicates, however, that they are mixtures containing varying proportions of benzanthracene and other components with retention times similar to those of mono- and dimethylbenzanthracenes 1,2-Benzanthracene itself was isolated from several fractions by further chromatography on alumina as colourless plates, m p 154–156° undepressed, when mixed with an authentic specimen, m p 158–159° The ultra-violet spectrum of the isolated material (λ_{max} 228, 256, 267, 277, 287, 299, 314, 327, 342, 358, 374, 384 mμ, log ε, 4 54, 4 51, 4 64, 4 89, 4 98, 3 95, 3 70, 3 80, 3 85, 3 69, 2 69, 2 86), and the infra-red spectrum[3], were identical with those of 1,2-benzanthracene, and vapour-phase chromatography gave one peak with retention time similar to that of benzanthracene under the same conditions The 2,4,7-trinitrofluorenone addition complex formed red needles, m p 217–221°, not depressed when mixed with an authentic specimen, m p 220–223° [4], and the identification was confirmed by preparation of the *s*-trinitrobenzene complex, orange needles, m p 161–163°, and comparison of this with an authentic specimen, m p 162–163° (found C, 65 3, H, 3 6, $C_{24}H_{15}N_3O_6$ requires C, 65 3, H, 3 4 per cent)

A second product, m p 192–194 5°, obtained in very small amount after purification by chromatography and sublimation, did not depress the melting point of 4′-methyl-1,2-benzanthracene (m p 199–200°)[5], and the ultra-violet spectrum (λ_{max} 226, 228–9, 256, 271 5, 281 5, 292 5, 302, 316, 328 5, 344, 361, 387 mμ, log ε, 4 55, 4 55, 4 57, 4 65, 4 78 4 79, 4 02, 3 77, 3 80, 3 81, 3 66, 2 94) was identical with that of this hydrocarbon The infra-red spectra were also identical in the region 650–900 cm $^{-1}$ (there was insufficient material to obtain a well-defined spectrum over the remainder of the normal range)[3] The 2,4 7-trinitrofluorenone complex formed brown needles, m p 223–227°, and when mixed with the derivative of 4′-methyl-1,2-benzanthracene (m p 233–235°)[6] the melting point was 224–230° The *s*-trinitrobenzene complex gave red needles, m p 158–160°, mixed with the derivative of the 4′-methyl compound m p 165 5–168°, the melting point was 160–168° Because of the very small amounts of material available it was not possible to obtain the derivatives completely pure, but the results reported, taken as a whole, may be considered to justify the identification of the substance from the oil as 4′-methyl-1,2-benzanthracene

The presence of derivatives of 1,2-benzanthracene in fractions of the Kuwait oil is of interest with regard to the carcinogenic activity of the oil[7] We have not as yet been able to obtain an accurate estimate of the amount of benzanthracenes present, but spectroscopic evidence indicates that, in one fraction of corrected boiling point 390–405°, it is certainly less than 0 25 per cent of the acetone extract, disregarding possible losses during decomposition of the maleic anhydride adducts 1,2-Benzanthracene itself is generally considered to be non-carcinogenic or only very weakly so when tested by skin painting on animals[8,9], but it has been reported to be moderately active by subcutaneous injection in mice[10] 4′-Methyl-1,2-benzanthracene has been shown in one series of tests to be a very weakly active carcinogen towards mouse skin[11]

Several other crystalline substances have been obtained by chromatography of those fractions of the oil which did not react with maleic anhydride One of these, obtained as colourless needles, m p 195–199°, was shown to be triphenylene by mixed melting point with an authentic specimen, m p 202–204° [12], by ultra-violet absorption measurements (λ_{max} 249, 257 5, 273, 284, 320, 328, 335 mμ, log ε, 4 93, 5 15, 4 37, 4 32, 2 87, 2 70, 2 72)[13] and by elementary analysis (found C, 94 6, H, 5 3, calc, for $C_{16}H_{12}$ C, 94 7, H, 5 3 per cent) Another substance, m p 252–256°, was identified as chrysene (m p 256°)[14] by mixed melting point and ultra-violet absorption (λ_{max} 241, 258, 267, 294, 306 5, 320, 344, 352, 361 mμ, log ε, 4 62, 5 18, 5 36, 4 39, 4 44 4 43, 3 12, 2 84, 3 10) The infra-red spectrum was identical with that of chrysene, and on vapour-phase chromatography one peak was obtained with retention time similar to that of chrysene The *s*-trinitrobenzene complex formed yellow needles, m p 189°, not depressed when mixed with an authentic specimen, m p 191–193° (lit m p 192–194°)[4]

None of the hydrocarbons reported here has previously been isolated from an uncracked petroleum fraction Claims have been presented, based on spectroscopic evidence, for the occurrence of chrysene and of 1,2-benzanthracene in the aromatic fraction of a clarified oil[15], and of chrysene, triphenylene and 1,2-benzanthracene in a paraffin wax of unspecified origin[16]

We are indebted to Dr J. W Cook for his interest and encouragement, and to Prof F Morton, of the Manchester College of Science and Technology, for supplying us with the oil fractions used in the investigation

Partition Isotherms and Gas-Liquid Chromatography

The various well-known theories of gas-liquid chromatography all assume a linear 'partition' isotherm, that is, the concentration of a solute in the stationary liquid phase is a linear function of the concentration in the gas phase, also the theories are unanimous in predicting symmetrical elution peaks Asymmetrical peaks, when they occur, are variously ascribed to 'overloading' of the column, lack of attainment of equilibrium, adsorption on the solid support and at the gas-liquid interface, and finally, non-ideal solution behaviour[1] Non-ideality is taken to mean that the solutions show deviations from Raoult's law We wish to make two points, first, that partition isotherms are frequently markedly non-linear and, second, that non-ideal solution behaviour is not important in determining elution peak symmetry, but that isotherm shape is We base our arguments on the results of experiments which were aimed at the determination of partition isotherms by a static method

Using a modified McBain–Bakr balance we have measured the partition isotherms of a number of vapours in a variety of liquids commonly used as stationary phases in gas-liquid chromatography The method was as follows a small sample of 'Celite' coated with the liquid stationary phase was weighed into a small glass bucket and suspended from a silica spring (extension approximately 1 m per gm) and the system degassed to a vacuum of 10^{-4}–10^{-5} mm of mercury Small charges of the vapour were then admitted to the system and the uptake by the liquid determined by measuring the extension of the spring In this way we have investigated the solubility of the following vapours at a number of different temperatures cyclohexane, benzene, dichloromethane, chloroform and carbon tetrachloride in dinonyl phthalate and squalane, and additionally, benzene in benzyl diphenyl, diglycerol and silicone oil Similar measurements have been made by Everett and Ashworth[2] Some of the isotherms determined at 30° C are shown in Fig 1 With the exception of the system benzene–diglycerol, in which there was negligible uptake of benzene by the diglycerol, even at relatively high pressures, all the isotherms obtained were of the same general shape, that is, all were curved in a direction convex to the concentration axis This establishes our first point It is only fair to point out, however, that these isotherms approximate to linearity at low concentrations, hence, provided that only small samples are used in gas-liquid chromatography, symmetrical elution peaks should be obtained In passing, it is interesting to note that the isotherms curve in the opposite sense to that usually observed in adsorption at a solid surface

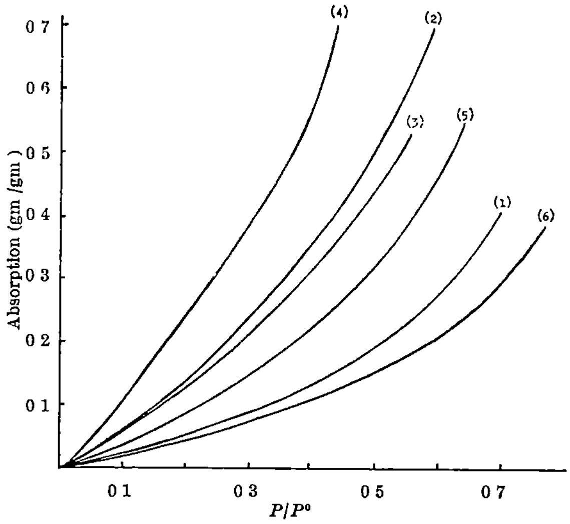

Fig 1 Isotherms at 30° C (1) Cyclohexane in dinonyl phthalate, (2) carbon tetrachloride in dinonyl phthalate, (3) dichloromethane in dinonyl phthalate, (4) chloroform in dinonyl phthalate, (5) cyclohexane in squalane, (6) dichloromethane in squalane

It has been shown theoretically by de Vault[3] and experimentally by Gregg and Stock[4] that systems giving rise to isotherms of the shape illustrated in Fig 1 will, if used in chromatography, tend to give elution peaks with diffuse front boundaries ('fronting') and sharp tails, and there is no doubt that such peaks are frequently observed in gas-liquid chromatography when rather large samples are used (as may be necessary when a comparatively insensitive detector is employed) Now Raoult's law defines an ideal solution as one which gives a straight line when the partial vapour pressure of a component is plotted against its mole fraction, x (In the systems under consideration only one of the components exerts an appreciable vapour pressure, that of the stationary

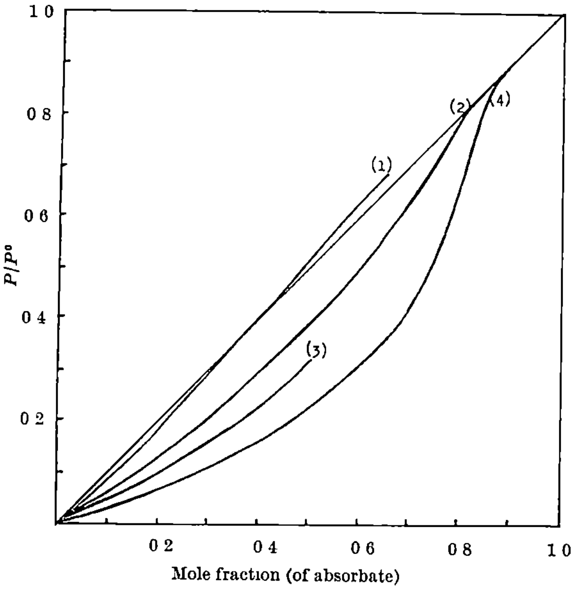

Fig 2 Deviation from Raoult's law at 30° C, all in dinonyl phthalate (1) Cyclohexane, (2) carbon tetrachloride, (3) dichloromethane, (4) chloroform

liquid can be neglected) If we now replot the isotherms involving dinonyl phthalate in Fig 2 using mole fractions instead of concentrations, we observe that three of the systems show negative deviations from Raoult's law and one shows both a positive and a negative deviation, in spite of the fact that the corresponding isotherms are all the same general shape. It can easily be ascertained that systems which obey Raoult's law or give positive deviations will still give curved isotherms of the type illustrated To obtain isotherms which are curved in the opposite sense, that is, are concave to the concentration axis, and which would therefore give rise to tailing, the most pronounced negative deviations from Raoult's law are necessary Such a system has never been observed by us. We are therefore of the opinion that 'fronting' is an inherent tendency in gas-liquid chromatography, but will not be marked, or even noticeable, when low concentrations of the solute are used Tailing is seldom, if ever, caused by deviations from ideality of the gas-liquid system, and is most probably due to the adsorption on the solid support, or perhaps at the gas-liquid interface

Finally, we would like to record that our results for the system showing both positive and negative deviations from Raoult's law, namely, cyclohexane–dinonyl phthalate, confirm the measurements and predictions of Everett and Ashworth[2] Very careful measurements were made to establish the deviation at low concentrations of cyclohexane, and the relevant data are given in Table 1 Further investigations have shown that this type of system is by no means uncommon in gas-liquid chromatography

A Cyclic Tetramer of Chloral

Treatment of chloral or its hydrate with concentrated sulphuric acid yields a number of polymeric materials which were identified by Chattaway and Kellett[1] and studied by Novak and Whalley[2] From the mixture obtained in this Laboratory by treating some 300–400 gm of chloral hydrate, about 2 gm (0 5 per cent) of a new polymeric compound was isolated as a white crystalline solid (m p 219–220° corr) It crystallized from absolute ethanol as short needles slightly less soluble in this solvent than chloralide or α-parachloral The compound is very soluble in acetone, pyridine and ether, moderately soluble in boiling ethanol, slightly soluble in carbon disulphide, carbon tetrachloride and cold ethanol and insoluble in water Boiling with an aqueous ethanol–20 per cent sodium hydroxide solution liberates chloroform and formic acid Further work gave the following results Analysis, calculated for $(CCl_3\text{–}CHO)_n$ C, 16 28, H, 0 68, Cl, 72 17 Found C, 16 43, H, 0 73, Cl, 71 78 Molecular weight (Rast), calculated for $(CCl_3\text{–}CHO)_4$, 589 5 Found 614, 616, 571 (average 600 3) Infra-red spectrum the compound was examined in 'Nujol' mull (0 025 mm) and in saturated (18° C) carbon tetrachloride and carbon disulphide solutions (1 mm), on a model 137 'Infracord' spectrophotometer (with sodium chloride prism) The bands observed are recorded in Table 1

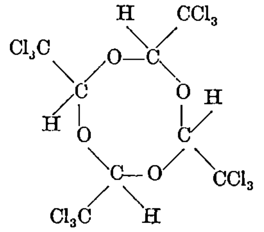
The results in Table 1 indicate (*a*) the absence of hydroxyl and carbonyl groups, (*b*) the presence of a cyclic ether linkage due to the series of bands in the 950–1,200 cm.$^{-1}$ (8.3–10.5μ) and 800–860 cm.$^{-1}$ (11.6–12.5μ) regions, and (c) a shift towards lower frequencies as compared with bands of other known cyclic ethers[3]. It is a well-established fact that there is a shift to lower frequencies whenever there is an increase in ring-size among cyclic ethers.

These results are consistent with the existence of a cyclic tetramer having the following formula:



A report on the structure of this compound, 2,4,6,8-tetrakis-(trichloromethyl)-1,3,5,7-tetroxocane, will be published elsewhere.

I am indebted to Dr. Oscar H. Saggese of this Department for his interpretation of the infra-red spectra.

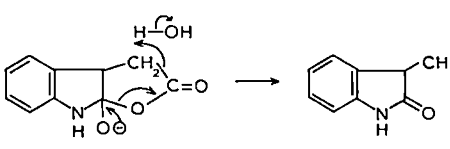
BIOCHEMISTRY

Oxidative Decarboxylation of Indole-3-acetic Acid by Mangani-Versene and by Wheat Leaf Enzyme

THERE is little agreement concerning either the pathway or the final products of the enzymic oxidation of heteroauxin[1]. The stoichiometry of the oxidative decarboxylation seems to be reasonably well established[1], one mole of oxygen being taken up and one of carbon dioxide evolved for every mole of indole-3-acetic acid (IAA) reacting. Galston[2] reported that no indole-3-aldehyde was formed when IAA was destroyed by a pea brei (see, however, Racusen[3]), two principal products were formed with R_F very close to that of *o*-aminoacetophenone (I) and *o*-formamidoacetophenone (II) and giving similar colour reactions. On the basis of a ferric chloride test, Galston concluded that these compounds were hydroxylated derivatives of (I) and (II). Indole-3-aldehyde has an R_F intermediate between those of (I) and (II) and does give a brownish-pink colour with ferric chloride, the colour reported by Galston is undoubtedly due to the spot for the indolealdehyde overlapping on to the other two spots. It also seems most unlikely that the R_F of phenolic derivatives of both (I) and (II) should be the same as those of (I) and (II). Finally, should such phenols be formed, the uptake of oxygen should be at least 1.5 times that actually reported. Using an oxidizing enzyme from *Omphalia flavida*, Stowe *et al.*[4] rejected the possibility that (I), (II) or indolealdehyde was formed in any amount and suggested that the product (not isolated) might be 3-methyldioxindole. From their chemical evidence it seems rather unlikely that their product was 3-methyldioxindole. Most of their observations can be explained on the basis of our present results. With *Lupinus* seedlings Stutz[5] obtained a number of products (one of them being indolealdehyde) chromatographically similar to those obtained by Galston[2]. Using substituted 3-indoleacetic acids Stutz concluded that the ring system (probably C_2) and not the side chain was the primary site of dehydrogenation.

MacLachlan and Waygood[6] reported that the oxidative decarboxylation of IAA by mangani-versene in a phosphate buffer at *p*H 6 gave a product which appeared to be chromatographically identical with that obtained by the oxidation of IAA in the presence of wheat leaf enzyme, or by using a peroxidase in the presence of manganese ions and 2,4-dichlorophenol. Waygood *et al.*[7] also suggested a radical chain mechanism for this reaction involving the formation of a skatyl radical leading to a product $C_9H_9O_2N$ (not established) (cf. Hewitt[8]). No pure compound was actually isolated, all the conclusions being based on the rates of absorption of oxygen and evolution of carbon dioxide.

We have now oxidized IAA with oxygen in the presence of mangani-versene at *p*H 6 and isolated the basic, neutral and acidic fractions. The neutral fraction (57.5 per cent based on IAA) was analysed using paper, column, and vapour phase chromatography. By preparative vapour phase chromatography two compounds could be identified (in all cases here by analysis, melting points, mixed melting points with authentic samples, R_F values, and infra-red spectra) as *o*-aminoacetophenone (I) (very small amounts) and *o*-formamidoacetophenone (II) (9–13 per cent). Column chromatography of the neutral fraction gave *o*-aminoacetophenone (10–13 per cent) (*o*-formamidoacetophenone is hydrolysed to (I) under these conditions), followed by a small amount of unidentified crystals, melting point 164–165° (no C = O bands in the infra-red). Indole-3-aldehyde was eluted next (12.3 per cent crude yield), and, finally, a low-melting solid (25 per cent) which was chiefly 3-methyloxindole (III). It would thus seem as though all the postulated modes of primary attack are occurring in this system. Phenolic products are probably also formed (cf. ref. 9) and are present in the acidic fraction together with some unreacted IAA, but this was not investigated. Formation of 3-methyloxindole probably proceeds by primary attack at C_2 of the indole ring followed by the assisted decarboxylation of a cyclic intermediate such as (IV).



(IV) (III)

The formation of (I) and (II) is analogous to the conversion of tryptophan to kynurenine and probably involves attack at C_3 (ref. 10). The formation of indole-3-aldehyde necessitates primary attack at C_α of the side-chain.

In the case of the enzymic oxidation products[6,7] (reaction mixtures kindly supplied by Dr. E. R. Waygood) neither (I) nor (II) could be detected. Column chromatography on alumina led to the isolation in low yield of 3-methyloxindole mainly together with indole-3-aldehyde.

A preliminary investigation (with Mr. K. A. H. Adams) of the mangani-versene catalysed oxidation of

IAA at *p*H 4 gave a coloured product (melting point 160° with decomposition) which was very difficult to purify and the molecular weight of which was approximately 576 This compound gave only one spot on paper chromatography, but decomposed on alumina into three fractions A small amount of the same product also precipitates out in the *p*H 6 reaction

We wish to thank Prof Waygood for generous supplies of enzymic oxidation mixtures and the National Research Council of Canada (Prairie Regional Committee) for financial support

Complement-fixing Antibodies to Human Growth Hormone and Sheep Interstitial Cell Stimulating Hormone

PREVIOUS reports from this Laboratory[1-3] have shown that human growth hormone (HGH) and sheep interstitial cell stimulating hormone (ICSH) produce, in rabbits, precipitin antibodies that are specific to the respective hormones Immunochemical techniques have been used to characterize these hormones as well as to perform quantitative determinations of small quantities of the hormone Hæmagglutination inhibition has also been used to study and detect HGH in human serum[4] The purpose of the present investigation was to study HGH and sheep ICSH by another immunochemical reaction, namely, complement fixation It may be noted that the complement fixation method is capable of determining quantitatively as little as 0 01 μgm of the hormone and is an objective procedure which is more reproducible than the hæmagglutination technique

Rabbit antisera to HGH and sheep ICSH were produced and the γ-globulin was obtained as previously described[2,3] The procedure for the complement fixation tests was modified from that described by Kabat and Mayer[5] For a typical experiment, 0 02 μgm HGH was dissolved in 0 5 ml saline solution and 20 μgm anti-HGH γ-globulin plus 500 μgm lyophilized guinea pig serum in 0 5 ml veronal buffer of *p*H 7 3 were added. With HGH, complement fixation was carried out by incubation for an initial interval of 20 min at 37° C, followed by further incubation overnight in the refrigerator at 4° C In the case of ICSH, incubation for 1 hr at 37° C was sufficient

For the determination of uncombined complement, a suspension of hæmolysin-sensitized sheep red blood cells was added and the contents of the tubes were allowed to incubate for 1 hr at 37° C The non-hæmolysed intact red blood cells were removed by centrifugation, the clear supernatant fluid was diluted to the proper concentration for estimation of hæmoglobin concentration at 540 mμ in a Beckman spectrophotometer, model DU Increased complement fixation resulted in less hæmolysis and, consequently, a lower optical density Since the quantity of complement added is a critical step for reproducible results, a single lot of complement (Difco) with periodic titration was used in this work The amount of complement used was sufficient to lyse about 60 per cent of the sheep red blood cells in the tubes containing the lowest concentration of antigen.

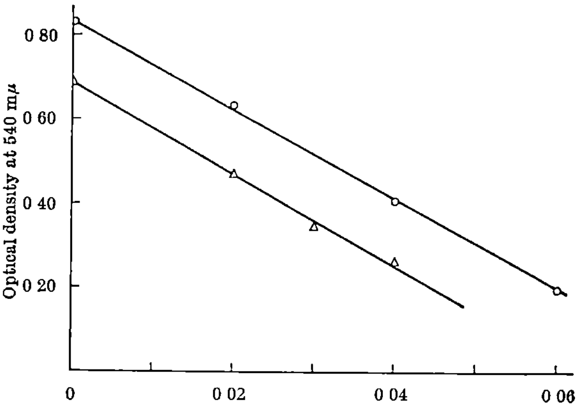

Fig 1 Amount of complement fixed as a function of human growth hormone (HGH) and sheep interstitial cell stimulating hormone (ICSH) concentrations △, HGH, ○, sheep ICSH

The standard curves, which were obtained by varying the concentration of the hormone while keeping constant the amounts of all other components of the system, are shown in Fig 1 A linear response was observed up to 0 06 μgm of ovine ICSH and 0 04 μgm of HGH The complement fixation tests were found to be reproducible if care was used in all phases of the test As a routine practice, it is always necessary to use a sufficient number of controls to detect anti-complement or synergistic activity and non-specific hæmolysis

The amount of complement fixed as a linear function of the hormone concentration suggested that the complement fixation reaction could be used as a quantitative method for determining HGH and ovine ICSH This technique has thus been employed for estimation of hormonal content in the pituitary gland Fresh pituitaries were homogenized in saline solution and the clear supernatant fluid was used The HGH content of two glands was found to be 21 3 and 31 8 μgm per mgm of fresh tissue by complement fixation and 19 3 and 36 1 μgm per mgm by quantitative precipitin tests[2] By complement fixation the HGH in three acetone-dried glands was estimated as 4 4 μgm per mgm of dry tissue and 4 1 μgm per mgm by the precipitin test[2] These results were in good agreement with values estimated on the basis of the results of the tibia test in hypophysectomized rats[6]

Similar studies were carried out for the estimation of the ICSH content in sheep pituitaries It was found that two sheep pituitaries contained 0 9 μgm and 0 8 μgm, respectively, of ICSH per mgm of fresh tissue when the content was determined by complement fixation and 1 0 μgm and 0 9 μgm, respectively, of ICSH per mgm by the precipitin test[3]

The results of this investigation demonstrate that antibodies, prepared from rabbit antisera, to highly purified preparations of human growth hormone and sheep ICSH fix complement when allowed to react with the respective antigens On a quantitative basis, the complement fixation reaction will detect about one-hundredth of the quantity of hormone measured by precipitin reactions The close agreement of the values obtained by the technique of complement fixation with those obtained by quantitative precipitin tests indicates that complement fixation can be used as a quantitative immunochemical technique for measuring minute quantities of HGH and sheep ICSH

Effect of Riboflavin on Liver Histomucoid

Isenberg and Szent-Gyorgyi[1] studied the reaction between tryptophan and tryptophan metabolites and riboflavin It was observed that free tryptophan or this amino-acid in proteins formed a complex with riboflavin The vitamin molecule takes up one electron from tryptophan and a semiquinoid riboflavin free radical is formed Those authors speculated that this complex occurs *in vivo* Since it was established by Winzler *et al* [2] that seromucoid contains tryptophan, and in view of the hepatic origin of that fraction[3], experiments were conducted by us to investigate a possible effect of riboflavin on liver histomucoid *in vivo*

Male Wistar rats with mean body weight of 135 gm were injected intraperitoneally with a freshly prepared riboflavin solution (20 mgm /100 ml of physiological saline) The dose used was 0 2 mgm of riboflavin per 100 gm of body weight One group of animals received only one injection and the other was treated with a daily dose for 7 days Control rats were injected with the same volume of the saline solution All the animals were fed *ad libitum* a standard balanced diet, and liver histomucoid determinations were carried out, by the method previously reported[4], 24 hr after the last injection A summary of the results is shown in Table 1

Table 1 clearly shows that in both riboflavin groups lowered levels of liver histomucoids were observed The differences between riboflavin-injected rats and the controls were statistically significant (1 treatment t = 3 733, P < 0 01, 7 treatments t = 4 711, P < 0 001) From the results presented it is obvious that one dose of riboflavin is sufficient for the production of the full effect

Table 1 LIVER HISTOMUCOID IN RATS TREATED WITH RIBOFLAVIN

Treatment	No of injections	No of rats	Histomucoid (mgm hexose/100 gm acetone powder) Range	Mean ± S D
Saline	1	6	105–191	152 ± 36
Riboflavin	1	6	89–108	96 ± 7
Saline	7	8	110–187	146 ± 24
Riboflavin	7	11	67–127	97 ± 20

Seromucoid determinations[3] in the same animals were carried out and no differences were disclosed between control and riboflavin-treated rats This result warrants the conclusion that the lowered liver histomucoid observed was not produced by a mobilization of mucoproteins from that organ to the plasma

On the other hand, incubation of extracts from liver acetone powders[4] or liver homogenates in physiological saline with riboflavin at 37° C up to 3 hr gave no change in the histomucoid-level

Further investigations are being undertaken to elucidate the mode of the action of riboflavin on liver histomucoids

This work was carried out with research fellowships from the National Research Council of Brazil

D-Penicillamine as an Antidote to 8-Hydroxyquinoline and Alloxan

Owing to the chelate-forming effect of its —SH and NH_2 radicals, DL-penicillamine has hitherto been used for removing copper deposited in brain tissues in cases of Wilson's disease and for preventing intoxication caused by heavy metals[1] It is, however, undesirable to use L-penicillamine as a remedy or a preventive, because of its strong toxicity which causes acute and chronic deficiency of vitamin B_6 (refs 2–4)

D-penicillamine, on the other hand, has no toxicity We have examined its preventive and remedial effects on intoxication by 8-hydroxyquinoline and alloxane, which are diabetogenic agents

0 03 mgm /gm of body-weight was determined as the lethal dose of 8-hydroxyquinoline for mice 10 hr after intramuscular injection 0 2 mgm /gm of D-penicillamine, injected 5 min before the injection of lethal doses of 8-hydroxyquinoline, prevented death of 60 per cent of the experimental animals or showed effects in retarding death Injection of 0 5 mgm /gm of D-penicillamine prevented death completely but could not prevent toxic symptoms

Table 1

No of Mice	10	10	10	10	10
D-Penicillamine mgm / body-weight (gm)	1 0	0	0 2	0 5	1 0
8-Hydroxyquinoline mgm / body-weight (gm)	0	0 03	0 03	0 03	0 03
Toxic symptoms	—	+ + +	+ +	+	—
No of mice dead	0	10	4	0	0

Table 2

No. of mice	10	10	10	10	10	3
Tested compounds mgm./body-weight (gm.)	—	D-penicillamine 1.0	DL-cystine 1.0	Vitamin B_6 1.0	Glucose 1.0	Vitamin B_{12} 0.15
Alloxan mgm./body-weight (gm.)	0.45	0.45	0.45	0.45	0.45	0.45
Toxic symptoms	+ + +	+	+ + +	+ + +	+ + +	+ +
No. of mice dead within 15 hr.	10	3	10	10	10	2

such as dyspnœa, tremor and paralysis. Injection of D-penicillamine (1.0 mgm./gm.), however, was successful in preventing death as well as all toxic symptoms (Table 1). Further, D-penicillamine injection in the same amount, 1 hr. before the lethal dose of 8-hydroxyquinoline, could also save the animals from death.

On the other hand, injection of 1 mgm./gm. of vitamin B_6, DL-cystein (hydrochloride) or glucose or of 0.15 mgm./gm. of vitamin B_{12} 5 min. before the injection of lethal doses of 8-hydroxyquinoline could not prevent death in these animals.

1.0 mgm./gm. D-penicillamine injection 5 min. before the injection of alloxane in the lethal doses (0.45 mgm./gm.) retarded death, but DL-cystein, vitamin B_6, glucose or vitamin B_{12}, injected in the amount mentioned above, could not prevent or retard death (Table 2).

8-Hydroxyquinoline injection in an amount less than the lethal dose caused the blood sugar in mice to increase by approximately 100 per cent in 1–3 hr. and, thereafter, in 6–16 hr., to decrease by approximately 40 per cent, during which time some of the mice died of intoxication. The blood sugar returned to the normal level in 24 hr. and, thereafter, in most cases showed slightly higher values than the normal. In order to test the influence of D-penicillamine upon the changes of blood sugar values brought about by 8-hydroxyquinoline, 1.0 mgm./gm. of D-penicillamine was injected 5 min. before 8-hydroxyquinoline injection, but no influence whatever was observed. Accordingly, it is considered that death caused by 8-hydroxyquinoline and the antidotal effect of D-penicillamine against 8-hydroxyquinoline has nothing to do with the changes of blood sugar values.

With regard to the mechanism of the preventive action of D-penicillamine, we are still conducting tests.

Preparation and Determination of Sulphosalicylo-soluble Proteins using Tannin

In previous papers[1–3], regeneration of proteins from insoluble protein-tannin compounds (PT) after treatment with caffeine, without loss of physico-chemical and biological properties, was reported. The present communication is concerned with determination and preparation of sulphosalicylo-soluble proteins (SSP). The proteins belonging to that group are, for example, gonadotropins, thyreotropin, orosomucoid, haptoglobin, submaxillary mucoprotein, ovomucin, lysozyme, uromucoid and acid mucopolysaccharide-containing proteins.

In this communication the turbidimetric micromethod[4] is applied to estimation of both groups of proteins, soluble and insoluble ones, in sulphosalicylic acid (SSA). It has been shown that 10–100 μgm. of dried gelatin, lysozyme, orosomucoid or mucin, dissolved in 1 ml. of 0.9 per cent sodium chloride or 0.15 *M* SSA, produce with tannin reagent similar turbidity as hæmoglobin, fibrinogen or egg albumin dissolved in 1 ml. of 0.9 per cent sodium chloride. Under conditions of the method (*p*H about 0, excess of tannin with reference to weight of protein), irreversible PT compounds are formed. Turbidities, measured as optical density, are directly proportional to the weight of proteins and do not depend on molecular weight, nitrogen content or on presence of a non-protein moiety. In this way it is possible to apply the same criterion for the determination of proteins which are soluble or insoluble in SSA, and an appropriate conversion factor should be used.

It has been shown that as well as previously investigated proteins, orosomucoid and lysozyme form reversible PT compounds at their isoelectric points and below, at a definite ratio of weight of the reactants[5]. For the precipitation of proteins at *p*H about 1(0.15 *M* SSA), 400 mgm. of tannin should be added to each 100 ml. of the solution and then an amount of tannin equal to protein content. The precipitate is centrifuged and washed with water until it is free from SSA. Lysozyme and orosomucoid, after regeneration with caffeine, retain their electrophoretic mobility and solubility in SSA unchanged. SSP can be recovered with 90 per cent yield.

Concentrations of total protein as well as that remaining in SSA filtrate have been determined in different biological materials. For example, in 100 ml. of gastric juice, normal serum or urine (without uromucoid), 0.2, 6.0 and 0.005 gm. of protein and 0.2, 0.07 and 0.002 gm. of SSP, respectively, were found[5]. Very small amounts of SSP in normal serum and urine require to be concentrated before paper electrophoresis. For that purpose, the tannin and caffeine procedure was applied[1]. SSP of serum had been concentrated 50-fold and those of urine 1,000-fold, and they were separated afterwards by paper electrophoresis. The results of one experiment in which both

Paper electrophoresis in veronal buffer of *p*H 8.6 and ionic strength 0.09 (ref. 8). Protein was concentrated by the tannin–caffeine procedure (ref. 2). Amount of SSP in 100 ml. of serum, amount of protein in 100 ml. of urine and SSP in 100 ml. of urine were, after the concentration procedure, 3.1, 1.8 and 2 gm., respectively. The results are obtained by dividing the obtained values by degree of concentration.

the protein and regenerated SSP of normal human serum and regenerated protein and SSP of normal urine were determined after paper electrophoresis are shown in Table 1 The values obtained for orosomucoid of normal human serum were strikingly similar to those of Winzler[6]

Electrophoretic paper strips of regenerated proteins and SSP of normal urine were stained for acid mucopolysaccharides with alcian blue according to Heremans and Vaerman[7] Three fractions were found with anodic mobility greater than albumin even though chondroitic acid and heparin are not precipitable with tannin The presence of acid mucopolysaccharides proves that they are precipitated together with the protein component and are then dissociating during electrophoresis

Comparative *in vitro* Activities of Phosphorylase *b* and Cytochrome Oxidase in Preparations from Two Ox Muscles

IT is generally observed that glycolysis in mammalian muscles ceases when the *p*H falls to 5 4–5 5 and that this *p*H is usually reached unless there is insufficient glycogen present in the muscle at the moment of death In some muscles, however, as much as 1 per cent of glycogen may remain unconverted to lactic acid at an ultimate *p*H of 5 9–6 0 [1,2] One such muscle is ox *sternocephalicus* It has been shown that during post-mortem glycolysis in this muscle the length of the external glycogen chains diminishes significantly Thus, while the mean number of glucose residues in external chains of glycogen molecules for ox *sternocephalicus* glycogen is 12 before the onset of *rigor mortis* (pre-rigor), the mean number of glucose residues for the residual glycogen[3] (post-rigor) is 9 the latter is apparently insusceptible to further glycolysis *in situ* In these circumstances, it was of interest to compare the behaviour of the glycogen isolated *post rigor* from ox *sternocephalicus* when exposed *in vitro* to the action of phosphorylase *b* preparations from ox *sternocephalicus* and *psoas major* muscles respectively The rate of *in vitro* breakdown of some other muscle glycogens by these phosphorylases has also been considered

The methods for preparing pre- and post-rigor samples of muscle glycogen have been described earlier[3] Phosphorylase *b* was prepared by the method of Fischer and Krebs[4], and its enzymic activity in forming glucose-1-phosphate from glycogen was measured as described by Illingworth and Cori[5] The activity of phosphorylase *b* prepared from ox *psoas major* muscles against pre-rigor glycogen from this same source has been given an arbitrary value of 100 Findings are summarized in Table 1

Table 1 RELATIVE *in vitro* ACTIVITY * OF OX PHOSPHORYLASE *b* FROM TWO OX MUSCLES WITH VARIOUS SAMPLES OF MUSCLE GLYCOGEN †

Source of phosphorylase *b*‡ preparation	Source of glycogen *Psoas major* (ox) pre-rigor	*Psoas major* (ox) post-rigor	*Sternocephalicus* (ox) post-rigor	Heart (horse) pre-rigor	Heart (horse) post-rigor
Psoas major§	100	100	80	130	95
Sternocephalicus§	100	110	75	145	115

* Rate of glucose-1-phosphate formation in a reaction mixture of 0 2 m*M* adenylic acid, 1,000 mgm per cent glycogen, 25 mgm per cent inorganic phosphate and 5 mgm per cent phosphorylase *b* protein in 0 07 *M* glycerophosphate and 0 06 *M* cysteine buffer, *p*H 6 8 Activity of *psoas major* phosphorylase *b* with *psoas major* (pre-rigor) glycogen taken as 100 = 850 units/mgm protein

† As prepared by Lawrie *et al* (ref 3)

‡ As prepared by Fischer and Krebs (ref 4)

§ Mean values of three determinations except for *psoas major* (post-rigor)

It is clear that phosphorylase *b* preparations from *psoas major* and *sternocephalicus* muscles of the ox break down a given glycogen at comparable rates Different glycogens, however, are attacked at markedly different rates by both phosphorylase *b* preparations Thus pre-rigor glycogen from horse heart is broken down at about twice the rate of post-rigor glycogen from ox *sternocephalicus* (Table 1)

The results indicate that post-rigor glycogen from ox *sternocephalicus* is broken down *in vitro* by phosphorylase *b* prepared from this same muscle This suggests that its apparent insusceptibility to attack during post-mortem glycolysis cannot be entirely explained by those structural changes in the molecule represented by the shortening of the mean number of glucose residues in external chains of glycogen molecules In this context it may be mentioned that pre- and post-rigor glycogens from horse diaphragm and *psoas* muscles have similar mean number of glucose residues, yet in both muscles there is 0 6–1 per cent of residual glycogen at ultimate *p*H values above 5 85 [3] On one hand it could mean that phosphorylase is more readily inactivated during post-mortem glycolysis in ox *sternocephalicus* than in ox *psoas* On the other hand, it could signify that, apart from the magnitude of the store of muscle glycogen, intracellular organization is a factor in determining the extent of post-mortem glycolysis It is not inconceivable that glycogen is functionally differentiated *in vivo* and that there may be concomitant specificity of localization Thus, in muscles such as ox *sternocephalicus*, some of the glycogen present *in vivo* may be inaccessible to attack under the conditions prevailing in the immediate post-mortem period

The relatively high activity of phosphorylase *b* with pre-rigor glycogen from horse heart is compatible with the rapidity of glycolysis in the latter post mortem[6] and under anaerobic conditions *in vivo*[7] Pre- and post-rigor glycogens from ox *psoas major* are apparently converted into glucose-1-phosphate at much the same rate by phosphorylase *b* preparations *in vitro* This accords with their similar branching structure[3] and with the fact that no residual glycogen is found in this muscle above an ultimate *p*H of 5 4–5 5 (ref 8).

The potential respiratory capacity of the ox *sternocephalicus* was compared with that of the *psoas major* by determining cytochrome oxidase in enzyme preparations[10] made from each (Table 2) Both the concentration of enzyme solids, and their

Table 2 COMPARATIVE DATA ON CYTOCHROME OXIDASE ACTIVITY IN ENZYME PREPARATIONS FROM OX *psoas major* AND OX *sternocephalicus* MUSCLES

Source of enzyme preparation	Cytochrome oxidase* Qo_2 mean and *S E*	Mgm dry fat-free solids/ml mean and *S E*	Calculated oxygen uptake on whole-tissue basis (µl /gm / hr)	Ultimate *p*H of muscle
Psoas major	1,146 ± 51 (5)	37 0 ± 6 0 (5)	4,770	5 51 ± 0 04 (5)
Sterno-cephalicus	1,554 ± 222 (5)	48 6 ± 6 8 (5)	8,400	5 91 ± 0 08 (5)

* Cytochrome oxidase Qo_2 max = µl oxygen/mgm dry fat-free enzyme solids/hr at infinite cytochrome *c* concentration Experimental conditions of Slater (ref 9)

intrinsic activity, were greater in the *sternocephalicus* preparations than in those from the *psoas major* As a result the potential rate of respiration due to cytochrome oxidase in the former was found to be about twice as high as that in *psoas major*, when calculated on a whole-tissue basis There tends to be an inverse relationship in muscle between respiratory capacity and the magnitude of the initial glycogen store[1,3,11] (Initial glycogen is an approximation to the *in vivo* resting value It refers to the quantity at a hypothetical initial *p*H of 7 2, calculated from the *p*H, glycogen content and buffering power of a muscle sample) Since the *sternocephalicus* has a markedly greater initial store of glycogen than *psoas major*[3], its greater cytochrome oxidase activity is unexpected This finding does suggest, however, that the glycogen store in a muscle such as ox *sternocephalicus* may serve other purposes than the production of energy by glycolysis or respiration solely from a quantitative aspect The resistance of part of this glycogen to post-mortem glycolysis, its relative resistance to phosphorylase *b* *in vitro* and its unusual branching characteristics lead to a similar conclusion

Glucose	79 ± 7 (3)	99 ± 12 (8)	32 ± 2 (18)

Slices of tissue were incubated in a calcium-free Krebs–Ringer-phosphate buffer at *p*H 7 4 with 10^{-3} *M* substrate Equilibrated with air at 37°

Results are given as means ± *S E* with the number of experiments shown in parentheses

The rate of lactic acid production, which was greater in the human gland than in either lobe of the rat prostate, was increased by added fuctose All the substrates tested on the rat glands except fructose (which was without effect) slightly raised the rate of lactic acid production These findings might be due to qualitative or quantitative differences in the cytochrome systems of the tissues (Table 2)

Table 2 EFFECT OF EXOGENOUS SUBSTRATES ON THE RATE OF LACTIC ACID PRODUCTION OF PROSTATIC TISSUE

Substrate	Lactic acid production µmoles/gm dry weight/hr Tissue Rat dorsolateral lobe	Rat ventral lobe	Human gland
Nil	23 ± 4 (3)	17 ± 1 (5)	90 ± 19 (9)
Succinate	—	24 (2)	65 ± 14 (5)
Fructose	19 (2)	15 (2)	120 ± 10 (6)
Pyruvate	39 ± 6 (4)	27 ± 3 (6)	86 ± 25 (7)
Glucose	31 ± 3 (3)	24 ± 4 (3)	80 ± 10 (18)

Conditions were as shown in Table 1

Homogenates in phosphate-saline buffer at *p*H 7 4 were prepared from the glandular portions of human adenomatous prostate, and from the separated dorsolateral and ventral lobes of the rat prostate, reduced with sodium dithionite and examined by the Beck–Hartree microspectroscope Both lobes of the rat gland showed absorption bands with maxima at 550 mµ, 562 mµ and 600 mµ, corresponding to the maxima of cytochromes *c*, *b* and *a* The bands were also produced by the addition of succinate to cyanide-treated preparations, suggesting enzymic reduction of cytochromes Homogenates from human glands chemically or enzymically reduced showed strong bands of cytochrome *b* and weaker bands of cytochrome *a* Cytochrome *c* was not detected with certainty, and, if present, its concentration was considerably less than those of cytochromes *b* and *a* The cytochrome *b* bands in all preparations disappeared on heating in a boiling water-bath for 5 min

Fresh normal human prostates have not been available for examination, but the absence or relatively low concentration of cytochrome *c* in the human adenomatous tissue might either be related to the mechanism of adenomatous change, or an adaptive response to hypoxia in the poorly vascularized hypertrophied gland (cf the decrease in the concentration of cytochrome *c* in diaphragm during hypoxia[2])

We wish to thank the British Empire Cancer Campaign for a grant to support the work

An Unusual Major Fatty Acid Component in Human Depot Fat

THE technique of gas chromatography has shown that naturally occurring fats and waxes contain saturated and unsaturated fatty acids with both even and odd numbers of carbon atoms. So far, however, the acids with odd numbers of carbon atoms have been reported to occur in only relatively small amounts in natural materials.

During analysis of human depot fat being carried out at this Institute, one specimen was shown to contain 8.7 per cent of a branched chain fatty acid containing thirteen carbon atoms. Other specimens of depot fat we have examined have always contained less than 0.1 per cent of this acid. The analysis showed no other abnormal features. The fat was obtained from the abdominal wall of a male African of the Sukuma tribe, whose approximate age was 60 years, admitted to hospital suffering from a strangulated hernia. The material was treated by the method described by Kingsbury *et al.*[1] and 0.1 µl. of the resulting methyl esters was applied to a 4-ft. column of 20 per cent 'Apiezon *L*' grease on 100–120 mesh 'Celite' held at a temperature of 186° C. Argon was used as the carrier gas and the effluent gas was passed through a Pye ionization detector. The methyl ester of the component emerged from the column with a retention volume of 0.256 relative to methyl palmitate. With these conditions the relative retention volume of *n*-tridecanoic acid was 0.307. The amount of material available was too small to allow the nature of the acid to be determined accurately, but as the peak corresponding to the acid still appeared on the trace after bromination by the method of James and Martin[2] it must be considered to be a saturated acid.

We are unable to explain the presence of the large amount of this acid in this specimen, but since it is most unlikely to occur to any extent in the diet, we suggest that its presence is due to an unusual method of fatty acid synthesis in the body.

Blood Glucose-6-Phosphate in Heterozygous Carriers and Patients with Liver Glycogen Disease (Von Gierke's Disease)

Hsia and Kot[1] have reported that children with liver glycogen disease (von Gierke's disease) and their parents, presumably heterozygous for the disease trait, both have high levels of glucose-6-phosphate and fructose-6-phosphate in red blood cells. If correct, this observation would have very important practical as well as theoretical implications. It would greatly simplify the diagnosis and study of this disease and would open the possibility of its control through a eugenic approach. However, Hsia and Kot presented no evidence that their analytical methods were appropriate or that the materials they measured were in fact glucose-6-phosphate and fructose-6-phosphate. Furthermore, the values these authors cited for their normal control population (glucose-6-phosphate, 50–370 mgm. per 100 gm. red blood cells, fructose-6-phosphate, 120–570 mgm. per 100 gm. red blood cells) are much higher than those reported by other investigators[2,3] or expected from theoretical considerations. Accordingly, their findings seemed questionable. We have re-examined this problem with respect to glucose-6-phosphate, using a specific enzymic analytical method. Our results are in sharp disagreement with those of Hsia and Kot.

Samples of whole blood or sedimented erythrocytes were deproteinized with equal volumes of 7 per cent perchloric acid. The filtrates were neutralized with potassium hydroxide and aliquots were incubated with glucose-6-phosphate dehydrogenase and triphosphopyridine nucleotide (TPN). The procedure of Aisenberg[4] was followed, except that 300 µgm. of TPN was used and the total volume of the incubation mixture was reduced to 0.5 ml. The reaction was conducted in microcuvettes. The procedure was applied to standard solutions of glucose-6-phosphate, production of reduced TPN was within 6 per cent of the expected amount. The method was then tested by determining glucose-6-phosphate in whole blood to which different amounts of glucose-6-phosphate had been added. The results are shown in Table 1. There was some loss of added glucose-6-phosphate, presumably due to catabolism during the interval between addition of the material and inactivation of enzymes in the blood. However, recoveries were in a satisfactory range and reproducibility was good, down to concentrations of about 1 mgm./100 ml. Below this level, the procedure proved inaccurate because the increases in optical density during incubation were very small.

Table 1. RECOVERY OF GLUCOSE-6-PHOSPHATE ADDED TO WHOLE BLOOD

Manipulations were carried out at room temperature, time interval before addition of perchloric acid was about 2 min. In each experiment the glucose-6-phosphate concentration was determined in an aliquot of blood to which none had been added and the recovery results were appropriately corrected

Glucose-6-phosphate (mgm./100 ml.) Added	Recovered	Recovery (per cent)
6.4, 6.4, 6.4	5.5, 5.7, 5.6	84, 89, 88
3.2, 3.2, 3.2	3.1, 2.6, 2.9	97, 81, 91
1.6, 1.6	1.4, 1.4	88, 88
0.64, 0.64, 0.64	0.72, 0.53, 0.53	112, 82, 82
0.32, 0.32, 0.32	0.21, 0.34, 0.37	66, 107, 115
0.16, 0.16	0, 0.21	0, 131

Table 2 presents the results obtained on whole blood and/or sedimented erythrocytes in 3 children with von Gierke's disease, 4 parents and 12 other blood relatives of such children, and 11 healthy adults without a family history of the disease. In all cases, the concentrations of glucose-6-phosphate were near the lower limit measurable by the method and much below those reported by Hsia and Kot. There were no major differences among affected children, their parents, other relatives, and normal controls. Because our analytical method was inaccurate at these low concentrations, however, it was not deemed worth

Table 2. GLUCOSE-6-PHOSPHATE IN BLOOD OF CHILDREN WITH VON GIERKE'S DISEASE, RELATIVES OF SUCH CHILDREN, AND NORMAL ADULTS

Relatives examined include 4 parents, 3 grandparents, 4 aunts or uncles and 5 siblings

	Whole blood (mgm./100 ml.)	Red blood cells (mgm./100 ml.)
Affected children		
Case 1	0.4	1.0
Case 2	0.7	—
Case 3	—	0.8
Relatives of affected children, range	< 0.3–0.7 (8 individuals)	< 0.3–0.5 (8 individuals)
Normal controls, range	< 0.3–2.0 (11 individuals)	< 0.3–0.8 (8 individuals)

while to calculate means and standard errors, and our results do not exclude the possibility that small differences between some of these groups may exist

The recovery data shown in Table 1 indicate that we would not have failed to find the concentrations reported by Hsia and Kot for their normal controls, to say nothing of the very high values these authors reported for affected children and their parents Our values are roughly of the same order of magnitude as those reported by Bartlett[2], who undertook a painstaking analysis of glycolytic intermediates in human red blood cells, using carefully controlled column chromatographic techniques for the separation of individual compounds and identifying each fraction obtained by appropriate chemical methods Bartlett obtained the following values in 14 healthy adults glucose-6-phosphate, 0 08–0 10 µmole per ml red blood cells (2 1–2 6 mgm per 100 ml), fructose-6-phosphate, 0 01–0 02 µmole per ml red blood cells (0 26–0 52 mgm per 100 ml)

Hsia and Kot reported normal erythrocyte concentrations of glucose-6-phosphate and fructose-6-phosphate which are up to six times as high as the normal level of glucose The concentrations proposed for heterozygous carriers (who have no obvious clinical abnormalities) and for children with von Gierke's disease are ten to fifteen times the normal glucose concentration These values are far outside the range expected from theoretical considerations or found by other investigators Since Hsia and Kot offered neither recovery data as a check on their analytical technique nor evidence that the materials measured were indeed glucose-6-phosphate and fructose-6-phosphate, we are forced to conclude that they were measuring something other than these phosphorylated hexoses and that a method for the detection of heterozygous carriers of von Gierke's disease is not yet at hand

DURING the past year, we have attempted to improve the methodology using two different approaches I would like to summarize the results obtained up to the present time

In all experiments, equal volumes of 10 per cent trichloroacetic acid were added to whole blood and the precipitate removed by centrifugation The supernatant was then extracted four times with ether or until neutral, and the ether removed by evaporation

In the first series of experiments, glucose-6-phosphate was measured directly by incubation with yeast glucose-6-phosphate dehydrogenase (Sigma) and TPN, and observing the conversion of TPN to TPNH in the Beckman spectrophotometer at 340 mµ Recoveries of glucose-6-phosphate added to normal red cells was somewhat variable, with ranges from 76 to 111 per cent being obtained in successive experiments Using this technique, the range of values for 6 normal controls was 0 23–0 74 mgm /100 ml red blood cells (all values have been expressed on the basis that the hexose phosphates are intracellular) In two patients with von Gierke's disease, the values were respectively 0 44 and 0 72 mgm /100 ml red blood cells These findings are essentially in agreement with those of Sokal *et al*

In the next series of experiments, the total hexose monophosphates were determined in the following manner The evaporated ether extract was passed through 'Dowex 50 × 8 (50–100)' and washed with 25 ml water This was neutralized with ammonium hydroxide and put through a 'Dowex 1 × 8 (50–100)' column and washed with 50 ml water The resin was eluted with 80 ml. 0 02 *N* hydrochloric acid and the total hexose determined by anthrone Recovery for glucose-6-phosphate was 101 per cent Using this technique, the range for normal controls was 1 04–1 77 mgm /100 ml red blood cells The values for two mothers were 1 74 and 1 85 mgm /100 ml red blood cells, and for five children with von Gierke's disease were 1 04, 1 59, 1 87, 2 07, and 2 20 mgm /100 ml Thus, three of the affected children and one of the mothers had levels in excess of the upper limits of the normal range These findings are compatible with those previously reported by Wagner *et al* [1] and from our laboratory

In reviewing the communication by Sokal *et al* , one should evaluate critically two points First, there is considerable doubt as to whether the conversion of TPN to TPNH at 340 mµ can be used as a satisfactory means of measuring glucose-6-phosphate at such low ranges In particular, I feel that the values by this method tend to run low Secondly, the authors have failed to take into account the action of phosphatases and other enzymes on glucose-6-phosphate in the erythrocytes of normal individuals[2] and in those with von Gierke's disease In experiments with normal red cells, we have observed changes of glucose-6-phosphate upon standing at room temperature during a period of 1 hr The results of Sokal *et al* in Table 2 would seem to support this In their experiments, the whole blood was deproteinized within 2 min , while the packed red cells had to be separated by sedimentation or centrifugation involving at least 20–30 min It can be seen that in case 1, this procedure had little or no effect, since the packed red cell values are approximately twice that in whole blood On the other hand, in the normal controls the value in the packed red cells, instead of being about twice the range in whole blood, is in fact about half, indicating roughly a four-fold decrease

We[3] have recently prepared an enzyme system in red cells which hydrolyses glucose-6-phosphate Assays were carried out using a mixture of 1 ml of 1 1 hæmolysate and 1 ml 0 04 *M* histidine buffer at 5 0 containing 75 μM of glucose-6-phosphate and 100 μM of ethylene diamine tetraacetate and incubated for 2 hr at 37° C The glucose that was liberated was measured by glucose oxidase Duplicate assays showed variations of less than 5 per cent by this method The activity in 15 normal controls averaged 17 ± 2 7 mgm glucose liberated/hr /100 ml red blood cells, while in 8 patients with glycogen storage disease and their parents, it averaged 14 ± 2 7 The demonstration of an erythrocyte enzyme system which hydrolyses glucose-6-phosphate and a significant decrease of activity among patients and their parents explains our earlier findings.

PHYSIOLOGY

Prolonged Biological Half-Life of Sodium-22 in Patients with Essential Hypertension

IN the treatment of hypertension, the effectiveness of sodium depletion by either dietary restriction or natriuretic agents is now fully documented It is sufficient to say that the response to such treatment led to the hypothesis that hypertensives might suffer from an abnormality in sodium metabolism The first measurements of the sodium content of individuals with hypertension were done in 1951 by the technique of isotopic dilution using sodium-24[1] With the exception of one report these observations have been confirmed repeatedly by ourselves and by others · an increase in sodium was not evident In the single discordant report[2], some cases of severe hypertension were noted to have an increase in exchangeable sodium, but this was interpreted as being secondary rather than primary to the disease, because it was observed almost exclusively in individuals with advanced hypertension

In 1953 it was reported that when the average salt-consumption of rats was increased the mean systolic pressure increased linearly[3] Observations on human beings have shown a similar type of correlation as the average salt-consumption of a community increases, the prevalence of hypertension increases linearly[4] Such observations have been interpreted to indicate that chronic excess salt consumption plays a primary part in the ætiology of human hypertension[5] In view of these considerations, the apparent absence of measurable increase in body sodium in patients with hypertension has been subjected to new scrutiny

During the past two years we have explored further the sodium metabolism of patients with and without hypertension using sodium-22 (physical half-life, 2 6 years) instead of sodium-24 The results suggest that hypertensives probably do have an abnormality in sodium metabolism

Fifteen adult patients, none of whom had had symptoms or signs of cardiac or renal failure, were studied Seven patients had 'essential' hypertension whereas the other 8 had unrelated diseases with normal blood pressure These investigations were carried out while the patients were in a metabolic ward and were consuming a constant diet which contained about 250 mgm of sodium chloride by analysis After the dietary regimen had been established, sodium-22 (usually 2–4 μc) was given orally and the total body burden of this isotope was recorded every 1–3 days by means of a whole-body counter[6] Thereafter the patient's daily intake of salt was increased by 2, 5 or 10 gm, at which level it remained for 2–4 weeks without other change in the regimen Some patients served as subjects for more than one level of salt increment The addition of this salt resulted in a prompt increase in the rate at which sodium-22 was lost from the body, manifested by a decrease in total body counts On any given salt intake, the rate of decline in counts proved to be steady and relatively predictable for each patient At each of the three levels of salt ingestion, the hypertensive individuals, without exception, lost sodium-22 significantly more slowly than did those without hypertension ($P < 0\ 01$) This is shown in Table 1, where the rate of loss of sodium-22 is described in terms of its 'biological half-life'

There are at least three possible explanations for the slower excretion of the sodium-22 in hypertensive subjects (1) The metabolism of sodium-22 differs from that of sodium-23 in hypertensives This seems most unlikely (2) Hypertensives absorb less of the supplementary sodium chloride This was disproved by measurements of the urinary excretion of sodium. (3) Hypertensives have more sodium in the body, that is, they have a larger 'metabolic pool' of sodium Obviously, the last-named hypothesis merited re-investigation in spite of the repeated evidence to the contrary cited above

The original calculations of total exchangeable sodium were based on actual weight[1] However, recent unpublished observations which were made on obese hypertensive females during sharp decline in

Table 1

* More than one value indicates additional periods of study which were not performed sequentially For such individuals the average of these values was used in calculating mean and standard deviation of the group

† For hypertensive versus normotensive subjects on equal sodium chloride intakes

weight had frequently shown negligible loss of exchangeable sodium despite weight losses of 20–50 kgm This indicated that the fat deposits in such people had a low sodium content Therefore the calculations based on actual weight might have been misleading if the average hypertensive person had been fatter than the average non-hypertensive subject Hence, body sodium content was recalculated on the basis of two approximations of 'lean body mass' This brought into evidence that the hypertensives appeared to have an increase in tissue sodium One approximation was based on 'desirable' body weight as defined from a recent large actuarial study[7], while in the second, exchangeable sodium was expressed with reference to body potassium The latter was derived from the amount of naturally occurring potassium-40 present in each patient as determined by a total body radiation counting technique[8]

The evidence seems unequivocal that individuals with essential hypertension have a prolonged biological half-life for sodium 22 Our preliminary calculations suggest that this is the result of hypertensive patients having a large metabolic pool of sodium These findings lend support to the thesis that sodium is intimately involved in the hypertensive process[4,5]

Modification of the Inotropic Activity of Calcium by Potassium

In previous communications from this laboratory[1,2], results have been presented which suggest that the accumulation of calcium at specific sites on or about the membranes defining individual cardiac cells may provide the fundamental basis for the conditions of enhanced contractility recorded during post- and extra-systolic potentiation and throughout the classical staircase[3] These results confirmed the earlier observations of Niedergerke[4] and support the hypotheses of Sandow[5], of Csapo[6], and of Bianchi and Shanes[7], who maintain that entry of calcium associated with the depolarization stage of activation is involved both in the link between excitation and contraction and in the regulation of the contractile force Hajdu and Szent-Gyorgyi[8], however, having observed that the staircase in isolated perfused frog hearts was abolished by reducing the potassium concentration, $[K^+]$, of the perfusate suggested that progressive loss of potassium from the myocardium during successive beats of the staircase provided the basis for the increased contractility

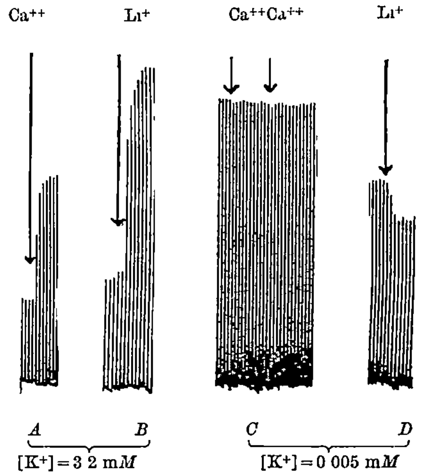

Fig 1 *A* and *B* Positive inotropic response recorded following *A*, increase of perfusate $[Ca^{++}]$ from 0 65 to 2 6 m*M* when $[K^+]$ was 3 2 m*M* (Ca^{++} added at arrow), *B*, replacement of half the perfusate Na^+ by Li^+ (at arrow) when the perfusate $[K^+]$ was 3 2 m*M*

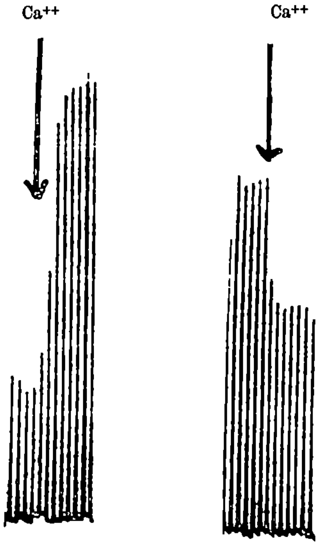
C and *D* Change in contractile force recorded in same preparation as used in *A* and *B* following *C*, increase of perfusate $[Ca^{++}]$ from 0 65 to 2 6 m*M* when the perfusate $[K^+]$ was reduced to 0 005 m*M*, *D*, replacement of half the perfusate Na^+ by Li^+ when the perfusate $[K^+]$ was 0 005 m*M*

A possible link between the hypothesis involving changed $[K^+]$ formulated by Hajdu and Szent-Gyorgyi, and that involving the accumulation of calcium as postulated by Niedergerke and others, has recently been noted in a series of experiments in which the action of calcium on the contractile behaviour of isolated toad ventricles perfused with Ringer's solution containing varying $[K^+]$ was studied

In these experiments ventricles removed from summer, non-hibernating toads of the species *Bufo marinus* were stimulated at a constant rate of 6 beats/min using supra-maximal rectangular pulses delivered from a 'Tektronix' square-wave generator Isotonic contractions detected by the photo-electric method previously described[9] were recorded on a direct-writing recorder and the ventricles initially perfused for a standard 60 min equilibration period with Ringer's solution containing 3 2 m*M* K^+ and 0 65 m*M* Ca^{++} Following this preliminary perfusion, addition of Ca^{++} (as $CaCl_2$) to give a final $[Ca^{++}]$ of 2 6 m*M* resulted in an immediate well-defined positive inotropic response (see Fig 1*A*) Such an increase in contractile force would be anticipated from the classical experiments of Ringer[10] Similarly, replacement of half the perfusate Na^+ by an isotonically equivalent amount of Li^+ (as LiCl) evoked an immediate positive inotropic response (Fig 1*B*)

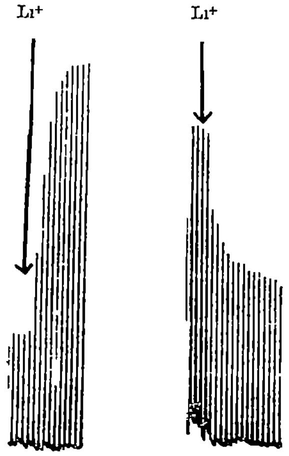
Reduction of the perfusate $[K^+]$ from the original level of 3 2 m*M* to 0 005 m*M* profoundly modified these positive inotropic responses recorded in the presence of 3 2 m*M* K^+ when the perfusate $[Ca^{++}]$ was increased or the $[Na^+]$ decreased Thus when the perfusate $[K^+]$ was reduced to 0 005 m*M*, increasing the $[Ca^{++}]$ from the original 0 65 m*M* to 2 6 m*M* either failed to alter the contractile force or in some preparations slightly decreased it (see Fig. 1*C*) In the presence of this low $[K^+]$, replacement of half the perfusate Na^+ by Li^+ without any attendant change in tonicity reduced the amplitude of contractions (see Fig 1 *D*)

The negative inotropic response which was recorded when the $[Ca^{++}]$ of the perfusate was raised from a



A $[K^+] = 3{\cdot}2$ m*M*　　*B* $[K^+] = 0$ m*M*

Fig. 2. Changes in contractile force recorded in a single preparation following the addition (at arrow) of Ca^{++} to give a final concentration of 2·6 m*M* when the perfusate contained *A*, 3·2 m*M* K^+, *B*, K^+ deleted



A $[K^+] = 3{\cdot}2$ m*M*　　*B* $[K^+] = 0$ m*M*

Fig. 3. Changes in contractile force recorded from a single preparation following replacement (at arrow) of half the perfusate Na^+ by an isotonically equivalent amount of Li^+ when *A*, perfusate contained 3·2 m*M* K^+, *B*, K^+ deleted from perfusate

preliminary level of 0·65 m*M* to 2·6 m*M* or when the $[Na^+]$ was halved was further enhanced by the use of a K^+-free perfusate. A typical result is shown in Fig. 2*A* and 2*B*, where the positive inotropic response recorded, following the above increase in perfusate $[Ca^{++}]$ in the presence of 3·2 m*M* K^+, is compared with that recorded from the same preparation following a similar increase in $[Ca^{++}]$ in the absence of any perfusate K^+. Similarly, replacement of half the perfusate Na^+ by Li^+ depressed the contractile activity when K^+-free perfusate was used (see Fig. 3*A* and 3*B*). In these particular experiments using the K^+-free solution it was necessary to replace repeatedly the K^+-free perfusate throughout the preliminary perfusion so that K^+-loss from the myocardium associated with successive contractions would not ultimately result in an appreciable perfusate $[K^+]$.

From these results it seems possible that the failure of Hajdu and Szent-Gyorgi to record the classical staircase in the absence of K^+ may reflect the need for the presence of a critical perfusate $[K^+]$ for Ca^{++} to exert a positive inotropic effect on cardiac muscle. The findings of Hajdu and Szent-Gyorgyi, therefore, do not preclude the involvement of calcium in the staircase and other conditions of enhanced cardiac contractility.

Free Amino-Acids in Rachitic Epiphyseal Cartilage of Albino Rat and the Influence of Vitamin D

It was suggested by Dikshit and Patwardhan[1] that administration of vitamin D imparted an enhanced calcifying capacity to rachitic bone and cartilage. Histochemical work by Ramalingaswami *et al.*[2] on cartilage in rickets and during healing under the influence of vitamin D, revealed an alteration in the staining characteristics of the cartilage matrix on the basis of which they suggested that vitamin D influenced the glycoprotein of the rachitic cartilage matrix. Dikshit[3] observed a decrease in the hexosamine content of the rachitic cartilage during healing induced by the administration of vitamin D. It was felt desirable, therefore, to investigate whether vitamin D influenced the protein metabolism of the cartilage. The effect of vitamin D on the free amino-acids of rachitic cartilage was studied as a preliminary to such investigations.

Young albino rats, 4 weeks old, were fed a low-phosphorus rachitogenic diet[4] for 14 days and then divided into 3 groups taking litter and sex-distribution into account. Each rat in group 3 received a single dose of 4,000 i.u. vitamin D orally on the fourteenth day and those in group 2 on the sixteenth day. Rats in group 1 received no vitamin D and served as rachitic controls. On the eighteenth day, 4–12 rats from each group were killed and their tibial epiphyseal cartilages removed, pooled according to groups, and weighed. The weighed cartilage was extracted exhaustively with 75 per cent ethanol, the collected extracts were evaporated and dried, and the residue was extracted again with 95 per cent ethanol. The residue from the second extract after evaporation was dissolved in 10 per cent isopropanol.

Using phenol/isopropanol/water (70 : 5 : 25) in presence of 0·3 per cent ammonia as the developing solvent, serine, glycine, threonine, glutamic acid and glutamine were separated from the mixture of free amino-acids contained in the isopropanol solution of cartilage extracts. Circular paper chromatographic procedure was used as described by Giri *et al.*[5] for

Table 1 EFFECT OF VITAMIN D ON THE FREE AMINO-ACIDS OF RACHITIC RAT CARTILAGE

Amino-acid		Rachitic controls (no vitamin D) I	Treated rats (4,000 I U vitamin D/rat) After 48 hr II	After 96 hr III
Glutamic acid	Mean	222	194*	222†
	S E	± 4 1	± 2 5	± 7 2
Serine	Mean	14 3	18 8*	24 2*†
	S E	± 1 45	± 0 39	± 0 51
Glycine	Mean	68	80	99*
	S E	± 2 1	± 4 7	± 6 5
Threonine	Mean	17 0	10 8*	15 5†
	S E	± 1 49	± 0 78	± 1 12
Glutamine	Mean	124	104*	122†
	S E	± 1 8	± 2 3	± 4 2

Values denote μgm of amino-acid/100 mgm fresh tissue
* Difference significant from group I below 5 per cent level
† Difference significant from group II below 5 per cent level
Each value is a mean of 3 observations, each observation was on cartilage pooled from 4–12 rats

quantitative determination of these amino-acids Duplicate values at three concentration-levels were obtained and only those in which there was good agreement within 5 per cent selected

Results shown in Table 1 revealed that administration of vitamin D affected the concentration of some free amino-acids in the rachitic cartilage While serine and glycine showed a gradual increase during healing, glutamic acid, glutamine and threonine showed an initial decrease by 48 hr followed by a rise to the pre-treatment level at 96 hr These different trends observed preclude the possibility that other simultaneous changes in the cartilage, for example, changes in the concentration of calcium and phosphorus[6], are the cause of the observed changes in the concentration of the free amino-acids

Thus there appears unmistakable evidence that protein metabolism in the rachitic epiphyseal cartilage altered under the influence of vitamin D

Failure of the Purified Growth Hormone to restore the Size of the Kidneys in Hypophysectomized Rats

IN previous work the effect of hypophysectomy on the size of the remaining kidney after unilateral nephrectomy was investigated in dogs and rats[1] After hypophysectomy rats, unlike dogs, lose weight or fail to grow normally It is, therefore, difficult to assess whether the failure of the remaining kidney to hypertrophy is a non-specific effect or the result of a deficiency of (a) particular hormone(s) Bearing this in mind, it seemed necessary to study the effect of growth hormone

Young male rats, weighing between 35 and 120 gm , were hypophysectomized by the parapharyngeal approach Of the hypophysectomized animals, one group (six rats) received growth hormone while another group (ten) was untreated After the operation the animals were given drinking water containing glucose and, in addition to the ordinary rat diet, brown bread, milk and glucose were given

Purified growth hormone was dissolved in faintly alkaline isotonic solution of sodium chloride and was injected beneath the skin twice a day with a 7-hr interval between the two injections, in doses indicated in Table 1

Table 1 EFFECT OF SUBSTITUTING GROWTH HORMONE ON THE WEIGHT OF THE KIDNEY OF HYPOPHYSECTOMIZED RATS

Body-weight (gm)		Weight of both kidneys (mgm)	Remarks
Initial	Final		
46	102	676	Injected with 2 mgm growth hormone for 20 days
54	182	831	
35	86	823	
84	124	843	Injected with 4 mgm growth hormone for 20 days
115	192	1,350	
72	148	1,035	

Grant from N H I (United States), N I H -*GH-B*2 (bovine growth hormone), growth potency, 1 53 × U S P reference standard, contamination LH, 0 01, follicle stimulating hormone, 0 009 U S P , prolactin, 0 33 I U , adrenocorticotrophic hormone, 0 25 U S P , thyroid stimulating hormone, 0 009 U S P

The animals were killed with ether on the twenty-first day after hypophysectomy The sella turcica was carefully examined for any remnants If the pituitary was completely removed, the sella turcica was seen to be covered with a smooth glistening layer of the meninges, beneath which a central depression in the bone, representing the site of the drill hole, was seen

From Table 1 it would appear that the growth hormone was effective in promoting growth in the hypophysectomized rats and the rate of growth in the treated animals was quite comparable with that of normal animals The adrenals and testes, however were found to be lighter in weight than in the normal controls In contrast to these findings, the kidneys of hypophysectomized rats receiving growth hormone were found to be the same size as those from the untreated hypophysectomized animals This conclusion was reached as a result of expressing kidney size as the ratio of kidney weight to body-weight Statistical analysis of the results showed that there was no significant difference in kidney size between the hypophysectomized group and the group which was treated with the hormone, but that there was a significant difference between these two groups and the control normal group (Table 2) It is interesting that the stomach weight and gastric mucosa were found restored completely to normal in the hypophysectomized animals and those treated with growth hormone (Crean, G P , personal communication) It can be seen that injections of the purified growth hormone can maintain the growth of the hypophysectomized rat, but are unable to prevent the relative shrinkage of the kidney that occurs after this operation This is contrary to results with the crude extract of the adenohypophysis[1]

Depression of kidney functions and blood-flow are known to occur after hypophysectomy[2,3] Unlike adenohypophysial crude extract, gonadotrophic hor-

Table 2 EFFECT OF GROWTH HORMONE ON KIDNEYS OF HYPOPHYSECTOMIZED MALE RATS

No of rats	Condition of rat	Kidney weight in mgm /body-weight in gm Mean (± *S D*)	Statistical significance
13	Normal	9 533 (± 2 14)	*P* 0 01
10	Hypophysectomized	7 461 (+ 0 84)	None
6	Hypophysectomized, growth hormone	6 931 (± 1 59)	*P* 0 01

mone, thyroid stimulating hormone and adrenocorticotrophic hormone, when given individually, are unable to restore kidney function completely to normal.

From these results it seems unlikely that an explanation in terms of hæmodynamic changes[4] of the failure of the kidney to grow is correct, for the kidney remained small in hypophysectomized rats even when the animals grew at a normal or slightly greater than normal rate. It is more likely that there is a deficiency of a pituitary hormone without which the kidney cannot well maintain its size and growth in the hypophysectomized animals. It would appear, from this work, that growth hormone is unlikely to be the only deficient hormone.

The following acknowledgments are made: Dr. J. A. Loraine for his criticism and facilities for work, Dr. A. E. Wilhelmi for supplying the growth hormone, Dr. K. E. Kirkham for work on statistics, Dr. E. B. Roberts for reading the manuscript, and Mr. J. Lowe for animal care-taking.

Effect of Urea Ingestion on Parotid Salivation in Sheep

Urea is the most common source of non-protein nitrogen used for the partial replacement of protein in the diet of ruminants. In association with readily available carbohydrate such as molasses, urea is used to supplement the low-quality roughage diets which are often consumed by ruminants in Africa, the United States and Australia.

This form of supplementation results in an increase in the rate of cellulose digestion in the rumen[1]. Food intakes are increased by approximately 30–40 per cent, live-weight losses are decreased, and wool production is increased[2–5].

Balch and Johnson[6] found a correlation between the fluidity of the rumen contents and the rate of cellulose digestion. It is therefore important to know if the volume of saliva secreted is altered when urea and molasses are added to a roughage diet.

The volumes of parotid saliva secreted by two Merino wethers were measured by means of permanent unilateral parotid fitulæ. Each sheep weighed approximately 40 kgm. and they were kept in electrolyte balance by allowing them to drink their own saliva.

The basic diet consisted of oaten straw containing 2 per cent crude protein. The supplement of urea (25 gm.), molasses (200 gm.) and water (200 gm.) was intimately mixed with straw (600 gm.) to make up the daily ration. This supplement raised the nitrogen content of the straw to the equivalent of 11 per cent crude protein.

One sheep received straw only, while the other received straw plus the supplement. After two weeks of recordings, the diets were reversed. The unsupplemented straw was offered without stint and the daily intake per sheep was approximately 500 gm. The intake of straw when fed with the supplement was restricted by offering only 600 gm. of straw plus the supplement. On every occasion this ration was completely consumed.

The volumes of saliva secreted did not alter significantly with the addition of the supplement. The average volumes for each animal were 2,160 and 2,560 ml. without the supplement, and 2,250 and 2,380 ml., respectively, with the supplement.

The mean total nitrogen of the saliva from each animal rose from 2.9 and 4.2 mgm. nitrogen/100 ml. to 12.1 and 13.3 mgm. nitrogen/100 ml. respectively, when the supplement was added to the straw.

It is concluded that the increased rate of passage of food through the alimentary tract, and the increased rate of cellulose digestion in the rumen, which are brought about by urea feeding, are not associated with quantitative changes in the pattern of parotid salivation. In the present work the urea supplement produced an increase of 20 per cent in the consumption of straw, but this was not accompanied by any increase in parotid salivation.

A reasonable estimate for the total volume of saliva secreted by each sheep would be 10 l. a day[7]. Also, it has been shown that the nitrogen content of this total salivary secretion, excluding mucoprotein, is similar to that of parotid saliva[8]. Since the total nitrogen content of parotid saliva was raised by 10 mgm./100 ml. on feeding urea, the increase in saliva nitrogen represents an overall increase in nitrogen economy to the sheep of only about 1 gm. nitrogen a day.

Therefore, the influence of urea supplementation on the parotid secretion does not seem to be particularly important from either the qualitative or quantitative point of view.

I thank the Australian Dairy Produce Board for the financial assistance that made this work possible.

HISTOCHEMISTRY

Relationship between Tissue Eosinophils and Peroxidase Activity

Four different peroxidase enzymes have been found in mammalian organisms: lactoperoxidase, myeloperoxidase, hepatic tryptophan peroxidase and labile peroxidase of the thyroid gland. There is insufficient knowledge of the physiological significance of these enzymes for animal organisms. This applies especially to the myeloperoxidase found in the granules of leucocytes[1,2].

It has been shown histochemically that the peroxidase activity possessed by eosinophils in the rat differs from other granulocytes[3]. This enzyme is very resistant in eosinophils to the effect of, say, formalin, ethyl and methyl alcohol and other agents of similar type and it is therefore possible to demonstrate it specifically by histochemical methods. It can, however, be asked whether this enzyme is a myeloperoxidase at all.

The highest peroxidase concentrations of the extramedullary organs of the rat have been established in the small intestine, uterus, large intestine, spleen, lungs and stomach[3] It is in these same organs that the relatively highest extra-medullary eosinophil counts have also been established in the rat[2] It has also been observed that both the peroxidase concentration[4] and the number of eosinophils[2] increase clearly in the rat uterus under the influence of œstrogen stimulation It is thus possible that the high peroxidase content of the organs mentioned derives from eosinophilic granulocytes

The observation that the peroxidase enzyme in rat uterus is in its behaviour like lactoperoxidase[4] —and not like myeloperoxidase—agrees well with the histochemical differences existing between eosinophils and other granulocytes

The views cited are supported by the fact that physiological, intense eosinophilia appears in lactating lactiferous gland[5]

The high peroxidase concentration established *in vitro* in the gastrointestinal tract, uterus, spleen and lungs is probably caused by the eosinophil granulocytes of tissues The enzyme contained in the eosinophils resembles lactoperoxidase

PATHOLOGY

Acid Extract of Leucocytes and *Staphylococcus pyogenes*

SEVERAL workers[1-6] have demonstrated recently the inhibitory action of acid extracts of leucocytes towards microbes

Amano[7] *et al* found a cell-free acid extract of guinea pig leucocytes to be lethal to coagulase-negative *Staphylococci*, and to be slightly inhibitory to coagulase-positive *Staphylococci* This active principle they call leucozyme *A* and show that although lysozyme is present it is not the agent responsible for the destruction of the *Staphylococci*

Hirsch[8] has also reported on the destructive activity of an acid extract (phagocytin) of leucocytes obtained from several species This extract is prepared free of lysozyme I have confirmed both these observations using *Staphylococcus albus* and *aureus* and extracts made from guinea pig, rabbit and human leucocytes My work has been extended to compare the activity of human and rabbit phagocytin towards *Staphylococcus pyogenes* obtained from a variety of lesions which exhibit qualitative and quantitative differences in toxin production, I also compared the action of an extract made from leucocytes obtained from patients with acute osteomyelitis with that from healthy donors

It seemed reasonable to expect that *Staphylococcus pyogenes* which have survived phagocytosis and proliferate in the bone marrow would show a greater resistance to phagocytin The results, shown in Table 2, do not support this No significant difference is found in the action of either of the extracts towards *Staphylococci*.

Table 1 REDUCTION IN STAPHYLOCOCCAL COLONY COUNTS BY PHAGOCYTIN

No of strains staphylococcoid *pyogenes*		Human phagocytin extract Col count reduced to		Rabbit phagocytin extract Reduction of from 140 to 10 or less per cu cm
		10 or less per cu cm	10/20 per cu cm	
Nasal	4	4	0	4
Boils	3	1	2	3
Osteomyelitis	30	26	4	30
Miscellaneous	23	16	7	23
Total	60	47	13	60

Average count for untreated controls, 130–140 colonies per cu cm

Table 2

No of strains		Normal human white blood cells extract Col count		Osteomyelitic white blood cells extract	
		10 or less	10–20	10 or less	10–20
Nasal	2	2		2	
Osteomyelitis	8	6	2	6	2
Total	10	8	2	8	2

Average count for untreated controls, 130–140 colonies per cu cm.

The extracts have been made by Hirsch's methods, incubated for 2 hr. with a 4-hr shaken culture of the test organism in broth standardized to give a reading of 1 0 on an EEL colorimeter using an orange filter After incubation this standard extract and suspension is finally diluted to 1/50,000 and pour plates made with 5 ml agar in standard 2-in Petri dishes Controls are set up using distilled water instead of the extract The colonies are counted per cubic centimetre, for the controls the average count is between 130 and 140 per c c

In view of the Japanese report that their acid extract was more inhibitory towards coagulase-negative *Staphylococci*, an attempt was made to see whether a partially purified coagulase preparation gave any protection No difference was noted when this was used The *p*H at which tests were made fell to *p*H 5 6–6 0 (The coagulase was prepared by the late Dr Edward Duthie of Southampton)

Coagulase, α toxin, staphylokinase, leucocidin (some) and hyaluronidase production of the *Staphylococci* were noted, and there is no correlation between the toxigenicity of the *Staphylococci* tested and their susceptibility to phagocytin, or the nature of the lesion from which the organism was originally isolated, the two strains showing greater resistance to the osteomyelitic extract were different from those two relatively resistant to the normal extract Neither is there any apparent relationship between phagocytin susceptibility and the ability to provoke antibody response in the patient to the various antigens of the coccus The morphology of the *Staphylococci* surviving incubation with extracts is normal, as might be expected from the appearance of the colonies

Lathyrogenic Activity *in vitro*

REASONS have already been given for the view that the basic aortic lesion in experimental lathyrism is mainly a failure of formation of elastic tissue[1]. An attempt has since been made to investigate, *in vitro*, the effect of various lathyrogenic substances on the production of elastic fibres.

Explants were taken from the ventricles of chick embryo heart (the great vessels being carefully removed so that the only elastic tissue in the initial explants was the small amount present in the coronary vessels) and were cultured by a modification of the method described by Bloom[2] using Waymouth's medium[3] with 10 per cent calf serum for 10–12 days at 39° C as the fluid phase. Whether the explants were grown in fibrin clot or directly on glass, in stoppered glass tubes or in Petri dishes in an atmosphere with 5 per cent carbon dioxide did not affect the results. Some additional results obtained from experiments with mouse embryo hearts do not differ markedly from those with chick embryo hearts and are not reported in detail here.

A preliminary experiment showed that fibres similar to those described by Bloom[2] first appeared after 7 days incubation, and were well formed after 10 days. Subsequent cultures were therefore examined after this time. The fibres stain with Weigert's method for elastica, with orcein, and with Gomori's aldehyde fuchsin, providing strong presumptive evidence that they are indeed elastica; further investigations are being made into this matter. The fibres usually run parallel to each other to form a circle or arc of a circle around the explant at the junction of the original tissue and the monolayer extending from it. They appear to have formed immediately under the surface layer of cells at the farthest point from the glass. In a few cases, particularly in small explants, the fibres form a disorganized network, or may show some radial orientation. In the presence of lathyrogenic substances these fibres were not found.

For assay of lathyrogenic activity each experiment comprised multiple cultures and graded concentrations of test substances. Only those experiments in which one or more control cultures produced elastica were considered. In successful cultures 40 out of 51 (78 per cent) of the controls produced elastica. When β-aminopropionitrile hydrochloride—known to be lathyrogenic *in vivo*—was added to the cultures it was found that a concentration of 2 mgm/ml killed the majority of the explants, and in the few cases where the cells survived elastic fibres were never formed. With lower concentrations down to 80 μgm/ml, although the explants were healthy as frequently as in the control cultures, elastic fibres were never formed. With still lower concentrations the percentages of healthy cultures producing elastic fibres were as follows: 16 μgm/ml, 10 per cent; 3·2 μgm/ml, 12·5 per cent; 0·64 μgm/ml, 66 per cent. Two other compounds active *in vivo*, β-mercaptoethylamine[4] and semicarbazide[5], inhibited the formation of elastic fibres at concentrations of 3·4 μgm/ml and 0·66 μgm/ml respectively. Sodium propionate and *n*-propylamine, both inactive *in vivo*, were also inactive *in vitro* at concentrations of up to 364 μgm/ml and 0·16 per cent respectively; higher concentrations caused cell death. Assuming uniform distribution of lathyrogenic substances throughout animal tissue, the doses of β-aminopropionitrile hydrochloride, β-mercaptoethylamine and semicarbazide which inhibit the formation of elastica *in vitro* correspond to the concentrations calculated as being present in the tissues of mice treated with these compounds and showing rupture of the aorta. The results demonstrate that lathyrogenic substances act at a cellular level, and the parallelism between the *in vivo* and *in vitro* findings supports the original hypothesis that the aortic rupture in experimental lathyrism is secondary to a failure of formation of normal elastic tissue.

An Early Test for Possible Skin Carcinogens

IN previous papers[1–4] it has been shown that it is possible by a tetrazolium reduction method to estimate changes in the rate of formazan deposition in the epidermis of hairless mice after different skin irritants.

A characteristic reaction was observed after the application of some carcinogenic substances and after local irradiation with X-rays. The topical application of carcinogens produced a short initial rise in formazan deposition, followed by a depression of longer duration. An initial decrease in formazan deposition was observed after the application of some non-carcinogenic compounds. It was suggested that an initial rise in formazan deposition might be specific for skin irritants with carcinogenic potency.

Examining the validity of this hypothesis, a blind-test with 20 different compounds was performed. The substances were dissolved in benzene and the different samples were indicated by *A*, *B*, *C*, ... etc.

Hairless mice, 8 males and 8 females for each test substance, were given 0·005 ml. of the solution as a single, topical application to a circumscribed area of the skin. The formazan deposition per mgm dry epidermis per hour measured on the first and the second day after the application was recorded. It was postulated that mean relative values of 1·100 and above should indicate a compound with skin carcinogenic potency.

The results of the blind test are given in Table 1. The values are arranged in order from the lowest to the highest. To the right is presented the list of answers, including an indication of the carcinogenic potency of the substances. In this communication only those substances are listed as complete carcinogens which each alone are known to produce epidermoid carcinomas in mouse skin after topical application.

It appears that there is a correlation between such complete carcinogenic activity and initial rise in formazan deposition. The above-mentioned hypothesis is thus given some further support and the method may probably be used as an early test for possible skin carcinogens. It must, however, be kept in mind that correlation never proves specificity.

P	1.010	0.08	1,2,3,4 dibenzanthracene	–
O	1.307	0.12	4 nitroquinoline N oxide	+
C	1.337	0.11	Croton oil	+
N	1.405	0.12	9,10 dimethyl 1,2 benzanthracene	+
A	1.408	0.08	3,4 benzpyrene	+
R	1.410	0.09	3 methylcholanthrene	+
M	1.634	0.12	1,2,5,6 dibenzanthracene	+

The substance *P* (1,2,3.4 dibenzanthracene), for which a borderline value (1.010) was observed, is the substance that represents an exception in the interesting observations of Heidelberger[5] concerning binding of carcinogens to skin proteins.

There is no general agreement as to what tetrazolium really measures. It acts as an electron acceptor and is thereby reduced to formazan. The amount of formazan deposited per mgm dry epidermis per hour may probably be considered as an estimate of the activity of the energy-generating processes in the cell, mainly the mitochondrial enzyme systems. Increased values may mean some injury to the mitochondria, for example increased permeability of the mitochondrial membrane.

PALÆONTOLOGY

A Mammalian Fauna from the Kimmeridgian of Portugal

A MAMMALIAN fauna, consisting of 14 specimens, has been collected from the small Guimarota coal pit, near Leira. The age has been determined as Kimmeridgian by means of the ostracods and characeans. The pit is still in operation and it seems possible to obtain a good fauna, qualitatively as well as quantitatively. A typical coal swamp fauna has been encountered. Lamellibranchs, gastropods, and ostracods are frequently found, the holostean genus *Lepidotus* is well represented by scales. Carapace fragments of turtles are less frequently found. Crocodiles predominate numerically, with many shed teeth and scutes. Many lizard jaws have been collected, as well as a few shed teeth of dinosaurs.

The fauna contains the earliest known multituberculates (two good jaws without molars and one skull without teeth) and the oldest pantotherian upper dentition. The latter has a tooth formula of P^4/M^5 (P^{2-4} have been lost, P^4 prior to fossilization). There is also a good pantotherian lower jaw which has a tooth formula of $I/C_1/P_4/M_8$. All the molars are unbasined, the trigonid being open lingually. The talonid is covered by the paraconid of the tooth behind, it is not worn by the opposing lingual cusp of the upper molars. The lower molars have their longitudinal axis oblique to the axis of the jaw.

The molars are shorter than those of *Amphitherium* and the talonid is much smaller than in the latter tooth. The metaconid almost equals the protoconid in height and is higher than the paraconid. This is a feature which is found also in the dryolestid genera *Dryolestes*, *Laolestes*, *Phascolestes* and *Peramuspalax* as well as in the paurodont genera *Archaeotrigon* and *Tathiodon*. The tooth formula of the present jaw is now diagnostic in respect to differentiation between Amphitheriidae and Dryolestidae, but it excludes paurodont relationship.

The right lower, M_3, and right upper, M^3, of the pantothere are shown in Figs 1 and 2. There is no suggestion that these upper and lower jaws belong to the same genus. The tooth shown in Fig 2 is typical as regards number of cusps on all teeth. M^{1-3} are longer than broad, M^4 and M^5 are broader than long. The tooth is similar in many respects to *Herpetairus arcuatus* from the Morrison formation. Both have the same number of cusps of equal relative height. A large basin is formed by five of six cusps, two buccally, two posteriorly and one, the highest, lingually. The sixth cusp, at the anterobuccal corner, stands outside

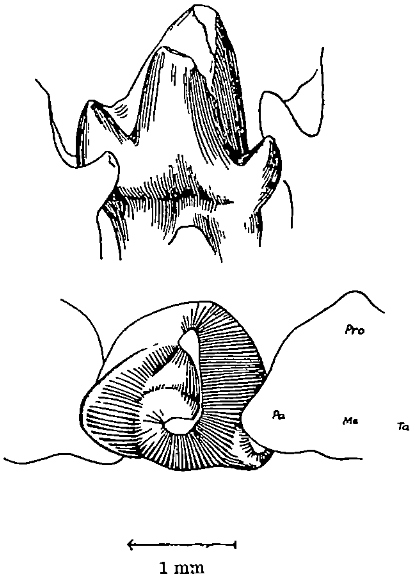

Fig 1 Right lower M_3 of Kimmeridgian pantothere

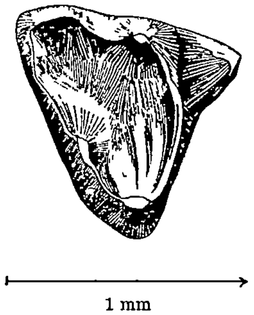

Fig 2 Right upper M^3 of Kimmeridgian pantothere

the triangular basin and dorsal to it The function of this cusp is to buttress the posterobuccal corner of the tooth in front , similarly the talonid cusp buttresses the paroconid The second highest cusp, as in *Melanodon, Herpetairus, Amblotherium* and *Kurtodon,* stands at the anterobuccal corner of the basin

Primitive features of the lower jaw and maxilla, seeing that they are older than Purbeckian, are: (1) in the jaw there is an open, not a closed trigonid (the Purbeckian paurodontids with an open trigonid are similar to the Bathonian *Amphitherium* in this respect), it is agreed that in *Amphitherium*, the earliest known pantothere, the open trigonid is a primitive character which the paurodonts retain, (2) it has been postulated that in pantotherian upper molars of pre-Purbeckian age the length would equal the width in all teeth In the Kimmeridgian upper dentition now available, M^{1-3} are longer than broad, whereas in the Purbeckian only M^1 has such dimensions

It has been customary to discuss the origin of the Pantotheria whenever a new mammalian fauna in the Mesozoic is discovered Such procedure is inevitable, taking into consideration the few faunas known and the interest that the Pantotheria arouse as ancestors of the placentals and marsupials I do not agree with a derivation of Pantotheria from Rhætic symmetrodonts, as Butler[1], Kermack and Mussett[2], and Patterson[3] do I consider a derivation from Rhætic triconodonts more likely The new maxillary dentition does not provide any new item of symmetrodont affinity The second largest cusp (Butler's buccal cusp, Patterson's stylocone) stands right in the middle of the buccal side as in Purbeckian teeth, forming a tricuspid front with the cusp at the anterobuccal corner (Butler's anterior cusp, Patterson's parastyle) and the cusp at the postero-buccal corner (Butler's posterior cusp, Patterson's "metastyle") Patterson's cusp on the anterior crest of some Purbeckian dryolestids, said to indicate symmetrodont affinity, is not present on any of the molars of the Kimmeridgian maxilla The central buccal cusp has in the new maxilla the same relative height as in the Purbeckian teeth, while if it were to be a homologue of the anterobuccal cusp of the Symmetrodonta, one would expect it to be less high

The morphological break between upper premolar and molar is considerable in the dryolestid upper dentition Only the aberrant *Docodon* has a P^4 which is so similar to the M^1 that the nature of the paracone and protocone in the molars of this genus has never been debated The paracone stands in the middle of the buccal row of cusps, flanked by two smaller cusps, the protocone is a lingual neomorph, added to an original triconodont pattern

I believe that *Docodon* and all other Pantotheria have—as Simpson[4] originally claimed—the same cusp pattern and the same origin. A history of all cusps of the Albian therian from Texas, of the Purbeckian maxilla, of the new Kimmeridgian maxilla and the Rhætic triconodonts or symmetrodonts can be written irrespective of whether one begins with a triconodont or a symmetrodont With a triconodont at the base a much simpler history of all dental elements concerned is possible Moreover, this would solve the *Docodon* paradox, namely, that one genus which is patently neither triconodont nor symmetrodont has a different origin from all (other) Pantotheria

As regards jaws as well as teeth, the Purbeckian *Docodon* was a living fossil, giving a hint of what happened to the still unknown triconodonts which, in the Upper Liassic, embarked on the road to the Pantotheria

Chitinozoa from the Ordovician Nod Glas Formation of Merioneth

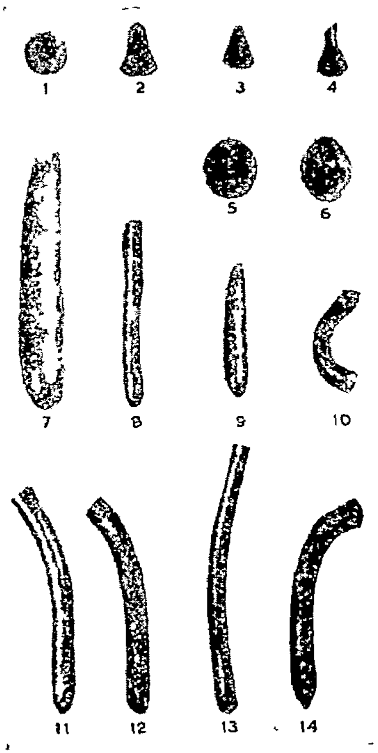
CHITINOZOA[1] are microscopic, flask-like fossils of problematical affinities They are generally black, structureless and opaque, being composed of 'pseudochitin', and ranging from 0 03 mm to 1 5 mm in length They are bilaterally symmetrical and may be club-like, rod-like, or globular in form, the test being thin, hollow and open at one end The surface of the test is usually smooth, but is sometimes tuberculate Spines may be present and aggregates of up to six individuals have been recorded[2].

The zoological affinities of the Chitinozoa have been discussed by Collinson and Schwalb[2], who conclude that they represent an extinct order of rhizopod protozoans

Chitinozoa are known from strata ranging from Ordovician to Devonian in age from Germany, France, Czechoslovakia, the United States, Canada and Brazil The only previous record of Chitinozoa from Britain is that of Lewis[3], who described two species of *Conochitina* (C cf *C filifera* Eisenack and *C cactacea* Eisenack) in thin sections of the Upper Carodocian "Phosphate band" of Pen-y-garnedd, Montgomeryshire

The present specimens were collected from crags on the face of the Graig Tynant (M R SH/898218), about two miles north of Llanmawddy, Merionethshire[4] They occur in limestone nodules 15 ft above the base of the Nod Glas Formation[4], and were extracted by digestion of the limestone in acetic acid.

The Nod Glas chitinozoa fall into three well-defined morphological groups The most common are elongated tubular forms, with the oral end open and the aboral end roundly closed Most of these (for example, Fig 8) are straight and agree broadly with Eisenack's description of *Rhabdochitina magna* Eisenack, although they show rather more variation in the form of the distal end than is recorded by Eisenack Numerous other specimens show, however that there is a complete gradation between such forms and those with a gently or strongly curved axis (Figs. 11–14) and also between forms which have a uniform diameter along their entire length (that is, 'tubular' forms) and those in which the aboral diameter is rather larger than the oral (that is, 'club-shaped' forms) Such forms as the latter have been referred to the genus *Conochitina* Eisenack, but the present specimens suggest that it is difficult to separate these from 'typical' members of the genus *Rhabdochitina* The axial curvature does not seem sufficient to exclude most of these forms from the species *R magna* A precedent for the evaluation of such variation as infra-specific is provided by Eisenack[5],



Figs 1–14 Chitinozoa from the Ordovician Nod Glas Formation of Merioneth (× c 44)

1–4, *Illichitina* cf *I campanulaeformis* (Eisenack) 1, oral view of specimen, showing cross-section of cylindrical neck and basal outline of chamber, 2–4, oblique lateral views of specimens showing general form of chamber

5–6, *Lagenochitina*? sp Lateral views showing general form 7 and 9, Club-shaped forms of *Rhabdochitina* (*Conochitina* of some authors)

8, 11–14, *Rhabdochitina* spp lateral views of specimens showing variation in general form of chamber

10, fragmentary specimen Gen et sp indet

who included various forms showing comparable variation within the species *Rhabdochitina taenia* Eisenack

The second group of chitinozoa are bell-shaped forms (Figs 1–4) which closely resemble the species *Illichitina campanulaeformis* (Eisenack) The base is often perforated, and they appear to show morphological variation which partly bridges the gap between that species and *I crotalum* Collinson and Schwalb

The third group are globular forms (Figs 5 and 6), which may represent the genus *Lagenochitina* Eisenack Some have an invaginated opening, but all appear to lack the tubular neck which is characteristic of most members of the genus

I am most grateful to Prof Harry B Whittington, of Harvard University, who accompanied me in the field, and to Mrs Shirley Osborn, who has given me considerable help in the extraction of specimens

BIOLOGY

Growth-stimulating Activity of *Trans*-Caffeic Acid isolated from *Coleus rhenaltianus*

In our previous work[1] on the abscission of debladed petioles of *Coleus rhenaltianus*, we met with an auxin that was not an indole derivative, in ether extracts from the leaves

On paper chromatograms of ethanolic leaf and stem extracts, developed with isopropanol/water (5 1 v/v), we now find two blue fluorescent spots (R_F 0 84 and 0 79), the eluates from which both enhance the elongation growth of *Avena* coleoptile sections (Table 1)

Table 1 Growth-rate of 3 mm *Avena* Coleoptile Sections in a Solution of 1 per cent Glucose and the Eluate from a Chromatogram (Spots at R_F 0 79 and 0 84) of an Ethanolic Leaf and Stem Extract of *Coleus* Growth recorded after 24 hr Number of Sections between Brackets

Increase in length (eye-piece micrometer units)			
Spots at R_F 0 79		Spots at R_F 0 84	
Control	Diluted eluate	Control	Diluted eluate
16 8 ± 1 59 (15)	26 8 ± 1 50 (14)	13 0 ± 0 72 (15)	19 4 ± 0 76 (17)
16 6 ± 1 34 (13)	26 2 ± 1 73 (14)	8 4 ± 0 89 (10)	20 4 ± 1 04 (10)
8 4 ± 0 89 (10)	23 9 ± 1 86 (9)	5 0 ± 0 45 (10)	10 8 ± 0 58 (10)

The eluates show practically the same ultra-violet absorption spectrum as the auxin found earlier in ether extracts of leaves The substance at R_F 0 84 was identified by us as *trans*-caffeic acid Most probably the substance at R_F 0 79 is a closely related one, since it gives several identical colour reactions and, after treatment with diluted sulphuric acid, is transformed into *trans*-caffeic acid, with R_F 0 84 It is neither chlorogenic nor *cis*-caffeic acid Both compounds are precipitated with neutral lead acetate, after removal of the lead from the yellow precipitate, growth activity in the coleoptile section test is unimpaired.

Generally the cinnamic acid derivatives caffeic and ferulic acid are considered to be growth inhibitors[2] Other reports mention a synergistic action of these substances with the growth regulators indole-3- and α-naphthyl-acetic acid[3,4] Caffeic acid alone is thought not to exert any true auxin activity We find, however, that commercial *trans*-caffeic acid, at a concentration of about 1 μgm /ml or less, greatly enhances the elongation growth of coleoptile sections (Table 2), about as much as does indole-3-acetic acid in these circumstances.

Table 2 Growth-rate of 2 mm *Avena* Coleoptile Sections in Solutions of *trans*-Caffeic Acid and Indole-3-acetic Acid in Distilled Water Both Substances were added 6 hr after cutting the Sections Growth has been recorded after 18 hr Number of Sections between Brackets

Increase in length (eye-piece micrometer units)					
trans-Caffeic acid			Indole-3-acetic acid		
Control	1 μgm /ml	0 5 μgm /ml	Control	1 μgm /ml	0 5 μgm /ml
3 8±0 45 (16)	5 7±0 35 (21)	4 3±0 34 (18)	3 0±0 48 (17)	5 0±0 82 (17)	4 8±0 60 (10)
1 2±0 28 (14)	5 0±0 34 (14)	3 7±0 27 (18)	1 5±0 54 (10)	3 0±0 59 (10)	3 2±0 46 (11)
2 2±0 42 (15)	5 6±0 34 (15)	4 4±0 44 (13)	2 4±0 34 (14)	5 5±0 54 (14)	4 6±0 58 (14)

The rather general occurrence[5] of caffeic acid in plant tissues thus suggests that this substance may be a very important natural growth regulator, not less important than indole-3-acetic acid

Of both stereo-isomeric cinnamic acids, only the *cis*-isomer is physiologically active in growth[6] Our own experiments have confirmed once more the inactivity of *trans*-cinnamic acid The *cis* configuration has been supposed to be generally important in growth regulation It is believed, moreover[7], that the introduction into the lipophilic aromatic nucleus of ydrophilic substituents results in the formation of nactive or weakly active compounds Taking into ccount these structural requirements, we should not t all expect auxin activity in *trans*-caffeic acid, which is 3′,4′-dihydroxy cinnamic acid The extreme difference in growth activity between *trans*-cinnamic and *trans*-caffeic acid on the contrary seems to indicate a special importance of the ortho-diphenol configuration in growth regulation

Our results stress the importance of a thorough study of the physiological function of cinnamic acid derivatives in growth and metabolism

High Root-Pressures in Palms

Despite some impressive demonstrations of root-pressure[1-3], 'pumping' or positive pressure is generally thought to be of little importance for the ascent of sap in trees This is probably true for dicotyledons, but in ten species of palms at Calcutta I was able to detect and measure positive root-pressures throughout the year, sometimes enough to lift sap to heights exceeding those of the trees

A palm has rather uniform adventitious roots growing from the bole, or stem base The number at bearing stage varies from a few hundred to more than 13,000 as in *Cocos nucifera* Such a root, generally about 0·7 cm in diameter, is cut about a metre from the bole The proximal end, attached to the tree, is connected by a long rubber tube to a glass tube of 3 mm bore dipped in water, and connexions sealed with paraffin The distal end, severed from the tree, is connected by a short rubber tube either to a vertical glass capillary tube or a mercury manometer

The maximum suction, or negative pressure, is usually reached within 10 hr, and may persist for as long as four months Its value fluctuates rapidly with atmospheric changes, as would be expected if transpiration were an important cause of it The positive pressure usually starts developing after about 24 hr, and reaches a maximum after 10–20 days, the time varying between species and between roots of the same tree After a day or two it begins to decline, and disappears after about two months There are slight diurnal fluctuations, the pressure being higher by day. Table 1 gives data on 51 palm and 2 banana (*Musa sapientum*) trees The roots of *Phoenix sylvestris* are not suitable for the operation described, and the low values obtained are probably due to leakage In seven of the eleven species, the positive pressure exceeds the negative pressure considerably It often exceeds the plant's needs. Thus a seedling of *Borassus flabellifer*, a little under a metre high, had a root which developed a pressure of 5·24 m of sap Again, in *Musa sapientum*, the only monocotyledon other than a palm which I studied, and which behaves just like the palms, the suckers die before reaching a height of 4 m

In order to demonstrate that my results are due to a physiological property of palms, and not to differences of method, I used just the same methods on

Table 1

Species of trees studied	Number	No of roots connected for		No of roots showing		Maximum height (cm) of water column	
		Suction pressure	Pumping pressure	Suction	Pumping	Sucked	Pumped

Total	5	25	25	24	nil		
Cycas circinalis	1	7	7	5	nil	35 7	0

five dicotyledonous trees and one gymnosperm The results are given in Table 2, and require no comment

It seems likely that monocotyledonous plants, having no secondary growth, behave very differently from dicotyledons As M H Zimmermann (private communication) says "because most monocots do not form new vascular tissue in the lower part of the trunk as dicots do, a cohesion mechanism alone would run into difficulties" The method is clearly important as others[4-6] have failed to demonstrate root pressure in palms

A few simple experiments suggest that the observed root pressures suffice to drive sap up the stem about as easily as up a capillary tube The distal part of a cut root of a fruited banana plant was seen to develop pressure The plant was decapitated at 2 25 m above ground-level, and the cut root reconnected with a rubber tube Other agencies such as transpiration are probably less important than root pressure.

Probable Mechanism of Resistance of Varieties of Cocoa to Black Pod Disease caused by *Phytophthora palmivora* (Butl.) Butl.

Isolates of *Phytophthora palmivora* showed different degrees of pathogenic activity (measured by rate of spread of lesions at 25° C) when wound-inoculated into surface-sterilized pods of particular varieties of cocoa (*Theobroma cacao*, L) One isolate, *WA* 8, failed to attack any variety Isolates also showed varied rates of spread in different varieties of cocoa The variety *SCA* 6 was consistently more resistant than the variety *ICS* 1. Holliday[1] has shown that the variety *SCA* 6 is more resistant to artificial inoculation of intact pods with a zoospore suspension than is the variety *ICS* 1

Rotted cocoa pod tissue showed no evidence of pectolytic enzyme activity when tested by Brown's maceration method[2], and by the polygalacturonase agar plate method[3] The same tests, however, showed that pectolytic enzymes were produced by *Phytophthora palmivora* on autoclaved potato blocks

Aqueous extracts of host tissue, prepared by homogenization of tissue in distilled water (during which browning occurred), when added to pectolytic enzymes of *P palmivora* from invaded autoclaved potato blocks caused inhibition of the pectolytic enzyme activity The inactivating ability of such extracts was removed by pre-treatment with 0 5 per cent aqueous solution of gelatin If the homogenization was carried out in 0 1 per cent aqueous sodium dithionite solution browning did not occur and the extracts did not cause inhibition of pectolytic enzyme activity These results suggested that the inhibition was due to high molecular weight tannins produced by polymerization of the products of oxidation of host polyphenols by polyphenol oxidase[4-7]

Tests of macerating activity of pectolytic enzyme of *P palmivora* on cocoa pod tissue showed tha tissue disks were more resistant to maceration whe allowed to brown after cutting than if browning wer prevented by immersion in a 0 1 per cent sodiu dithionite solution Moreover, disks of the mor resistant variety *SCA* 6 browned more rapidly tha those of the susceptible variety *ICS* 1 and showe correspondingly greater resistance to maceration

If the resistance of cocoa varieties to rotting b isolate *WA* 8 were due to the inactivation of pectolyti enzymes of the fungus by action of the host polyphenol oxidase system, then reduction of the activity of the latter system by low oxygen tension would be expected to break down this resistance Some of these effects have been demonstrated Cocoa pods o variety *IMC* 67 were wound-inoculated with the avirulent isolate *WA* 8, placed at 60, 21 and 2 per cent oxygen tension and incubated at 25° C Lesions were produced at 2 per cent oxygen tension but were very light brown in colour, whereas at oxygen tensions of 21 and 60 per cent no lesions were produced, the only reaction being a narrow dark margin around the point of inoculation

Pods inoculated with isolate *WA* 8 and incubated at 15° C produced lesions, whereas no attack occurred at 25° C or 30° C Low temperature also might be expected to reduce the polyphenol oxidase activity and this reduction in host resistance would explain the better growth of the fungus in the host tissue at low temperatures than at temperatures nearer the optimum for growth of the fungus on agar culture

A virulent isolate produced lesions at 60, 21 and 4 per cent oxygen tensions; size of lesions increased from an average diameter of 2 1 cm at 60 per cent, to 3 3 cm at 21 per cent and 4 5 cm at 4 per cent after three days incubation at 30° C The lesions varied from dark brown at 60 per cent, to brown at 21 per cent and lighter brown at 4 per cent, indicating a correlation between rate of attack and browning of host tissues

Tests of growth-rates of *P palmivora* at various temperatures and oxygen tensions showed that the results could not have been solely due to direct effects on the growth-rate of the parasite Other host factors would be affected by alteration of oxygen tension and temperature, but an alteration of the balance between the pectolytic enzyme systems of the parasite and the polyphenol oxidase system of the host offers the simplest explanation of promotion of attack by low oxygen tension and low temperature

If resistance is correlated with polyphenol oxidase activity of cocoa pod tissue it may be possible to select varieties with high activity of the polyphenol oxidase system, and if, as would be expected, these show some degree of resistance, to use them in breeding resistant varieties

It is hoped that a fuller account of this work will be submitted for publication shortly

Canadian Salmon caught off Greenland

On October 10, 1960, an Atlantic salmon 71 cm total length, weighing 3 7 kgm (8 2 lb), and carrying Fisheries Research Board of Canada tag No 1,616, was caught in the sea off Tassiussaq (65° 06′ N , 52° 08′ W), near Napossok to the south of Sukkertoppen, Greenland The fish was tagged on May 22, 1959, in the estuary of the Miramichi River near Chatham, New Brunswick (47° 04′ N , 65° 28′ W), as a smolt 17 5 cm in total length It was one of 3,500 smolts tagged there in May and June, 1959, with tags patterned after those used by Dr Borje Carlin[1] in Sweden, but had printed laminated plastic pendants supplied by a commercial firm

Scales from the recaptured fish show three years of river life typical of Miramichi River smolts, followed by a first sea year of moderate growth and a relatively wide winter band The second sea year includes a period of fast growth followed by a summer check, then a period of fast growth continuing to the time of capture in October

This recapture represents the longest migration yet recorded, about 1,500 miles, for Canadian Atlantic salmon the river of origin of which is known through fin-clipping or tagging Many fin-clipped salmon from Quebec, New Brunswick, and Nova Scotia rivers have been recaptured, however, in sea fisheries as far away as Newfoundland and Labrador The recapture also lends some support to the suggestion[2] that salmon from both sides of the North Atlantic share common feeding grounds The first direct evidence of Scottish salmon reaching Greenland waters was provided by the recapture in October 1956 near Sukkertoppen, Greenland, of a fish tagged as a kelt in November 1955 at Loch na Croic, Ross-shire[3]

We are indebted to Dr Jørgen Nielsen, of the Ministeriet for Grønland, for details of this recapture accompanied by a scale sample, and to Dr P F Elson, of the Biological Station, St. Andrews, New Brunswick, for reading the scales

Penetration of Spines from a Marine Diatom into the Gill Tissue of Lingcod (*Ophiodon elongatus*)

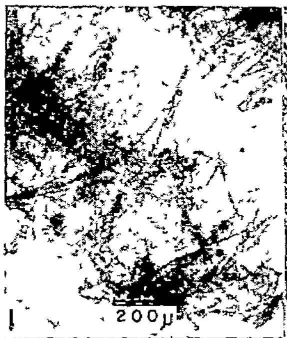

Fig 1 *Chaetoceros* cells and setæ on surface of lingcod gill filaments Specimen had died in live-well within 8 hr of sampling

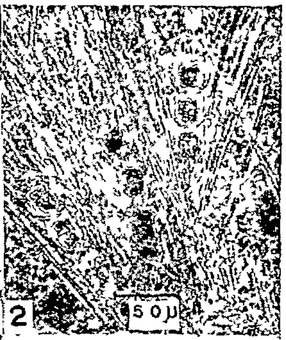

Fig 2 Phase contrast view of *Chaetoceros* sp and setæ on gill mucus Same specimen as in Fig 1

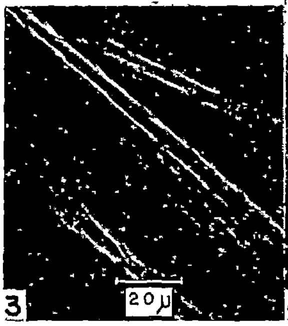

Fig 3 Dark field picture of *Chaetoceros* setæ showing apically directed barbs

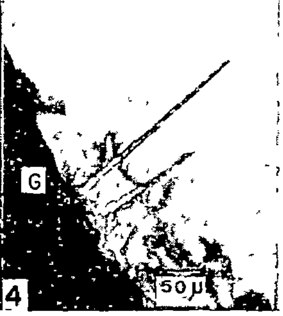

Fig 4 Setæ embedded in gill of dead lingcod which had been exposed for 24 hr at 11° C to 1–5 × 10^5 *Chaetoceros* cells/l *G* indicates gill tissue

Fishermen from the Porlier Pass area of Vancouver Island were experiencing unusually high mortalities among lingcod (*Ophiodon elongatus*), which according to common practice were being held in surface live-wells prior to the weekly slaughtering and transport to market Examination of dead and dying fish showed only that all specimens had discoloured gills with considerable detritus embedded in the gill mucus (Fig 1) Much of this detritus was composed of *Chaetoceros convolutus*, one of a common group of marine plankton diatoms[1], and their siliceous spines (Fig 2) The spines or setæ with their apically directed barbs are shown in Fig 3 These findings suggested the possibility that the setæ might bring about tissue damage and be a direct or indirect cause of death. Gill tissue is particularly vulnerable to injury from chemical and biotic agents because of its intimate contact with the external environment and because of its delicate structure It was therefore decided to expose apparently healthy lingcod (18 in) to 3–4 times the natural concentration (that is, 1–5 × 10^5 cells/l) of *Chaetoceros* while the fish were held in aquaria. Control fish were kept in natural sea water

Only one of the three treated fish died, from undetermined causes, and although the final results were inconclusive, it is of considerable interest that setæ were found embedded in the gill tissue of the dead fish (Fig 4) It was established that the spines had actually penetrated the tissue and were not merely trapped in the mucus The incidence and extent of the penetration were not determined, but four embedded setæ were seen in an area of a few square millimetres The only comparable record appears to be that of Wood and Yasutake[2], who found that ingested 'hairs' from the lepidopterous larva *Halisidota argentata* penetrated the stomach and visceral organs of fingerling salmon by working their way inwards and thus causing extensive damage to the tissues The insect hairs, like the algal setæ, have apically directed barbs and therefore both shafts must enter butt first for maximum penetration This direction of entry into lingcod gill tissue is shown in Fig 4 Setæ which are entrapped on or embedded in the gills might cause death by capillary hæmorrhage, by anoxia from the stimulation of heavy mucus secretion or by debilitation of the tissue allowing microbial invasion

It is not yet possible to say whether this penetration is only a laboratory oddity or whether it is also a significant natural phenomenon, but the subject appears to warrant further investigation by marine biologists

I am very grateful to Dr T. Parsons of the Pacific Oceanographic Group for his valuable advice and assistance

An Intra-Pericardial Hepatic Intrusion in the Common Dogfish

MISS BARBARA STEVENS, of Brooklands Technical College, has been kind enough to send me a dogfish (*Scyliorhinus canicula*) with an intra-pericardial hepatic intrusion Only the anterior end of the dogfish is available, but the length from the tip of the snout to the anterior insertion of the pectoral fin is 9 cm, and the anterior ends of the testes present a mature appearance Thus it may be inferred that the dogfish had practically reached full size with this abnormality when it was caught

The septum transversum is perforated on the right side only, and the hepatic intrusion is remarkable for its extent (Fig 1) On the right side the liver extends through the pericardial cavity for a distance of 18 mm, almost reaching the anterior end of the conus arteriosus Laterally, the liver extends 23 mm, reaching across almost the entire width of the pericardial cavity at its posterior end The heart appears to be normal, except that the ventricle is displaced slightly forward and to the left

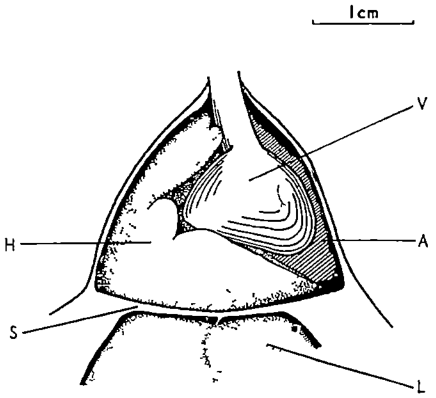

Fig 1 Hepatic intrusion in the pericardial cavity of a dogfish *A*, Auricle, *H*, hepatic intrusion, *L*, liver, *S*, septum transversum, *V*, ventricle

The volume of the intra-pericardial intrusion was estimated by making a 'Plasticine' replica and measuring the volume of this by displacement This was found to be 2 7 c c Similarly, the volume of the heart was found to be 2 2 c c Thus the hepatic intrusion occupied rather more of the pericardial cavity than the heart The volumes of the hearts of a small number of dogfish under class dissection were also estimated by making 'Plasticine' models, and then the volumes of the actual hearts were determined by displacement after excision The method, as performed by students, was found subject to an error of not more than 20 per cent The volumes of the pericardial cavities of the normal animals were also found by making 'Plasticine' casts of the cavities after excision of the hearts From these results it appears that the volumes of the heart and of the pericardial cavity of the abnormal animal are within the range to be expected, and that often the heart occupies only about half the volume of the pericardial cavity

In the development of craniates, the pericardial cavity is first delineated from the perivisceral cœlum by the mesocardia At this stage the pericardial cœlom is still in contact with the perivisceral cœlom by the dorsal and ventral parietal recesses of His Afterwards the primary septum transversum is formed by proliferation of connective tissue on the anterior face of the developing liver[1] It must be presumed that in this animal the liver rudiment initially developed asymmetrically in such a way that the aperture ventral to the right mesocardium was not occluded by connective tissue on the anterior face of the liver rudiment Thus the abnormality represents a patent right ventral parietal recess of His Goodrich[2] has shown that in *Scyliorhinus canicula* the dorsal apertures remain as a forked pericardio-peritoneal canal The anterior end of this canal was clearly visible in the abnormal animal, although the forked posterior ends could not be traced

Shoaling Behaviour in a Mysid

Mysidium columbiae (Zimmer) is common in shallow water in Kingston Harbour, Jamaica It is found during the day in shoals close to the mangroves, usually but not exclusively in the shade of the trees The shoals can be seen swimming horizontally a few centimetres below the surface of the water in a manner similar to shoals of small fish, for which indeed they were at first mistaken The behaviour of *Mysidium* proves to be a combination of fixed responses to external stimuli and social responses by which the shoals are built up and maintained

A number of *Mysidium* placed in a large vessel of sea-water will form a shoal in a few minutes and swim around with their bodies oriented parallel with each other at a constant distance apart Small shoals tend to join larger ones and *Mysidium* separated from the main shoal by a sheet of glass attempt to swim through the glass to join the shoal provided the latter is close enough for them to see it The critical distance for shoaling by visual orientation is about 4 cm at 150 ft-candles illumination *Mysidium* placed in a circular dish 18 cm in diameter illuminated from above swim in one direction around it, keeping station with each other so that all those along a given radius tend to complete a circuit in the same time, those near the circumference swimming several times faster than those near the centre The speed of swimming is photokinetically controlled, being proportional to the logarithm of the light intensity over a range of at least two logarithmic units of illumination At very high intensities swimming tend to be inhibited and the mysids sink to the bottom, while in very dim light the shoal breaks up Removal of both eyes abolishes both the photokinetic response and the ability to swim in a shoal Some astonishingly high swimming speeds have been recorded in these experiments up to 15 4 cm /sec , which is equivalent to about twenty times the animal's length in a second

Light-adapted *Mysidium* are positively phototactic and swim towards a source of light Dark-adapted ones, however, always swim to the bottom of the tank when illuminated irrespective of the position of the light After removal of the pair of statocysts situated in the uropods they always swim away from a light source, to the surface when illuminated from below and to the bottom when illuminated from above

The behaviour of *Mysidium columbiae* is remarkable in several respects Unlike most mysids it is a 'bright-light' animal living close to the water surface under the noonday tropical sun, while in its shoaling behaviour it shows a precision and co-ordination of locomotion comparable with that seen in fish In some respects, however, the social responses of *Mysidium* are not so well developed as in shoaling species of fish Two or more fish will form a shoal instantly but small numbers of mysids will not It seems that critical density or number of animals is required before they will form shoals, which then build up rather slowly, taking from 30 sec to 5 min to become well developed Also a proportion estimated at about 5 per cent do not join the shoals, but swim freely in other directions or remain motionless on the bottom *Mysidium* is more suitable than fish in some ways for an experimental study of shoaling, since it shows no apparent capacity to modify its behaviour as a result of experience

Evidence for a Sexual Phase in the Life-Cycle of an Amœba

THE amœba have generally been thought to be devoid of a sexual phase in their life-history[1], though one earlier report[2], and a recent one[3], indicate a cycle involving fusion of flagellated gametes This communication concerns evidence for sexuality in a diphasic amœba

A flagellate ascribable to the genus *Heteramœba* and very near *H globosa* Skuja[4] is a widespread, though by no means common, inhabitant of brackish supra-littoral rock pools This organism, referred to here as *Heterochromonas clara* nom prov , differs from *H globosa* in being larger (30µ diam) and in not having contractile vacuoles, but, like *H globosa*, it has no stigma It was abundant in August 1960 in the polluted pools at the base of the cliff below the large gannetry on Ailsa Craig, where it was feeding voraciously on green flagellates Two dozen bacteria-free clones were isolated from this source using a strain of *Brachiomonas submarina* for food One clone was set aside for nutritional work and the remainder were maintained in composite culture for reference The amœbæ first appeared in the latter culture They were unexpected since *Heterochomonas* is not recorded as being the stage in the life-cycle of an amœba, moreover, an isolate of *H clara* from a similar habitat in Finland had been kept for ten years without sign of amœbæ

Several of the amœbæ were isolated and washed singly and used to start cultures Without exception every one of these cultures quickly gave rise to flagellates Twenty flagellated cells were similarly isolated from one of the amœba isolates (145), the ensuing clones being designated 145/*a*–*t* Amœbæ appeared in several of these within a few days, but others have given rise to no amœbæ after four months of maintenance The latter, six in number, were then crossed with each other, that is, mixed in subculture two at a time in all combinations, for it seemed that the flagellate/amœba transformation might, in contrast to other diphasic amœbæ, be under genetic rather than environmental control So indeed it proved, for with certain combinations amœbæ appeared within 24 hr. of the operation, while with others, and in the six parent clones, the populations remained uniformly flagellate (Table 1) Furthermore, the pattern of amœba-formation is consistent with the existence of two mating types among the clones, all of which, it will be recalled, are descended from the same amœba cell This result is taken as indirect, though conclusive proof of a sexual phase in the life-cycle of this organism

Table 1 PATTERN OF AMŒBA-FORMATION IN BI-CLONAL CULTURES

Clone	145*d*	145*k*	145*r*	145*f*	145*i*	145*n*
145*d*	—	—	—	*A*	*A*	*A*
145*k*	—	—	—	*A*	*A*	*A*
145*r*	—	—	—	*A*	*A*	*A*
145*f*	*A*	*A*	*A*	—	—	—
145*i*	*A*	*A*	*A*	—	—	—
145*n*	*A*	*A*	*A*	—	—	—

A, Formation of amœbæ within 24 hr

The amœbæ are at first minute (7 × 30µ) and typically *limax*-like but later reach a size of 40 × 70µ; they have been observed to multiply by binary fission Cysts (up to 25 × 30µ, smooth-walled) are found only in amœba cultures, they germinate to produce single amœbæ Possible isogametic fusions between minute flagellates can be observed in mixed cultures, but this is open to an alternative interpretation since *H clara* is phagotrophic and able to devour cells of its own size or larger and is not above resorting to cannibalism

The following hypothetical conclusions may be drawn from these preliminary observations (1) the amœbæ are diploid, (2) flagellated cells may be diploid or haploid, (3) only diploid cells can encyst, (4) haploid cells are of two mating types; (5) multiplication can occur both in the diploid and haploid states and can continue indefinitely in the latter

Multiplication of flagellated cells of diphasic amœbæ is not unknown, it has been reported, for example, for *Tetramitus rostratus*[5], together with the suggestion of a sexual phase It is not yet established that amœbæ of *H clara* can multiply for an indefinite period without reversion to flagellates, nevertheless, considerable fluidity appears to exist in the balance between haploid and diploid phases of the life-cycle, the cycle being primitive on that count as compared with other sexual Sarcodina

A cytological investigation of *H clara* is being undertaken as an aid to a proper diagnosis of the organism and to a more detailed description of the life-history

Influence of Larval Environment on Adult Size and Fecundity in the Moth *Panaxia dominula* L.

THE scarlet tiger moth, *Panaxia dominula*, is to-day found only in southern parts of the British Isles Since it was at one time a little more widespread[1] the present distribution may be due to the action of environmental limiting factors rather than to the lack of opportunity to colonize more northern parts of the country Evidence is presented here which supports this assumption

The wing-span of moths caught in several English colonies was measured from the tip of the right wing to the centre of the thorax on pinned specimens There is considerable variation in size between different colonies, insects from Devon being significantly larger than those from Berkshire (Table 1*a*) (For the difference between Axmouth and Cothill· males, $t = 10\ 37$, $P < 0\ 001$, females, $t = 10\ 89$, $P < 0\ 001$). When larvæ were collected late in development and reared to maturity under similar conditions it was not manifested (Table 1*b*) For the males, $t = 0\ 23$, $P > 0\ 80$, for females, $t = 2\ 11$, $P = 0\ 05$–$0\ 025$ It seems likely, therefore, that the differences in size between wild-caught insects are determined primarily by environmental dissimilarities between the colonies rather than by the genetic constitution of the individuals in them

The number of eggs produced by bred females was counted and their wing-span measured When productivity is plotted against wing-span it is seen that there is a significant positive correlation between them in a sample of 22 from Cothill ($r = 0\ 604$, $P < 0\ 01$), and in a sample of 6 from Kingsdown, Kent ($r = 0\ 852$, $P < 0\ 05$) The correlation is just below the 5 per cent level for 28 specimens from Axmouth ($r = 0\ 347$ With 28 points the 5 per cent value is 0 374) The data are shown in the graph (Fig 1) It may be that in Nature environmental conditions do not affect the mean number of eggs to the same extent, but the range in size in the experimental régime was considerably less than that between naturally emerging insects from the Devon and Berkshire colonies, so that the results strongly suggest that size differences in them are accompanied by a corresponding variation in egg production Similar data from other insect species are discussed by Klomp[2] In this example the smallest individuals come from colonies near the edge of the present range They probably lay fewer eggs than those from south-west England, so that reduced productivity may be one of the limiting factors

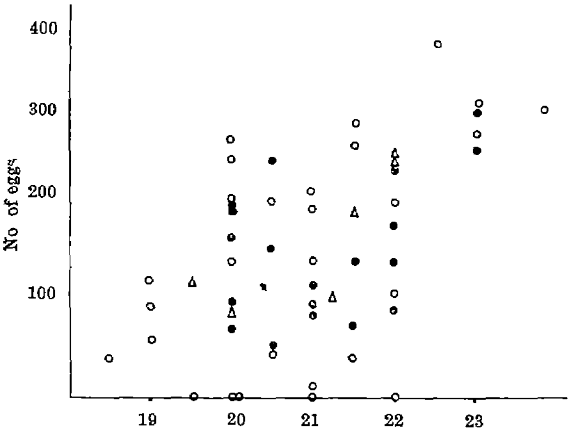

Fig 1 Regression of number of eggs on wing-span of female parent ○, Cothill, ●, Axmouth, Δ, Kingsdown In this series the size was measured from wing-tip to the join of nervures 1 and 2

Table 1 *a*, SIZE IN MM (TO NEAREST HALF MM) FROM TIP OF WIN TO CENTRE OF THORAX IN INSECTS CAUGHT WILD

Localization of Esterase in the Cuticle of the Nematode *Ascaris lumbricoides*

THE cuticle of nematodes, because of its obvious skeletal functions and its importance as a barrier to nematocides, has recently been the subject of much research Bird and Deutsch[1] and Bird[2] have greatly increased our knowledge of the structure of the cuticle of *Ascaris lumbricoides* and various other workers have added to our knowledge of the chemical composition of the cuticle[3-5] Although Fairbairn[6] states "it would seem wise to regard the integument as a fully integrated living tissue, rather than as an inert horny sheath" there has been no evidence to show that the cuticle of nematodes is metabolically active

Frozen sections (50µ) of *Ascaris lumbricoides* (from pigs), fixed in 10 per cent neutral formol saline at 4° C for 24 hr , were tested for non-specific esterase activity by two methods as described by Pearse[7] (1), the naphthol *AS* acetate - fast red *TR* salt and (2), the 5-bromo-indoxyl acetate methods

A positive result was obtained, with both methods, in the homogeneous, or matrix, layer of the cuticle but not in any of the other layers The colour was most intense at the anterior and posterior ends of the nematode In transverse sections there is a narrow gap in the deposit of stain in the homogeneous layer at the lateral lines

There was complete inhibition of colour formation after incubation with 10^{-2} *M* silver nitrate, 90–100 per cent inhibition after 10^{-4} *M* *E*600 (diethyl *p*-nitrophenyl phosphate); 50 per cent inhibition after 10^{-3} *M* cupric sulphate and 90–100 per cent inhibition after boiling for 15 min , but 10^{-4} *M* eserine appeared to have no inhibitory effect

Lipids are known to be present in the cuticle of *Ascaris* and certain other nematodes[6,8,9]. Contrary to the findings of Bird[10], a weakly positive result for lipid was obtained with oil red *O* in the homogeneous layer of the cuticle Thus the distribution of non-specific esterase coincides with the distribution of lipid in the homogeneous layer of the cuticle of

Ascaris These findings provide strong evidence in favour of the view expressed by Fairbairn[6] and by Bird[10] that the cuticle of *Ascaris lumbricoides* is a metabolically active structure The presence of at least one enzyme in the cuticle would indicate that more are present and it is possible that these enzymes are concerned with the laying down of more cuticle as the nematode increases in size after the final moult.

Esterase, inhibited by 10^{-4} *M E*600, has also been localized in the œsophageal glands, in the intestine, in the rectal glands, in the cœlomocytes, in the nervous system including the innervation processes of the body wall muscles, in the gonads, and as 'caps' of enzyme on fat globules in the hypodermis, in the dorsal, ventral and lateral lines, and in the muscles The cells of the intestine have been found to be merocrine in that they discharge esterase through the striated border without undergoing any marked changes The presence of esterase in the innervation processes of the body wall muscles, but not in the non-contractile part of the muscle other than on fat globules, would suggest that this esterase is a cholinesterase or an esterase serving a similar function in nerve transmission

ENTOMOLOGY

Effect of Chlorinated Hydrocarbon Insecticides on Insect Choline Acetylase, Condensing Enzyme and Acetylkinase

THE role of acetylcholine in the transmission of nerve impulses is by no means as well established in insects[1,2] as it is in mammals, but the presence in insect nervous tissue of large quantities of acetylcholine[3] and of enzymes capable of its rapid synthesis[4] and hydrolysis[5] is clearly established

It has also been shown that chlorinated hydrocarbon insecticides have an effect on nerve conduction in insects[6,7] and on their acetylcholine-levels[8]

That these insecticides kill insects as a direct or indirect consequence of their effect on nerve conduction has not been clearly demonstrated but it still remains the most likely explanation of their mode of action

The work reported here was carried out in an attempt to determine what effect these insecticides have on the synthesis of acetylcholine by insects, being part of a re-investigation of the effects of chlorinated hydrocarbon insecticides on the synthesis, hydrolysis and action of acetylcholine in insects

Dieldrin-susceptible house-flies *Musca domestica* L were reared at 25° C on a larval diet of 120 gm. powdered whole milk, 120 gm powdered dried yeast and 24 gm agar powder made up to 1,200 ml with water The adults were fed on glucose and on a 5 per cent aqueous glucose solution Tissue homogenates were prepared using a small Waring blender 300 adult *M domestica*, 5–10 days old, were homogenized at 0° C in 10 ml 0 25 *M* sucrose for 5 min Alternatively, the flies were decapitated, after anæsthesia by cooling, and the heads only were homogenized (300 heads/10 ml 0 25 *M* sucrose solution) as above In both cases the resultant homogenates were filtered at the pump through muslin to remove the larger pieces of cuticle, and made up to 10 ml

To determine the normal rate of synthesis of acetylcholine using either sodium acetate or sodium citrate as acetyl donor, reaction mixtures were prepared as follows and incubated in a water-bath at 30° C 2 0 ml homogenate, 0 2 ml coenzyme *A* (1 mgm /ml Light and Co , Ltd), 0 2 ml 6 6 × 10^{-2} *M* adenosine triphosphate, 0 2 ml 0 1 *M* L-cysteine, 0 4 ml 16 × 10^{-3} *M* eserine sulphate, or preferably, 0 4 ml 0 01 *M* tetraethylpyrophosphate (TEPP) (both cholinesterase inhibitors), 0 4 ml 0 4 *M* choline chloride, 0 4 ml 0 1 *M* phosphate buffer *p*H 7 0, 0 2 ml sodium fluoride (10 mgm /ml phosphatase inhibitor)

To test the effect of insecticide, sufficient was dissolved in 0 2 ml acetone to give a final concentration in the reaction mixture of 10^{-3} *M* Control experiments were carried out using 0 2 ml acetone added to the reaction mixture 0 4-ml aliquots were removed at intervals and their acetylcholine content measured using Hestrin's method[9]

The activity of the fly preparations, with and without acetone[10] and irrespective of whether acetate or citrate was the actual donor, was 0 7 μgm acetylcholine synthesized/head/hr and 1 3 μgm acetylcholine whole fly/hr The activity when expressed per gram of fresh tissue was 567 μgm acetylcholine/gm / hr for fly heads and 120 μgm acetylcholine/gm /hr for whole flies On the addition of the chlorinated hydrocarbon insecticides *pp'*DDT (dichlor diphenyl trichlorethane), dieldrin, heptachlor and lindane in 0 2 ml acetone and at a final concentration of 10^{-3} *M* the activity of the preparations remained unaltered

Smallman[4], in his demonstration of acetylcholine synthesis in the blowfly *L sericata*, found that the rate of acetylcholine synthesis from acetate by acetylkinase was considerably greater than that from citrate by the condensing enzyme working in reverse He also demonstrated that choline acetylase is much more active than either condensing enzyme or acetylkinase and that these latter enzymes appeared to control the rate of synthesis of acetylcholine

Our results on *M domestica*, in which preparations of similar activity were used, show that as in *L sericata* both pathways for the synthesis of acetyl-coenzyme *A* are present, but that in *M domestica* the rate of synthesis from acetate or citrate was the same This indicates that either choline acetylase is less active than the other two enzymes and thus acts in a rate-controlling capacity, or that in the house-fly as in the guinea pig both pathways are equally available

Lewis *et al* [8] have shown that in cockroaches poisoned and prostrated by *pp'*DDT and in cockroaches physically stimulated to prostration there is a rise in their acetylcholine-levels He postulates that this is due to the release of acetylcholine from a bound form at abnormal sites in the nervous system since his results also showed that cholinesterase was not inhibited by the above treatments Our finding that the rate of synthesis of acetylcholine in *M. domestica* is not affected by the chlorinated hydrocarbon insecticides *pp'*DDT, dieldrin, heptachlor and lindane supports Lewis's suggestion since it excludes the possibility that the increased acetylcholine-levels could be due to an increased rate of production of acetylcholine due to chemical or physical stimulation

We wish to thank the Colonial Office Pesticides Committee for financial support and Dr C T Lewis for helpful discussion and advice

Substances controlling the Rate of Beating of the Heart of *Periplaneta*

A PAPER now in the press[1] shows that the heart accelerating factor from the corpus cardiacum of the cockroach *Periplaneta americana* described by Cameron[2,3] acts by stimulating the pericardial cells to produce a second substance It is this pericardial cell factor which is responsible for the direct stimulation of the heart This communication describes the properties of the two substances

The factor from the corpus cardiacum appears to be a peptide or protein Heating extracts (prepared by grinding corpora cardiaca in insect Ringer or in distilled water) on a boiling water-bath for 5 min results in a slight increase in activity as measured on the isolated cockroach heart More prolonged heating has no further effect on the activity The activity of extracts is unaffected by evaporation to dryness at room temperature and resuspension in distilled water The dried residue can be extracted with *n*-butanol, acetone or diethyl ether without loss of activity The active factor appears to be soluble in 80 per cent ethanol, but treatment of the dried residue with absolute ethanol destroys the activity Incubation of extracts with trypsin at pH 8 or pepsin at pH 3 results in complete inactivation within 60 min at 37° C

However, Cameron[2,3] has suggested that the active substance from the corpus cardiacum is an *o*-diphenol Since Cameron's extraction technique involves the use of absolute ethanol as a solvent for the active principle, his material must be different from the material under study here Further confirmation of the non-identity of the two materials is obtained from a consideration of the behaviour on paper chromatograms of distilled water extracts of corpora cardiaca and extracts prepared according to the method of Cameron Using *n*-butanol/acetic acid/water (4 1 5) as a solvent, the activity from corpora cardiaca extracted in distilled water is associated with a ninhydrin-positive spot at R_F 0 23 Similar chromatograms using Cameron's technique have yielded highly variable results, it is sufficient to say here that no activity was ever recovered from the area around R_F 0 23 Further, a number of spots, some sensitive to ninhydrin, others to ferric ferricyanide, appeared at higher R_F values None of these spots could be detected on chromatograms developed from distilled water extracts Using phenol as a solvent, it has not been possible to detect a spot on chromatograms developed from distilled water extracts which turns pink after treatment with 0 44 *M* potassium ferricyanide On the other hand, such spots appear on chromatograms in which Cameron s technique was used to extract the corpora cardiaca It is worth noting that Cameron preferred to extract the *o*-diphenol from whole larvæ of *Tenebrio*, as the extraction from the corpora cardiaca of *Periplaneta* was difficult and unreliable[2]

The material from the pericardial cells appears to be an indolalkylamine The isolated cockroach heart is very sensitive to serotonin, the threshold for stimulation is below 10^{-7} *M* Extracts of pericardial cells activated by the factor from the corpus cardiacum have a slight and transient melanophorotropic effect on the melanocytes of the skin of the frog *Rana temporaria*, a property shared by the indolalkylamines[4] The action of extracts of the corpus cardiacum on the isolated heart of *Periplaneta* can be potentiated by first exposing the heart to a concentration of 100 μgm /ml of iproniazid, an inhibitor of the enzyme monoamine oxidase Further, 2-bromolysergic acid diethylamide, an antagonist of indolalkylamines, markedly reduced the effect of extracts of corpus cardiacum when applied at a concentration of 10^{-5} *M* These results are taken as evidence that an indolalkylamine is involved in the action of the corpus cardiacum on the heart

If activated pericardial cells are extracted by a technique designed to separate amines[5], a pharmacologically potent extract results which possesses a single ultra-violet absorption peak at 266 mμ Similar extracts of inactive pericardial cells, on the other hand, are pharmacologically inert, and possess an absorption peak at 275 mμ, with a shoulder at 286 mμ This probably represents an inactive precursor of the active factor

Extracts of active pericardial cells have been run on paper chromatograms using *n*-butanol/acetic acid/water (4 1 5) as a solvent The pharmacological activity on such chromatograms is located in the vicinity of R_F 0 5 After treatment with ninhydrin-acetic[6], a spot exhibiting blue-green fluorescence in ultra-violet light appears at R_F 0 5 This spot is absent from chromatograms of extracts of inactive pericardial cells The test is diagnostic for derivatives of tryptamine It is worth noting that the active factor from the opaque accessory glands of male insects[7] can be extracted by the same technique and shows a strong absorption peak at 266 mμ

Finally, active and inactive pericardial cells have been examined histologically Active cells are considerably larger and contain more secretion droplets A greater proportion of the active cells exhibit argentaffin granules, a characteristic feature of cells which produce indolalkylamines

I am indebted to Prof V B Wigglesworth for his continued interest and for the provision of facilities

CYTOLOGY

Chromosomes of the Orang-Utan (*Pongo pygmaeus*)

Apart from the data on the chromosome number of chimpanzees[1,2] there are no other data available concerning the number and the morphology of the chromosomes of other anthropoids While engaged on a programme of research on the phylogenetic relationships of primates, I had the opportunity of studying the chromosomes of two orang-utans (male and female, *R* 33 and *R* 34) in the Zoological Gardens of Rome

Since it is planned to publish at a later date morphometric comparative data for most species of primates, in this communication only a description of the chromosomes is given

The usual techniques for the study of chromosomes in tissue cultures were followed[3] The chromosome counts are summarized in Table 1

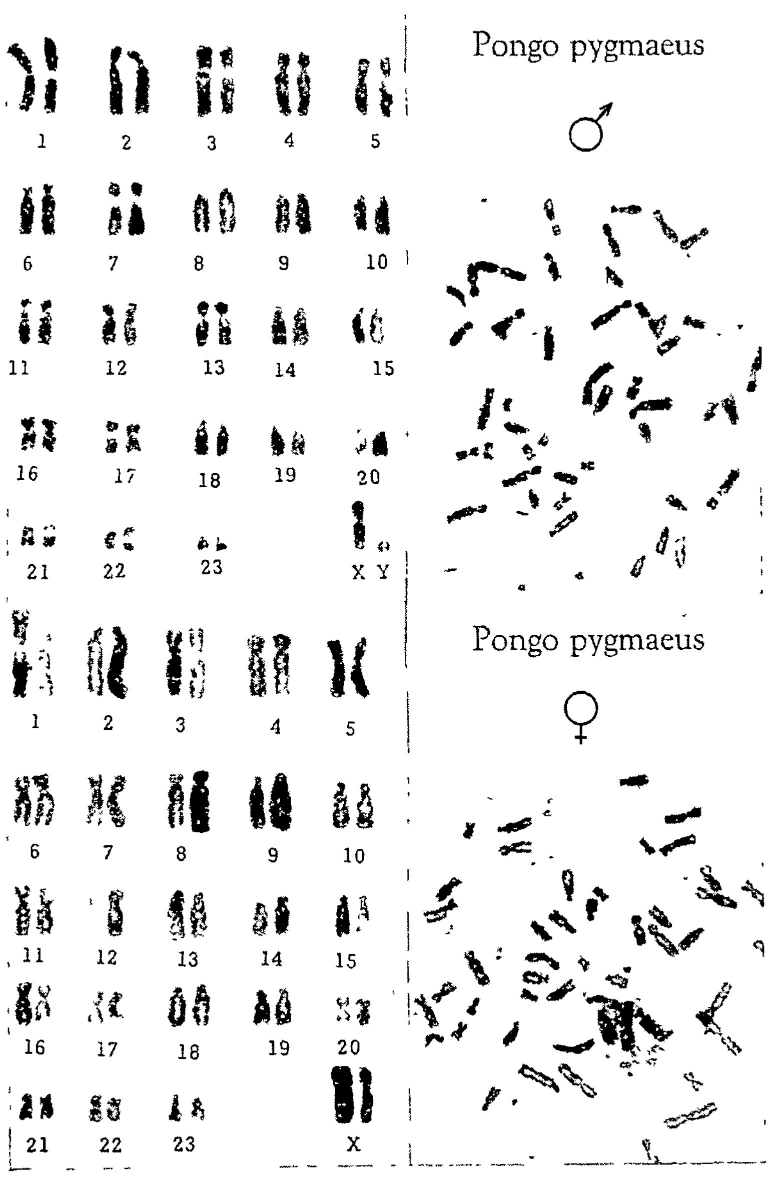

Fig 1

Table 1

2*n* =	46	47	48	49
R 33	1	2	16	1
R 34	—	3	21	—

The diploid number of the chromosomes of *Pongo pygmaeus* can thus be considered $2n = 48$, the same as that of the chimpanzee

Fig 1 shows the reconstruction, in pairs of male and female chromosomes They are arranged in a preliminary order, a more satisfactory grouping will become possible when more data become available

In Table 2 the autosomes are classified according to the position of the centromeres

Table 2

Metacentric	Submetacentric	Telocentric
1, 17, 20, 21, 22	3, 4, 5, 7, 11, 12, 13, 16, 23	2, 6, 8, 9, 10, 14, 15, 18, 19

The *X*-chromosome is metacentric, the *Y*-chromosome has a large achromatic zone

The orang-utan's karyotype shows certain similarities to the human one Chromosomes 1, 4, 5, 6 and 7 closely resemble chromosomes 1, 4, 5, 6 and 7 of man, according to the nomenclature of the Denver human chromosomes study group The three pairs of telocentric chromosomes of man (13, 14, 15) correspond morphologically and dimensionally with 10, 14 and 15 of the orang-utan The pair 23, moreover, looks like chromosome 22 of man, having one of the two arms heterochromatic As regards the sex chromosomes, the *X*-chromosome of the orang-utan shows a strong resemblance to the human one, while the *Y*-chromosome differs by having a large achromatic portion

A more careful study by means of metric analysis[3] will be required, however, before establishing such similarities

My thanks are due to the director of the Rome Zoological Gardens, Prof E Bronzini, for enabling me to study these animals

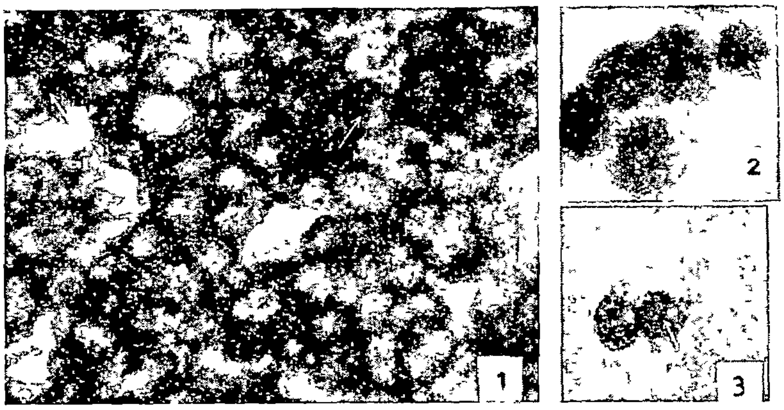
Nucleolar Succinic Dehydrogenase in Mouse Mammary Carcinoma Cells

The oxidative enzyme succinic dehydrogenase is principally localized[1] in the mitochondria and absent in the nuclei of all mammalian cells However, the enzyme had been localized in the nuclei of bird



Figs. 1 and 2. Arrows indicate the nucleoli of malignant cells in histological section and whole-cell suspension from mouse mammary carcinoma, respectively (pyronin methyl green). Fig. 3. Arrow indicates the nucleolar formazan deposition in the same type of malignant cells in suspension. (All × c. 400)

erythrocytes which according to Brachet[2] may be due to absence of mitochondria in these cells.

Nucleolar succinic dehydrogenase has been shown to be present, in normal rat liver cells[3] and also in the malignant cells[4] from epidermoid carcinoma of human cervix. Now nucleolar localization of this enzyme has been confirmed in malignant cells of a different biological material (mouse mammary carcinoma).

A suspension of intact whole cells in 0·1 *M* ice-cold phosphate buffer of *p*H 7·6 was prepared from spontaneous solid mammary carcinoma arising in *DBA* mice, which removed the endogenous substrates for succinic dehydrogenase. A portion of this suspension was smeared on glass slides for staining with pyronin methyl green and cellular sediment from the remaining portion was stained for succinic dehydrogenase[5]. A small piece of tissue from the tumour was fixed in carnoy, sectioned at 5μ thickness and stained by pyronin methyl green.

Photomicrographs show a close similarity as regards nucleolar shape, size and position of the pyronin methyl green preparations and formazan-stained nucleolar bodies (Figs. 1, 2 and 3). More than a thousand malignant cells were investigated on each slide.

Thanks are due to Dr. S. K. Brahma for active co-operation and to N. Saha for the photomicrography.

Chromosomal Lesion associated with Carcinogen-induced Tumours in Mice

PRIMARY tumours induced by polycyclic hydrocarbons have been examined by several investigators to evaluate the importance of karyotype modification in carcinogenesis[1-3]. A significant number of such tumours has been characterized by cells with aneuploid chromosome numbers. In a study of 14 fibrosarcomas induced by methylcholanthrene in a variety of F_1 hybrids of inbred mouse strains, Hellstrom[2] reported that only 4 tumours contained predominantly diploid cells. The cells comprising the remaining ten tumours were either hyperdiploid, triploid, or hypertetraploid. Marked variability in chromosomal pattern was observed from one tumour to another as well as within any one tumour.

Studies in our laboratory are under way to determine whether the cytogenetic variability observed in carcinogen-induced tumours might be correlated with the inducing hydrocarbon, sex and strain differences in tumour incidence, or the latent period, antigenicity, or growth behaviour of individual tumours. The results of these investigations will be reported in detail elsewhere.

Tumours were induced, in mice of a variety of strains, by subcutaneous injection of either 0·1 mgm. 20-methylcholanthrene or 3,4-9,10-dibenzpyrene dissolved in sesame oil (Table 1). Primary tumours or tumours maintained in isologous passage by trocar pieces for various periods were examined. Cells were prepared for chromosome studies either after brief *in vitro* culture or by direct examination of solid tumours. For tissue culture, tumour fragments were trypsinized and the recovered cells incubated in Eagle's minimum essential medium containing 10 per cent fœtal bovine serum. Variability in time of attachment and initiation of cell division, usually 24–48 hr., determined the interval in culture prior to examination. Squash preparations of metaphase cells were obtained by standard colchicine and hypotonic citrate pretreatment, aceto-orcein fixation and staining. For direct examination of solid tumours, mice were injected, 1 hr. prior to death, with colchicine. Tumour fragments were minced in hypotonic citrate solution and fixed and stained with aceto-orcein. Short-term growth in tissue culture offered distinct advantages over the use of material derived directly from the mouse since larger numbers of dividing cells, as well as chromosomal preparations of superior morphological detail, were obtained. The cytogenetic variability manifested by these carcinogen-induced tumours is illustrated in Table 1. No distinction between tumours induced by methylcholanthrene or dibenzpyrene is apparent. Similar to Hellstrom's findings, those tumours represented by a true diploid modal chromosome number were seen to be composed of some aneuploid cells.

The presence of chromatid breaks, occurring regularly in a certain proportion of the cells of 20-methylcholanthrene- and 3,4-9,10-dibenzpyrene-induced tumours, has been observed in preparations directly from solid tumours as well as from cultured material (Fig. 1). Table 2 indicates the frequency of cells with such breakage for several tumours of each carcinogen group. Only those cells selected as suitable for accurate chromosome counts were scored for breakage. Characteristic breaks were noted in cultured material which was not subjected to colchicine. Similar lesions have not been seen in other murine cells,

Table 1 DISTRIBUTION OF CHROMOSOME NUMBERS OF METAPHASE CELLS IN CARCINOGEN-INDUCED TUMOURS

	D-X	19	8	37

from normal or tumour tissues, cultured in our laboratory

Although the chromosomal discontinuity appears to be 'complete' most frequently, a thin interconnecting thread is occasionally seen Rarely the break in the chromatid arm is only partial In more than half the total number of metaphase cells with this chromatid lesion, only one break per cell was found Higher numbers of breaks, up to 5 per cell, occurred with decreasing frequency The number of breaks in each cell is apparently not related to ploidy Breaks were present with a relatively high frequency in tumour *M*-I, which was originally examined in its 6th transplant generation This tumour was again studied in its 11th passage generation and the breakage frequency was found to be similar

At this time, we feel that no preferential breakage sites characterize these tumours We have noted that for any one tumour there is occasional evidence of breaks occurring at comparable sites on the chromosomes of different cells Investigations are under way to clarify this point, elucidation, however, will be made difficult by the lack of individuality of the mouse chromosome, in addition to the well-known occurrence of cryptic structural changes

Whether or not the portion of the chromatid arm distal to the break remains attached through the next cell-division cycle is not known Such a process could occur by means of a non-visualized chromosome matrix, or by a process of re-healing That the chromatid fragment is at least sometimes lost was apparent A portion of a metaphase chromatid was occasionally missing or a chromatid fragment was sometimes found distant from a deleted chromosome At times the fragment was seen 'paired' to the sister chromatid on the side opposite the proximal portion

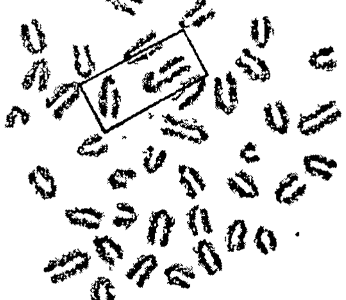

Fig 1 Metaphase cell from tumour *M*-I, containing 43 chromosomes Two chromatid breaks are demonstrated in area outlined (× 1,760)

of the broken chromatid. The possible contribution of the observed chromatid breakage to structural changes within the chromosomal complement will require further analysis.

The work reported in this communication was supported in part by a grant from the American Cancer Society and in part by Contract *SA*-43-*ph*-2445 from the Cancer Chemotherapy National Service Center, National Cancer Institute, Public Health Service, Bethesda, Md.

GENETICS

Effect of Kinetin on the Fertility of some Strains of *Neurospora crassa*

In experiments with *Neurospora crassa*, some strains when crossed are highly infertile and, therefore further genetic analysis is difficult. This communication reports the effects of an addition of kinetin (6-furfurylamino-purine)[1] on the fertility of some strains of *Neurospora crassa* which are normally highly infertile.

The strains used were all derived from the Abbot and/or Lindegren wild-types[2] and had become infertile as a result of either ultra-violet irradiation (designated *A* in Table 1) or of selection for ascospore size (Lee, B. T. O., unpublished results) (designated *B* in Table 1).

Crosses were set up between various strains of the *A* and *B* series on a medium favouring sexual reproduction with kinetin (0–10 p.p.m.) added. The fertility was assessed after incubation for 15 days at 25° C. Each treatment was replicated five times. The fertility was measured by counting the number of perithecia per slope and ascospore production assessed on an arbitrary scale 0–10, in which 0 is equivalent to a complete lack of ascospore production and 10 corresponds to normal wild-type production of ascospores. The results are given in Table 1. It is evident that the perithecial production in eight of the nine crosses used is greatly increased by the presence of kinetin. Estimates of ascospore production follow a similar trend. It is notable that kinetin had no effect on the cross *B* 21 × *B* 14.

Table 1. Perithecial and Ascospore Production with Added Kinetin

Cross		Kinetin (p.p.m.)					
		0.0	0.5	1.0	2.0	4.0	10.0
A 13 × *A* 18	P*	64	122	128	154	146	152
	A†	2	2	3	3	4	3
A 12 × *A* 13	P	60	104	116	102	122	106
	A	2	4	4	4	4	3
A 19 × *A* 14	P	12	96	154	252	206	212
	A	1	3	4	6	5	5
A 21 × *A* 16	P	26	80	72	104	92	88
	A	1	4	4	5	4	4
B 17 × *B* 19	P	4	82	104	84	158	196
	A	0	2	2	2	4	4
B 21 × *B* 14	P	8	16	24	14	22	18
	A	1	1	1	1	1	1
B 1 × *B* 3	P	20	34	106	66	74	86
	A	1	2	3	1	2	3
B 1 × *B* 7	P	5	76	94	106	118	126
	A	0	2	3	3	4	3
B 16 × *B* 8	P	8	76	108	92	106	122
	A	0	2	3	2	4	4

* P = No. of perithecia produced per slope (mean of 5 replicates).
† A = Estimated ascospore production per slope (mean of 5 replicates).

It is thought that this effect of kinetin on the crossing behaviour of *Neurospora crassa* might assist in the study of many strains the infertility of which on crossing has hitherto prevented a genetic analysis.

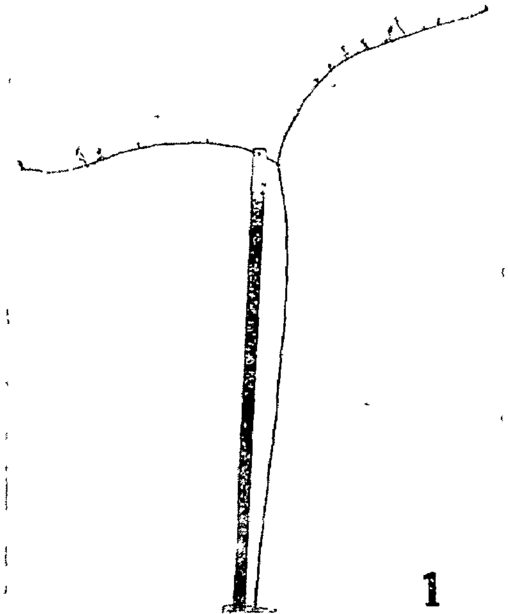
Haploidy in Jute (*Corchorus olitorius* L.)

Haploidy was first reported to occur in *Datura stramonium* by Blakeslee *et al.*[1] Since then, haploids occurring spontaneously or induced under artificial conditions have been recorded in many flowering plants[2]. As far as we are aware, haploidy in *Corchorus* has not yet been reported. Datta[3] reported a case of



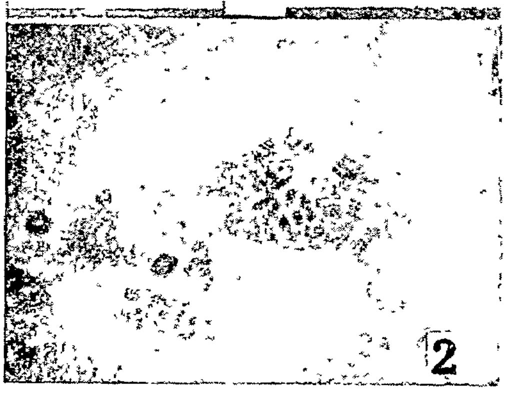


Fig. 1. The haploid *Corchorus olitorius* (*JRO*-632) plant (× 1/14)
Fig. 2. Seven somatic chromosomes in the root-tip cell (× 1,700)

polyembryony in *Corchorus* without, however, any cytological analysis of the twin seedlings

From a selection of X-ray-irradiated progenies of 70,000 r treatment of the X_3 generation of *Corchorus olitorius* (*JRO*-632) in 1960, seven variants were found from a culture of healthy, vigorously growing normal plants These plants with comparatively slender stem and small leaves were very late-flowering and the pod was small and stumpy Among these variants, one plant was characterized by the presence of a very short and slender stem (Fig 1) (length 97 5 cm , thickness 5 2 mm) and bearing a few flowers, from which only nine mature pods developed, measuring 1–1 5 cm in length and 4–5 mm in breadth Six of the pods were empty In the remaining three pods, one to three full seeds and two to three shrivelled seeds were obtained

In most of the anthers, unseparated tetrads with collapsed walls were found The anthers of the flowers did not dehisce, pollen sacs were empty with collapsed walls, though two full grains, taking stain in iodine, were found in a flower

Of the seven full seeds, which are similar morphologically to the seeds of normal plants, three were germinated, from these, chromosome investigations were carried out In the orcein squash of root-tip meristem of all the three seeds, seven chromosomes were counted from the metaphase plates (Fig 2)

The seeds having haploid number of chromosomes may have arisen by parthenogenesis of a cell from the female gamete[4]

VIROLOGY

Transmission of Lapinized Rinderpest Virus by Contact between Rabbits

Rabbits are readily infected with lapinized rinderpest virus administered parenterally, but contact infections are alleged not to occur[1,2] Protocols, however, have not been published yet

Eight groups of twenty rabbits were randomly paired and each pair was closely confined in a cage measuring 45 × 45 × 45 cm One rabbit of each pair was given 1,000 ID_{50} of lapinized rinderpest virus intravenously Rectal temperatures were recorded daily In the first trial insufficient attention was paid to the risk of transmission by clinical thermometers for we have found since that lapinized rinderpest virus can be recovered from the fæces of infected rabbits and that intrarectal instillation of the virus readily infects In subsequent trials different thermometers were used to record the temperatures of inoculated and uninoculated rabbits

Close contact was maintained until the inoculated rabbit died Thereafter the uninoculated rabbits were observed for a further period of 10 days, after which they were killed and examined for signs of rinderpest In the final trial the period of observation was extended to 30 days Uninoculated rabbits which developed a fever were killed and examined. Tissues from those having suggestive lesions were collected, emulsified and inoculated into other rabbits

All eighty inoculated rabbits were infected and all died In the first trial one of the in-contact rabbits contracted rinderpest and we now believe that transmission occurred rectally via the thermometer In the subsequent trials two in-contact rabbits had suggestive lesions but virus was not recovered from their tissues and infection was not considered to have occurred

Our findings have confirmed the earlier statements that contact transmission of lapinized rinderpest virus does not occur between sick and healthy rabbits Direct contact, nevertheless, is the primary mode of transmission of wild strains of rinderpest and all authenticated outbreaks in previously disease-free countries have been linked to the importation of live animals from endemic areas[5] Lapinized rinderpest virus has undergone many serial passages in rabbits and in the process has become attenuated for cattle and, at the same time, highly virulent for rabbits It has also lost its ability to transmit by contact In this respect it simulates the Kabete *O* strain of rinderpest virus which has been 'needle-passaged' in cattle for many years and which does not spread readily between sick and healthy cattle although it is highly virulent for cattle[3] Presumably the route of infection with both strains has favoured the selection of mutants deficient in natural invasiveness Both strains still, however, induce gross changes in the alimentary tract[4]

Recognition of the possibility of selecting mutants of virulent strains of virus which do not spread by contact should stimulate the search for a selection of similar mutants of attenuated strains intended as live virus vaccines

We wish to thank Mr H R Binns, director of the East African Veterinary Research Organization, for his advice and encouragement and permission to publish this communication

Photo-Reactivation of Tobacco Mosaic Virus *in vivo*

Tobacco mosaic virus, inactivated *in vitro* by ultra-violet irradiation, could not be photo-reactivated by exposing plants, inoculated with the inactivated virus, to light[1,2] However, ribonucleic acid preparations from tobacco mosaic virus could be photo-reactivated in this manner, following inactivation by ultra-violet light[1,3] Siegel *et al* [4] investigated the effects of ultra-violet light on tobacco mosaic virus and tobacco mosaic virus nucleic acid, at different times after inoculation of *Nicotiana glutinosa* plants, on which local necrotic lesions are formed They interpreted their results to suggest that the nucleic acid of tobacco mosaic virus is freed from its protein moiety during a lag period of approximately 2 5 hr following inoculation and before the infective centre begins to increase in resistance to ultra-violet light If this model is correct, and the nucleic acid of tobacco mosaic virus separates from the protein, then it should be possible to photo-reactivate the nucleic acid during the period when the separation occurs.

Bawden and Kleczkowski[5] reported experiments to test this hypothesis, but concluded that the photo-reactivation effects observed in their experiments could always be attributed to the effects of ultra-violet light on the 'capacity' of *N glutinosa* leaves, capacity being defined as the ability of a leaf to support the multiplication of tobacco mosaic virus to the extent of forming local lesions The effect of ultra-violet light on capacity can be determined by irradiating leaves prior to inoculation, and in experiments designed to study the direct inactivation of tobacco mosaic virus in leaves, the dosage of ultra-violet light must be such that the capacity remains unimpaired

Table 1 EFFECT OF ULTRA-VIOLET LIGHT ON THE CAPACITY OF LEAVES OF *N glutinosa*

Dose (min)	Experiment No 1	2	3
2	0 97	1 00	
3	1 00	0 99	
4	0 91	0 99	
5	0 75	0 79	
6			0 56
8			0 49
10			0 24

Each figure represents the fraction of local necrotic lesions developed on detached half-leaves of *N glutinosa* irradiated before inoculation with the *U*2 strain of tobacco mosaic virus as compared with un-irradiated half-leaves

Table 1 shows the effect of ultra-violet light from a Philips *TUV*30 germicidal lamp (90 per cent transmission at 2537 Å) on the capacity of detached leaves of *N glutinosa* irradiated at 30 cm from the lamp and immediately inoculated with the *U*2, or mild, strain of tobacco mosaic virus Clearly, capacity is affected by prolonged irradiation prior to inoculation, and in subsequent experiments no period of irradiation longer than 90 sec was employed The *U*2 strain of tobacco mosaic virus was used as it is 5 5 times more sensitive to ultra-violet light than the *U*1, or common strain Suitable killing fractions for infective centres of *U*1 tobacco mosaic virus could not be obtained without impairing capacity *N glutinosa* plants were inoculated by means of a paint brush with an inoculum containing 10^{-3} mgm /ml of ultracentrifugally purified *U*2 tobacco mosaic virus in *M*/15 phosphate buffer, *p*H 7, containing 4 per cent 'Celite' as abrasive In all experiments glasshouse grown plants were placed in a growth room 16–20 hr before inoculation, at a temperature of 25° ± 1° C , and continuous fluorescent light of 800 ft -candles intensity Inoculations were carried out under these conditions, while irradiation was done under the ultra-violet lamp in the same room Leaves were detached prior to irradiation, placed on cotton wool in shallow trays and irradiated For each treatment 3 leaves from each of 8 plants were used, one half of each leaf was covered to serve as the unirradiated control Leaves were retained in the light, or dark, in the growth room for 24 hr following irradiation and then transferred to continuous light of 800 ft -candles intensity and a temperature of 25° ± 5° C , for a further 2 days, until lesions were counted For each treatment the lesion totals from the irradiated halves of each leaf were compared with the totals from the unirradiated halves, and since infective centres lead to the formation of local lesions the fraction of infective centres surviving irradiation was calculated

Table 2 PHOTO-REACTIVATION OF TOBACCO MOSAIC VIRUS A DIFFERENT TIMES AFTER INOCULATION

Exposure after inoculation	Time after inoculation (hr) 2	2 5	3 5	3 75	4 0			4 25	6 0	
Light	0 24	0 25	0 42	0 47*	0 45	0 46	0 45	0 57*	0 61*	0 5
Dark	0 23	0 24	0 40	0 41*	0 39	0 40	0 32	0 47*	0 59*	0 5

Figures represent the fraction of infective centres of *U*2 tobacco mosaic virus on *N glutinosa*, surviving a dose of 90 sec ultra-violet light

* Experiments carried out at a dose equivalent to 75 sec ultra-violet light

Table 2 shows the results from photo-reactivation experiments carried out at different times after inoculation In the period from 2 to 3 5 hr after inoculation no photo-reactivation could be demonstrated It is clearly evident that from 3 75 to 5 hr after inoculation photo-reactivation, as measured by the difference in the fraction of infective centres surviving irradiation in leaves exposed to light, as compared with dark, has been demonstrated This period of photo-reactivation corresponds to the period of rapid change in sensitivity to ultra-violet irradiation shown by Siegel and Wildman[2] to commence 2 5 hr after inoculation with the *U*2 strain of tobacco mosaic virus Siegel and Wildman retained plants at a lower temperature, 20° C , and a higher light intensity, 1,000 ft -candles, than those used in the present experiments However, it is evident from the fraction of infective centres surviving when leaves are exposed to light following inoculation (Table 2) that conditions used in the experiments reported here resulted in a change in sensitivity commencing at approximately 2 5 hr after inoculation, the same time at which Siegel and Wildman reported a change

The demonstration of photo-reactivation supports the hypothesis that nucleic acid, free from the protein moiety, is present in the infective centre for a period of time following the inoculation of tobacco mosaic virus Siegel and Wildman[4] suggested that the separation of protein and nucleic acid occurs during the lag period of 2 5 hr before the infective centre begins to increase in resistance However, in a later publication, Wildman[6] considered that the process of protein removal from the nucleic acid may occupy a period of up to 5 hr after inoculation Since it has not been possible to demonstrate photo-reactivation of tobacco mosaic virus until 3 75 hr after inoculation it would appear that free nucleic acid is not present in the infective centre until this time period has elapsed Thus it seems more realistic to propose that the separation of the protein moiety and the nucleic acid of tobacco mosaic virus in an infective centre on a leaf of *N glutinosa* takes place following the lag period and when the infective centre is already undergoing an increase in resistance to ultra-violet irradiation

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, October 23

University of London (in the Physiology Theatre, University College, Gower Street, London, W C 1) at 5 p m —Prof J N Davidson "The Biosynthesis of Polynucleotides" * (Further lecture on October 30)

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Is Automation Making Satisfactory Progress ?"—opened by Prof A Tustin

University of London (at King's College, Strand, London, W C 2), at 5 30 p m —Dr F A E Pirani and Dr G F Elliott "Ballistic Missiles and Nuclear Weapons—Missile Ballistics" * (Second of seven lectures in War Studies Further lectures on October 30, November 6, 13, 20 and 27)

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Mr W Reddish "Chemical Structure and Electrical Properties of High Polymers"

Tuesday, October 24

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr R W Hockney and Dr T O Jeffries "The Use of Analogue Computers in Predicting the Space–Time Behaviour of Nuclear Reactors"

Royal Institution of Naval Architects (at the Institute of Marine Engineers, 76 Mark Lane, London, E C 3), at 5 30 p m —Dr J E Richards "High Temperature Gas-cooled Reactors"

University of London (at King's College, Strand, London, W C 2), at 5 30 p m —Père Roland de Vaux (Jerusalem, Jordan) "Tell el-Far'ah – Tirzah—Excavating a Biblical City" *

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr L Brent "Some Current Problems in Transplantation Immunity" * (Third of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

University of London (at the School of Oriental and African Studies, London, W C 1), at 5 30 p m —Dr L Dumont (Paris) "The Conception of Kingship in Ancient India, and Anthropologists' View" * (Further lecture on October 25)

Wednesday,' October 25

Polarographic Society (at the School of Pharmacy, 29/39 Brunswick Square, London W C 1), at 2 45 p m —Prof M von Stackelberg (Bonn University) "Some Special Problems in the Polarography of Indium and Tellurium"

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S W 7), at 4 p m —Annual General Meeting Dr G E R Deacon, F R S "Navigation and the Science of the Sea" (Duke of Edinburgh's Lecture)

Bone and Tooth Society (at the Institute of Orthopædics, 234 Great Portland Street, London, W 1), at 4 30 p m —Symposium on "Fluorides"

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr R J Halsey "Global Communication" (Chairman's Address)

British Institution of Radio Engineers, Computer Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Symposium on "Digital Differential Analysers".

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Sir Kenneth Hague "Coordination in Engineering Research and the Conservation of Scientific and Technical Manpower" (Presidential Address)

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S W 7), at 6 p m —Mr A M P Brookes "Structures and Components at Elevated Temperatures"

Society of Chemical Industry, Food Group—Nutrition Panel (at 14 Belgrave Square, London, S W 1), at 6 15 p m —Meeting on "Foods Low in Salt"

Society of Instrument Technology, Data Processing Section (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr W H Baker and Mr P Huggins "Mechanising Factory Shop Floor Form Filling".

British Psychological Society, Medical Section (at the Royal Society of Medicine, 1 Wimpole Street, London, W 1), at 8 30 p m —Mr Emanuel Miller "Personal and Social Approaches to Adolescents' Problems"

Thursday, October 26

Royal Society (at Burlington House, Piccadilly, London, W 1), at 10 30 a m —Symposium on "Biochemistry and Nutrition" under the leadership of Prof R A Morton, F R S , to celebrate the Centenary of the Birth of a former President of the Society, Sir Frederick Gowland Hopkins, O M , 1861–1947

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr A S G Curtis "The Capabilities of a Living Cell" *

Institution of Electrical Engineers (joint meeting with the British Section of the Société des Ingénieurs Civils de France, at Savoy Place, London, W C 2), at 5 30 p m —Mr P M J Ailleret "A Comparison between Generation and Transmission Problems in Great Britain and France"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London W C 1), at 5 30 p m —Dr Henry Harris "The Transfer of Information from Nucleus to Cytoplasm" * (Fourth of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

Friday, October 27

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W 12), at 4 p m —Prof L S Penrose, F R S "Mongolism" *

Royal Astronomical Society (in association with the Geological Society, at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p m —Geophysical Discussion on "Interpretation of Geophysical Surveys" Chairman Dr W Bullerwell Speakers will include Prof J M Bruckshaw, Dr M H P Bott, Mr G Tait and Mr A N Thomas

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Prof M A Ellison "Cosmic Rays from the Sun"

Friday, October 27—Saturday, October 28

Institute of Biology (in the Lecture Hall of the Royal Geographical Society, 1 Kensington Gore, London, S W 7), at 10 a.m daily—Symposium on "The Better Use of the World's Fauna for Food"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Research Assistant (Animal Behaviour) (graduate in psychology or zoology) in the Department of Psychology—The Registrar The University, Leicester (October 27)

Scientific Officer (with a good honours degree in chemistry or botany) in the Weeds Section, to carry out research on the adsorption, mobility and persistence of herbicides in soils—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (October 28)

Assistant Lecturer (with a science qualification and preferably a medical qualification) in Physiology—The Secretary, St Mary's Hospital Medical School (University of London), Paddington, W 2 (October 30)

Senior Lecturer or Lecturer (with medical qualifications registrable in this country) in Virology, and a Senior Lecturer or Lecturer (with medical qualifications registrable in this country) in Immunology—The Registrar, The University, Manchester 13 (October 30)

Analyst (with at least a second-class degree in chemistry or biochemistry or considerable experience in analytical chemistry) in the Department of Chemical Pathology—The Registrar, The University, Leeds 2 (October 31)

Assistant Lecturer (with special qualifications in experimental physics, aeronomy or astronomy) in Applied Mathematics—The Secretary, Queen's University, Belfast, N Ireland (October 31)

Lecturer in Biology—The Principal, Bede College, Durham (October 31)

Lecturer (with a major interest in elasticity or the theory of plasticity) in Mechanical Engineering—The Registrar, Manchester College of Science and Technology, Manchester 1 (October 31)

Research Assistant (graduate in physics or electrical engineering) in the Department of Physics, to investigate microwave radiation from plasmas—The Registrar, University College of Wales, Aberystwyth (October 31)

Senior Lecturer (with a good grounding in biochemistry and clinical medicine or clinical pathology, and preferably experience of a hospital biochemical laboratory) in Chemical Pathology—The Registrar, The University, Leeds 2 (October 31)

Chair of Geology in the University of Malaya, Kuala Lumpur —The Secretary Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Malaya and London, November 1)

Demonstrator (graduate who intends to read for a higher degree) in Pharmacognosy—The Registrar, The University, Nottingham (November 1)

Assistant Lecturer in Physics—The Registrar, Manchester College of Science and Technology, Manchester 1 (November 4)

Assistant (with a degree in science and/or agriculture (preferably honours), and interest in grassland husbandry and an aptitude for investigational and research work) to the Advisory Officer in Grassland Husbandry—The Secretary, West of Scotland Agricultural College, Blythswood Square, Glasgow, C 2 (November 7)

Senior Lecturer or Lecturer (qualified in applied mathematics) in Mathematics)—The Registrar, University College of North Staffordshire, Keele, Staffs (November 7)

Lecturer or Assistant Lecturer (with special interests in the geography of the Americas) in Geography—The Registrar, The University, Southampton (November 11)

Vokes Research Fellow (preferably with a special interest in fluids and elastic theory) in the Department of Mechanical Engineering—The Secretary and Registrar, The University, Southampton (November 11).

Experimental Officer or Senior Experimental Officer (with H N C, a degree or similar qualification, and preferably experience with transistor circuits and pulse equipment) in the Department of Physics, to develop and construct special electronic devices required for experimental work on a tandem accelerator—The Registrar, The University, Manchester 13 (November 13)

Scientific Officer or Senior Scientific Officer (honours graduate with appropriate training and research experience), to work as a member of a team undertaking research on hill sheep nutrition—The Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh 12 (November 13)

Lecturer (preferably with qualifications and/or experience in palæontology or stratigraphy) in Geology at the Royal College, Nairobi—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 18)

Reader in Fluid Mechanics at Imperial College—The Academic Registrar University of London, Senate House, London, W C 1 (November 20)

Senior Research Assistant to the Immunopathology and Fluorescence Microscopy Research Group, to work in the University Department of Pathology on immunological and histological methods—The Secretary, The University, Aberdeen (November 20)

Senior Lecturer in Physiology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, November 25)

Lecturer in Zoology at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia, November 30)

Senior Lecturers/Lecturers in the School of Physiology within the Faculty of Medicine, University of New South Wales, Australia—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (November 30)

Assistant Professor (Poultry Genetics) (with a Ph D or equivalent in poultry genetics), to develop a research programme in poultry genetics and to carry some teaching responsibility—Head, Department of Animal Science, University of Alberta, Edmonton, Alberta, Canada (January 1)

Agricultural Chemist (male, under 35, with a degree in agriculture with chemistry as a major subject, or a science degree with postgraduate experience in soil or agricultural chemistry) in the Department of Land Utilization, Swaziland, to develop an agricultural chemistry section at Malkerns Research Station, organize routine analysis of soil and plant material, and to conduct an investigation into fertility problems in soils, particularly leached types of tropical soils—The Director of Recruitment, Department of Technical Co-operation, Carlton House Terrace, London, S W 1, quoting RC 213/141/01/T

Assistant Experimental Officer (graduate, or holding H N C, or an equivalent qualification, or, if under 22, G C E "A" level, O N C, etc, or equivalent, and interested in both chemical analysis and working with animals) in the Chemistry Department, to assist in studies of mineral metabolism in cattle—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref 61/15

Assistant Professor in Pharmacology—Prof M F Murnaghan, University of Ottawa, Ottawa, Ontario, Canada

Biochemist or Chemist (with a research degree and experience in the chemical industry involving research on new products and processes and their technical or commercial development, and preferably experience in the virology and antibiotics fields), for work concerned with the development and commercial exploitation of inventions in the public interest—The Director of Administration, National Research Development Corporation, 1 Tilney Street, London, W 1

Chief Laboratory Technician—Head of the Department of Applied Physics, Northampton College of Advanced Technology, St John Street, London, E C 1

Fisheries Officer (with a university degree in science with experience in up to date fishing methods, and the storage, marketing and distribution of fish) in the Department of Agriculture and Fisheries, Bermuda, to undertake the development of all aspects of the fishing industry in Bermuda—The Director of Recruitment, Department of Technical Co-operation, Carlton House Terrace, London, S W 1, quoting RC 289/13/01/T

Head (with an honours degree in mathematics of a British university and at least three years experience of teaching) of the Mathematics Department—The Headmaster, Pocklington School, West Green, Pocklington, Yorks

Lecturer (with some knowledge of logical design) in Computing—The Secretary, Northampton College of Advanced Technology, St John Street, London, E C 1

Physicist, Basic grade (with a first- or second-class honours degree), for routine and development work in hospital physics—The Secretary, Lambeth Hospital, Brook Drive, London, S E 11

Postgraduate Student (recent graduate with a good degree in physics or physical chemistry) in the Department of Physics, to research under the supervision of Dr J G Powles on some aspect of magnetic resonance—The Registrar, Queen Mary College (University of London), Mile End Road, London, E 1

Research Assistant (honours graduate) in Physics—Clerk to the Governors, Woolwich Polytechnic, London, S E 18

Research Assistant (with a good honours degree in physics) in Physics, for work in the field of vacuum physics—Head of the Department of Physics, The Polytechnic, Regent Street, London, W 1

Research Assistant (with graduate or equivalent qualifications and appropriate experience in electronic instrument design and construction), to take part in a space research project under Dr T R Kaiser The work will involve the development of instruments for installation in rockets and satellites—The Registrar, The University, Sheffield

Research Fellow in Physical Chemistry, for work with Prof M C R Symons on the study of unstable intermediates including spectrophotometric and electron spin resonance techniques—The Registrar The University, Leicester

Research Scholar, and a Research Fellow in the Department of Chemistry, for work on aluminium–nitrogen and aluminium–phosphorus polymers—The Registrar, The University, Leicester

Senior Physicist (graduate in physics, preferably with honours, and normally with five years experience of hospital physics or with radio-elements) in the Radiotherapy Department—The Secretary, Lambeth Hospital, Brook Drive, London, S E 11

Senior Research Fellowship at the University of Melbourne, available in any one of the academic subjects taught there—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1, or Dean of Graduate Studies, University of Melbourne, Parkville, N 2, Victoria, Australia

SCIENTIFIC MAN-POWER IN BRITAIN

DURING the latter part of 1960, the Statistics Committee of the Advisory Council on Scientific Policy made a fresh survey of the long-term demand for scientific man-power in Britain, supplementing that previously made by the Council's Committee on Scientific Manpower in preparation for its survey of scientific and engineering man-power in 1956 This survey is intended to relate the subsequent expansion of educational institutions to the Council's plans for training scientific and technological man-power during the next decade and to the demands for employment which might be expected to arise by about 1970 This survey has now been published as an appendix to a memorandum by the Committee on Scientific Manpower* Although the Statistics Committee did not regard the nature of the evidence at its disposal, particularly in relation to future demands for employment, as sufficiently precise for detailed conclusions to be drawn, the report should none the less form a useful guide to the Council in determining its general policy in training scientific man-power

The Committee on Scientific Manpower points out that much might happen to invalidate the estimates made by the Statistics Committee, and the assumptions made will not necessarily be fulfilled It is believed, however, that the present shortage of scientific man-power will continue for a long time in the educational profession, and in those disciplines which involve a high degree of mathematical skill While the Statistics Committee has calculated the balance of supply and demand from its own assessment of the soundest of the alternatives before it, the report provides the material for a range of differing assumptions to be applied should further evidence become available

In its terms of reference, the Statistics Committee was asked to assume that the university population would be raised to 170,000 by 1971, and that the projected increases in the output of qualified man-power for colleges of advanced technology and similar institutions would also be achieved Its estimates of supply accordingly assume that suitable school-leavers will wish to enter such institutions in sufficient numbers to fill all scientific and technological places, that the present pattern of university output will continue (including lengths of courses and proportions of overseas students), that technological education will develop on lines at present foreseen (including present standards of professional qualification), and that the present pattern of migration, and loss by death, retirement, marriage, etc , will continue The Committee on Scientific Manpower believes that in so far as these assumptions are closely linked with the physical limits of expansion, the report gives a substantially accurate picture of the numbers likely to qualify during the next decade, though changes in the pattern of output from the universities and in the lengths of courses are to be expected It is assumed that the Committee's estimate in its earlier report of a total 'qualified' population of 72,200 scientists and 100,800 engineers in 1959 was reasonably comprehensive

On these assumptions the qualified man-power available is expected to rise to 77,400 scientists and 100,800 technologists at the beginning of the 1960–64 period, 107,700 scientists and 147,300 technologists at the beginning of 1965–69, 149,300 scientists and 196,600 technologists at the beginning of 1970–74, and 206,000 scientists and 257,500 technologists in 1975. The numbers qualifying in each year are estimated as rising from 6,490 in science and 9,055 in technology in 1959–60, of whom 8,345 will be from universities and 7,200 from technical colleges, etc , to 8,660 in science and 11,620 in technology in 1964–65, 11,810 in science and 14,770 in technology in 1969–70, and 14,200 in science and 16,470 in technology in 1975–76, when 17,370 will come from the universities and 13,300 from technical colleges, etc These figures are believed to provide a sound basis from which to consider possible demand, and stress is laid on the relatively low figure for wastage, due in part to the comparatively low average age of scientists and technologists in employment

The assessment of demand has been accepted as essentially more hazardous than the calculation of supply, and in this review a more detailed assessment of each sector of employment has been used than in 1956 and of the main industrial groups separately Moreover, the Statistics Committee has avoided restrictive assumptions and endeavoured to avoid significantly under-estimating the demand for employment or drawing too fine a balance between supply and demand An exclusively vocational approach has also been avoided, and account taken of the tendency, which may well accelerate, for scientists and technologists progressively to invade fields of employment outside their disciplines, such as management, public services and elsewhere

The estimates of demand depend on assumptions as to the programmes of research in the Civil Departments (particularly the research councils) and the expenditure on defence, the use of qualified man-power in each group in private industry, the ratio of scientists to technologists, and the proportion of the working population in 1970 in each industry, the requirements for teaching staff implicit in filling all planned and projected places in further education and in schools, and the form of the curve of demand between 1959 and 1970 As regards industrial employment, the most important assumption, made on the basis of inquiries, is that the speed of absorption of qualified man-power in technologically advanced industries tends to decline when a density is reached at which the technologies concerned are fully manned Thereafter, the rate of absorption tends to be governed by the size of the industry and by replacement, until far-reaching but unknown technological changes create an entirely new industrial situation, but in a large industry there is reason for believing that technological 'break-throughs' as such do not normally involve taking on significant additional resources of man-power The most advanced firms in certain leading industries in both the United Kingdom and the United States already appear to be exhibiting these tendencies, and the Committee assumes therefore that, for one economic reason or another, the density of employment of scientific man-power within these industries will rise to the level already characterizing the best firms in that group

---

* *The Long-Term Demand for Scientific Manpower* Pp ix+26 (Cmnd 1490) (London H M Stationery Office, 1961) 1s 9d net

On these assumptions, and subject to the reservations indicated, the Statistics Committee concludes that the overall supply and demand for qualified man-power will not be much out of balance at the end of 1965 If anything, a slight shortage of technologists will be balanced by a slight surplus of scientists, and any possible divergence of supply and demand falls in the second five years of the 1960–70 decade The survey suggests that the number of qualified persons per thousand in the working population can be expected to rise from 7 to 13 during the next ten years, and in many engineering industries as well as in the chemical industry, this doubling in a decade will be exceeded over the whole of the industry

In presenting the report, the Committee on Scientific Manpower describes this doubling, with some justification, as in itself a potential technological revolution, and the report endorses the assumption that by 1970 there will be substantial improvements in pupil–teacher ratios and in the proportion of graduate teachers in the schools in Britain, notwithstanding big increases in the numbers of pupils in the higher forms and a doubling of the number of postgraduate students in the universities Overall, the Committee's assumptions imply almost the same rate of growth of scientific employment during the next decade as has occurred in the years 1956–59, and the methods by which the estimates have been built up should command much readier acceptance of the conclusions, particularly in the present circumstances, than would have followed a simple projection of an existing trend Indeed, it might be argued that this continued growth in scientific employment is an essential factor if Britain is to hold her place in the world's markets, independently of whether or not she enters the European Common Market, and not to decline, with all that that implies for her economic future and the standard of living of her citizens.

The conclusion that by 1965 the supply and demand of scientific man-power should be in balance and that, thereafter, a surplus may exist contrasts almost startlingly with the crippling shortages of scientific man-power that have been experienced since the Second World War and with the findings of previous reports on this subject As the Manpower Committee points out, however, something can now be seen of the fruits of the efforts which have led to such a striking increase in our annual output of qualified scientific man-power since the War from 10,000 in 1955 to 16,500 in 1961 and a prospective 20,000 by 1965 and 30,000 in 1973 It is true that the balance is a statistical one, and that supply and demand in individual disciplines, of which mathematics may be instanced as the most important example, cannot be so easily equated Nevertheless, the Statistics Committee found no adequate basis for making separate estimates of the supply or demand for particular kinds of scientist or technologist, and the Manpower Committee recognizes that there may well be important differences in the factors which govern the prospects of employment between the specialized technologist and the engineer with a general training, and between technologists as a group and scientists, and that these problems remain to be examined

In the view of the Committee on Scientific Manpower, the possibility of a surplus of scientists over immediate demands for employment should be welcomed It should make possible a rational—as opposed to an emergency—use of the scientific disciplines, and it should mean that at long last Britain would have a supply of qualified man-power with a scientific training for management, administration and the professions generally in addition to those who up to the present have been drawn inevitably into vocational employment The Committee does not doubt that scientific education will adapt itself to this new prospect, and that, just as only a proportion of those trained in the classics and history have expected to find employment in their own fields of study, an increasing proportion of those trained in specialized scientific disciplines will obtain employment outside them

The Committee considers that both science and the nation will benefit from this adjustment and it believes that the universities are already thinking along these lines If the Committee's confidence is to prove well founded here, it is certainly essential that the universities should not only think constructively but also be ready to act vigorously before the expected surplus arises Modifications in the training of chemists and physicists such as have already been suggested from within the universities or by professional institutions could go far to correct the narrowness and rigidity of training which limit the employability of a scientist or technologist trained in a particular discipline; and too much care cannot be taken to ensure that neither the scientist nor the technologist is too narrowly trained Colleges of technology, as well as the universities, may well have to resist very firmly pressure to give training in techniques which should properly be acquired in industrial or professional practice, and in this context the growing stress being laid on a broad general education is to be welcomed

The report, therefore, should administer a wholesome check to the tendency to excessive or premature specialization; but if waste of highly skilled man-power is to be avoided, there are other matters that require attention The Manpower Committee is fully aware of the danger of complacency, and that the balancing of supply and demand is a relative, not an absolute, situation The size of the reserves of ability on which Britain can draw, the problem of quality and the appropriate claims of disciplines in arts as well as science have to be considered, moreover, the calculations in the report do not cover medical, dental, agricultural or veterinary qualifications, the specialized technologies or the social sciences All these must be considered in any national review, and will involve questions of transfer which may not be easy to forecast Fully as important, however, are major questions concerning the relations, both in industry and in research, of qualified man-power and the technicians and other skilled man-power on which efficient use of professional man-power depends

A report from the University Grants Committee, issued almost simultaneously with the report of the Committee on Scientific Manpower, directs attention to the low ratios of technicians to research workers in the universities, which is regarded as below that necessary to ensure that the time of research workers is used most economically The Committee on Scientific Manpower hopes to examine this last issue more closely in the near future, but it is obvious that these questions of the conditions of service will not become any the less important if the nation experiences a surplus in place of a shortage of scientific man-power Further, while the adaptability of the scientist and technologist becomes more important, whether in fact he or she is used in a wider range of occupations depends equally on the willingness of the employer to experiment The scarcity of scientists and technologists in administrative appointments, for example, is not solely due to their reluctance to take up such posts It is just as much, and possibly more, due to the unwillingness of departments or firms to give such appointments to the scientist or technologist, to the persistent belief that a person trained in a scientific discipline is inherently unfit for such responsibilities, though on this point it should be noted that the estimated demand of 12,400 scientists in the central Government by 1970 depends on the assumption that they will be increasingly employed outside the scientific field No improvement in the general training of the scientist or technologist, or in the provision of opportunities for training for management, will avail while this prejudice persists

The clear warning this report gives of a probable surplus of scientists and technologists within the next decade should stimulate fresh endeavours to deal with this and numerous other factors which hinder the wise, widespread and efficient use of science and technology in the ordering of British national affairs.

VISION, WITH AND WITHOUT TEARS

The Eye and Its Function

By Dr R A Weale Pp vii + 209 (London. The Hatton Press, Ltd , 1960) 55*s* net

Anatomy and Histology of the Eye and Orbit in Domestic Animals

By Prof Jack H. Prince, Prof Charles D Diesem, Prof Irma Eglitis and Gordon L Ruskell Pp xi + 307. (Springfield, Ill , Charles C Thomas; Oxford: Blackwell Scientific Publications, 1960) 126*s*

The Structure of the Eye

Proceedings of the Symposium held April 11–13 during the Seventh International Congress of Anatomists, New York Edited by George K Smelser Pp xv + 570 (New York : Academic Press, Inc ; London: Academic Press, Inc (London), Ltd , 1961) 107*s* 6*d*

THREE additions have recently been made to the already long list of books on the eye, and these all to a remarkable degree accentuate the structural aspects, but from very different points of view.

The first, *The Eye and its Function*, is addressed to "those who use the eye and wish to read about its function" Since all who are not blind use the eye for various purposes, the book is apparently intended for all those who wish to read about the eye This category may obviously include all classes, from the film star interested in the practical use of the ocular muscles and the lacrimal glands, to the medical student, the research physiologist, the experimental psychologist, and even the greatest expert in ophthalmology Naturally enough, the book reflects this lack of decision as to who are its potential readers and is a curious mixture of the commonplace, the significant and the abstruse For the completely uninitiated there is probably too much technical information and knowledge required for the text to be easily comprehensible For the expert in any one branch of the subject, the treatment is often inadequate and sacrifices of accuracy have sometimes been made in the interests of brevity or of an apparent, though possibly deceptive, simplicity. There is, however, a wealth of general information about the eye and its function to be gleaned from perusal of the contents Both general biologists and medical students should find the book helpful and stimulating In places, the English could be improved (for example, the legend for Fig. 9 3) and references to original sources are sometimes inadequate

The second book, *Anatomy and Histology of the Eye and Orbit in Domestic Animals*, is clearly addressed to the veterinary profession, though the first five chapters, which give a good general picture of the eye and its associated structures, are based largely on human studies The emphasis of the book is essentially on structure rather than on function, and special attention is paid to information on those features which are peculiar to the particular species investigated The gross anatomy is, in general, better treated than the histology and cytology Retinal structure. for example, is somewhat superficially treated.

The third, *The Structure of the Eye*, is a book for the specialists in cytology and vision It incorporates the proceedings of a symposium held in New York in April 1960, and, unlike many books published after similar symposia, is very informative and has both depth and breadth. Structure here includes mostly the molecular, cytological and histological, gross anatomy being scarcely mentioned. The book is an amazing compendium of the main new advances made in a very fertile field of research during the past decade or so. It includes excellent chapters on the microstructure, properties and functions of the photoreceptors, on the pigment epithelium, on the development, formation and properties of the lens, the vitreous body, the ciliary bodies and on the cornea. It is a book which is full of recently acquired information on all these topics and is thus of the greatest importance to all those who study the physiology of the eye and its visual functions, whatever their particular interest may be. Moreover, for cytologists in general, the problems of cellular structure and function which are discussed in this book must have an appeal far beyond the visual orbit. Indeed the structural basis for much general physiology is analysed within the pages of this book. The symposium was clearly very well organized and the fruit of it is well blended into a very digestible compôte. The book is very well produced and illustrated; it forms a valuable contribution to the literature on vision. E. N. WILLMER

LIGHT AND LIFE

A Symposium on Light and Life

Edited by William D. McElroy and Bentley Glass. (Sponsored by the McCollum-Pratt Institute of the Johns Hopkins University with support from the National Science Foundation.) Pp. xii+924. (Baltimore, Md.: The Johns Hopkins Press; London: Oxford University Press, 1961.) 120s. net.

THIS volume is the most recent addition to a series of symposia which have received acclaim for the authoritative character of the contributions and the breadth of the treatment which successive topics have received. The debt which biochemists and biologists owe them is evinced by the frequency with which they are quoted in the research literature, for they have provided both an accurate and comprehensive historical record of major fields of active research and a stimulus to further work and thought. A reviewer is compelled to appraise this recent addition to the series by the standards which its predecessors have set.

Against such a record, this volume appears somewhat disappointing. Difficulty is encountered at the outset in that the subject appears to have no natural unity. Three groups of biological phenomena are discussed: the emission of light in bioluminescence, the utilization of light in photosynthesis, and the photosensitization of certain processes, including phototropism, photoperiodism and vision. Some correlation between these diverse activities might be expected in the physicochemical character of their primary reactions and the molecular changes associated with light absorption or emission, but at this stage the gap between our knowledge of the biological and chemical features is so wide that the two groups become almost autonomous, and individual papers even within sections can appear little related to any other. Our ignorance is too great; our knowledge cannot provide the cement to hold them together, and imagination has yet to come to our aid.

The arrangement of the contributions is rational enough. The response of molecules to photo-excitation is discussed first, with treatment of the excited states of simple molecules, the nature and importance of the biologically interesting $n \rightarrow \pi^*$ transition, and the triplet state. The general conclusions are then applied to the specific properties of biologically important molecules, including proteins, and pyridine and flavin nucleotide enzymes. This section, however, deals with the application of spectral data to structural and kinetic problems, rather than the biochemical consequences of the excitation of these molecules.

Chemical and biological aspects are wedded most effectively in the section on bioluminescence. Here, the chemistry of luminescence in the porphyrin-catalysed decomposition of peroxides and of the luminol reaction is described and discussed before proceeding to the various bioluminescence phenomena, ranging from the firefly and *Cypridina* to fungi, the dinoflagellates and the sea anemone. The comprehensive paper on firefly luminescence by McElroy and Seliger is particularly valuable.

Extended discussions on photosynthesis have now become so frequent that contributors must experience difficulty in sensing positive achievement year by year; the same arguments can be rehearsed too often before the same public. Certainly, much that appears here has already been published. Three long articles—on the spectral character of chloroplast pigments, the immediate consequences of chlorophyll excitation, and the biochemistry of generation of adenosine triphosphate in chloroplasts and bacterial chromatophores—dominate this section, which gains interest from the papers discussing electron spin resonance studies, and the likelihood and consequences of more than one primary photochemical reaction sensitized by different pigments. Some of the other contributions are rather slender and appear to deal with reactions too remote from the primary action of light to justify inclusion in a symposium under this title.

The final section deals with photosensitized phenomena in biology, in which both the initial activation and the amplification necessary to achieve the response, have to be considered. Phototropic curvatures and photoperiodic responses have still not progressed far beyond the descriptive stage, and critical experiments which contribute to an appreciation of their mechanisms have yet to be carried out. The contributions by Rushton and by Wald on the molecular character of the excitation process in vision and its consequences set a pattern for the treatment; two interesting but inconclusive papers on colour vision in insects and goldfish conclude the symposium.

The discussions after lectures, with their mixture of information, wit, boorishness and irrelevancy, have been included, though it is regrettable that the comments on some papers have been recorded before their delivery (or publication). The whole symposium is summarized *in extenso* by Bentley Glass, usually accurately and informatively, so that those not minded to read each paper can obtain the gist with less effort.

Even though the organization and content of the papers in this volume may be subject to some criticism, any who read this volume thoroughly cannot fail to be impressed by the range and variety of the information and to be stimulated to integrate it each after his own taste. V. S. BUTT

SELECTED STUDIES IN CHEMICAL KINETICS

Selected Studies in Chemical Kinetics
By Prof Farrington Daniels (Thirty-fifth Annual Priestley Lectures) Pp vi+123 (University Park, Penn. Phi Lamda Upsilon and the Department of Chemistry, Pennsylvania State University, 1961) 2 75 dollars

WHEN considering a new plant for the chemical process industries the three important questions that must be answered are how big, how much and when In approaching the problem of how big, knowledge of the rates of reaction or kinetics and the conditions of equilibrium are two vital tools of design Prof Daniels, in the 35th Priestley Lectures, sets out to give us an indication of the progress made and the general techniques available in handling the problem of kinetics

The general arrangement of these lectures is to give initially an outline of the principles of kinetics and the relation of this subject to other sciences This is followed up with a number of illustrations of work in this field primarily conducted by Prof Daniels and his associates It is by these examples that Prof Daniels succeeds in indicating the methods of attack that are possible and at the same time makes it clear how difficult this subject really is Kinetics, as understood here, deals primarily with the time and mechanism of a chemical reaction It includes such subjects as catalysis, photochemistry and spectroscopy It is important to realize that when two or more compounds react they give rise to several different products but the one with the largest yield is that produced by the fastest reaction It is becoming both a science and an art to adjust the temperature, concentration, catalyst and solvent so as to favour the desired reaction to the maximum extent For industrial purposes all reactions must be made to proceed fast enough to be economically feasible, and this is often a vital problem At the same time, although kinetics is essential in industrial design it also offers an intellectual challenge, as, in the words of Prof Daniels, "We have to make the molecules do our bidding"

The first main illustrations cover the work on the decomposition of nitrogen pentoxide Here it is interesting to read how the mechanism in this reaction has proved a considerable puzzle and the sorting out of this complex reaction has provided many opportunities for developing new techniques in experimental work The second illustration refers to the oxidation of nitric oxide, again a reaction of enormous chemical importance where the slowness of the reaction has presented problems in engineering design This is a particularly interesting reaction as it is not only termolecular, which is relatively rare, but also has a negative temperature coefficient

Other reactions discussed in some detail are the decomposition of nitric oxide and the Wisconsin process for fixation of atmospheric nitrogen The account of the work is interesting both in terms of physical chemistry and chemical engineering, where the application of sudden chilling of the gases by pebble beds is relatively new and remarkably effective

In the final lecture, Prof Daniels refers to the kinetics of reactions in solution and in a solvent He offers some useful information on some of the latest techniques used in studying these reactions, and his chapters on photo-kinetics and photo-chemistry are very interesting reading

This set of lectures is welcome as it provides an extremely valuable account of the importance of kinetics in tackling industrial problems where design of reactors has proved more difficult than the design of much of the equipment used for physical separation The lectures are of value to chemists and to chemical engineers J M COULSON

MATHEMATICAL THEORY OF NUTRITIONAL RELATIONSHIPS OF FISHES

Experimental Ecology of the Feeding of Fishes
By Prof V S Ivlev Translated from the Russian by Douglas Scott Pp viii+302 (New Haven, Conn, and London Yale University Press, 1961.) 7 50 dollars, 60s

THIS book, by a leading Soviet experimental ecologist, constitutes an important contribution to the nutritional ecology of fishes Many factors govern the rate of feeding of a fish, and also its choice of particular foods in selective feeding They include the total density of food, its aggregation, the partial densities of its separate components, the protection afforded to the prey by refuges or by mobility, the amount of contact with other fishes, the formation of habits of grazing on particular foods These factors influence the fish simultaneously, so that the analysis of any one of them under natural conditions is practically impossible In a long series of carefully controlled laboratory experiments, Prof Ivlev has been able to isolate the factors one by one, and to investigate the influence exerted by each acting alone Then, by means of a graded series of recombinations of the factors, he builds up a system of formal equations which represent not only the quantitative changes in the diet of the fish but the qualitative ones as well, very closely

Ivlev's approach is essentially biophysical He has modified the classical approach of Lotka and Volterra to the question of the effects of the concentration of the food on the rate of feeding, by introducing a factor which inhibits unrestricted increase in the rate of feeding at higher food concentrations This leads him to apply the monomolecular or inverse exponential equation This equation satisfies the experimental data very closely

A large part of the book is concerned with the expression of selective feeding Here Ivlev adopts a new type of coefficient of selectivity, which works well in a variety of situations It can also be applied to data suitably collected under natural conditions

Ivlev is the first to have published such an experimental analysis of these problems, I believe that the publication of the work in English will stimulate many new investigations into outstanding problems in this field It may be noted in passing that all the experimental animals used were freshwater fishes, as regards marine animals, the field is wide open

Considering the importance of the book, the standard of translation is regrettably poor The Yale edition contains the most shocking mistranslations, there are misleading blunders on every page, while the text has scarcely been rendered into good English. The author's style is laconic and it is difficult sometimes to find apt ways of rendering it, this is no excuse for writing the first thing that comes to mind Editing plays no small part in producing a work of this nature, manifestly, this translation has not been edited at any stage For the garbled result, the blame rests equally on Mr Scott and the Yale University Press It certainly does no credit to either

In view of these latter considerations it might be thought that the stipulated price is inordinately high L BIRKETT

PROGRESS IN CANCER RESEARCH

Cancer Progress, 1960

Edited by Ronald W Raven Pp xv+242+16 (London Butterworth and Co (Publishers), Ltd, 1960) 60*s*.

ONE of the problems of the organization of research, particularly in the cancer field, is to steer between the Scylla of lack of co-ordination and the Charybdis of too much When the ship sails too near the latter, senior workers find themselves spending almost all their time attending committees and meetings and writing review articles, while junior workers, who are in any event forced to specialize too early, rarely find the time to read review articles outside their own subject Regrettably, it is with increasing frequency that we see the same data presented in more than one paper, and worse still, the same fields of investigation reviewed more than once by the same individual

Against this background the editor, Mr R W Raven, and his advisers, are most certainly to be congratulated both on their choice of well-defined subjects and on their selection of authors The brevity of most of the contributions, and the fact that many of them are presented as sequels to chapters in the parent book, *Cancer*, gives this volume an entirely different form and function from *Advances in Cancer Research* or the *Year Book of Cancer*

As one would expect, the standard of contributions varies considerably Articles on tumour viruses (R J C Harris), bone marrow replacement (H E M Kay and P C Koller), circulating cancer cells (J W Stewart), carcinomatous neuropathies (D S Russell), carcinoid tumours (P J D Snow), industrial causes of cancer of lung, nose and paranasal sinuses (P L Bidstrup), the effects of radiation on the normal lung (T J Deeley) and the effect of oxygen in radiotherapy (I Churchill-Davidson) are among the many interesting and useful contributions

Russian authors (N I Lazarev and L F Larionov) contributed three of the five chapters in the section on chemotherapy In one of these it is cogently, though somewhat naïvely, argued that both the carcinogenic and the anti-tumour effects of hormones rest on their physiological activities The last chapter in this section (D A G Galton) corrects any impression given by the previous four, that chemotherapy almost holds the key to the cure of cancer

In an interesting article on cancer in the South African Bantu, A G Oettlé describes the enormous difficulties in obtaining a clear picture of the incidence of cancer in a primitive society This is a timely warning to those who criticize civilized practice on the grounds that cancer is infrequent among communities living a more 'natural' life With regard to treating a member of such a community, he writes, "His fears and prejudices, his misunderstandings and his phobias have all to be considered in the therapy of the whole man". Such is equally true treatment of less-primitive men

Among the least pleasing features of the book are the fairly small size of the type and the narrow width of the margins it is hoped that this form of economy will be dispensed with in future volumes

MEDICINE AND INSECT PARASITES

Medical Entomology

By Dr William B Herms and Dr Maurice T James Fifth Edition Pp xi+616 (New York and London The Macmillan Co, New York, 1961) 87*s* 6*d*

THE fourth edition, by the senior author only, was published in 1950 This fifth edition is the work of Prof M T James, who has clearly, with much care and endeavour and with considerable success, produced a book several pages shorter than its predecessor yet combining a good deal of its original format and material with new matter This includes both new text, which brings the book more up to date in many aspects of the subject, and new illustrations, which enhance the pictorial presentation of its topics As noted in the preface, veterinary entomology has been pruned considerably and the sub-title of the fourth edition, implying this aspect, has been dropped Nevertheless, sufficient remains to serve the medical man who might well, in rural communities, have to think broadly, especially of mites and ticks, œstrids and biting flies

In general, trends in control are well revised regarding contact insecticides and repellents Malaria is discussed, with leading references, in terms of control and world eradication—for which the book observes a cautious optimism The mathematical approach to the epidemiology of malaria, as analysed by Macdonald, is indicated usefully and briefly Due elaboration is given to more recent discoveries on arthropod-borne virus diseases transmitted by mosquitoes and by ticks Revision of the housefly and its allies is commendable and, although the section on tsetse is barely altered, the reader is led to the newer important general works on this subject Nomenclature has usually been brought into line with recent authoritative works There are, of course, points of criticism Garnham is spelt Garman, there is no indication of the use of dieldrin for triatomid bugs; the section on loiasis makes no mention of the important ecological studies of this disease in the past decade, nor is the association of *Simulium* larvæ with crabs noted, there could be more about *Mansonia* mosquitoes

Of the several keys, some new, those referring only to American fauna (for example, mosquitoes, *Culicoides*) must have limited interest, but others (for example, on fleas, ticks and mites) will have wider utility It is difficult to see how, in a general work, such selection can be avoided

Many sections are simply reprinted, but much new information is included in the re-arrangement of chapters and within chapters, the new format providing much clearer printing of sectional headings The reader is assisted to main discussions of particular topics by bold-face page references in the index

This is a worthy successor to the four previous editions and should prove an informative and useful general work for the student, and teacher, of medical entomology D S BERTRAM

ADVANCES IN THE GENERATION AND USE OF VERY HIGH, CONTINUOUS MAGNETIC FIELDS

By Dr HENRY H KOLM

National Magnet Laboratory*, Massachusetts Institute of Technology, Cambridge, Massachusetts

A MAGNETIC field exerts four effects which make it useful as a research environment it produces a torque on a magnetic dipole, it exerts a force on a moving charge, a space-varying field exerts a force on a magnetic dipole, and finally a magnetic field varying with time exerts a force on a stationary charge

When a magnetic field is applied to the microscopic dipoles in various solids, such as paramagnetic salts for example, the dipoles do not simply become aligned with the field, for two reasons ordering is opposed by thermal motion which tends to preserve random orientation, in the second place, these magnetic dipoles also possess angular momentum and therefore tend to behave like gyroscopes, instead of aligning themselves with the direction of field, they precess around it at their precession frequency The alignment of dipoles against thermal agitation produces reversible heating, a mechanism which is utilized in achieving the lowest possible temperatures The precession frequency of gyroscopic dipoles is observable as absorption in the microwave or infra-red frequency-range, and provides valuable information concerning electronic band structure, crystalline magnetic fields, etc

The second effect, the force exerted on moving charges, forms the basis of all particle accelerators in which a magnetic field is used to confine the accelerated particles within circular orbits This confining force is loss-less, since a magnetic force always acts perpendicularly to the direction of motion Magnetic fields can therefore also be used to confine very hot plasma, or ionized gases, by preventing the energetic particles from ever giving up their energy to the material walls of a physical container They are also a valuable tool in producing a measurable curvature in the trajectory of high-energy particles. Space-varying fields, or fields with a high gradient, are used to measure magnetic susceptibilities, and also to analyse beams in experiments with atomic beams

Finally, the force produced on a stationary charge by a field varying with time simply represents the law of electromagnetic induction, which forms the basis of electric motors and generators, as well as radio propagation The effect is also used experimentally for accelerating particles in circular accelerators and for heating plasmas in fusion reactors. Thus we see that a magnetic field is required for producing the lowest as well as the highest attainable temperatures Both these applications require magnetic fields of reasonably large volume, while solid-state research requires primarily fields of high intensity but modest volume

Laboratory magnetic fields are conventionally produced by iron electromagnets which consist of an iron frame, one or two legs of which are surrounded by coils The field induced in the iron is approximately 1,000 times as intense as the field which would be produced by the same coils in the absence of iron, and it is made accessible for experimentation by introducing a gap or break in the iron frame This method fails if a long or prolate field volume is required, because an excessively long gap in the iron core eliminates the effect of the iron, the method also fails if the required field intensity is higher than the value at which iron becomes saturated magnetically In both these cases it is then necessary to generate the field without the use of iron, or with only incidental assistance from iron The elimination of iron requires approximately 1,000 times as much current, which makes the generation of very high continuous fields a difficult and costly undertaking Although thermodynamically it should require no expenditure of power to maintain a magnetic field, it is an ironical fact that this is the only process we perform with zero efficiency It is necessary to remove all the power supplied to a magnetic coil in the form of heat Recent progress in the development of superconductors capable of withstanding substantial currents and magnetic fields suggests that we may actually be on the verge of eliminating this thermodynamic incongruity

It is much simpler to produce high fields for very short periods of time by using stored energy and relying on thermal inertia to keep the coils from melting Work with pulsed fields was pioneered at the University of Cambridge in 1927 by Kapitza[1], who achieved 500 kilogauss for periods of milliseconds by using energy stored in batteries and in rotating generators More recently, the technique has been advanced into the megagauss range by the use of capacitor energy-storage and improved coil design[2,3] and by harnessing explosive energy[4,5]

The earliest effort at generating very high continuous fields was undertaken at the Massachusetts Institute of Technology in 1936 by Bitter[6] It was stimulated by the need for more resolution in optical measurements of the Zeeman effect during the pioneering days of spectroscopy, and by the need for achieving lower temperatures by adiabatic demagnetization The magnets developed by Bitter are helices formed by stacking copper disks with a radial cut, interleaved with sheets of insulation Neighbouring copper disks overlap at their radial cuts so as to establish pressure contact when the entire stack is compressed The copper is cooled by direct contact with water, which flows through some six hundred small holes passing through the entire stack in the axial direction. Bitter succeeded in generating 100 kilogauss in a helix of this sort having a 1-in bore and an outside diameter of 16 in, by supplying it with 1 7 MW (10,000 amp at 170 V.) of power and 800 gallons per min. of cooling water Similar installations and magnets have been built since in several laboratories

---

* Supported by the Air Force through the Air Force Office of Scientific Research

throughout the world, but for more than twenty years no effort was made to advance beyond the 100-kilogauss level This is due largely to the fact that interest in obtaining higher continuous fields was relatively mild and de-centralized among so many widely separated scientists that no concerted effort of the required magnitude was made

The situation changed quite suddenly during recent years with the advent of several vital experiments which use magnetic fields as a tool for investigating the nature of charge carriers and their energy-band structure in solids. The most prominent among these is the observation of 'cyclotron resonance', a phenomenon based on the circumstance that all particles (or holes) having the same charge-to-mass ratio will orbit around the flux lines of an applied, continuous magnetic field at the same frequency, regardless of their individual energy faster particles will simply describe larger orbits than slower ones This coherent behaviour of statistically distributed but identical particles manifests itself in resonance absorption at a frequency varying with the applied magnetic field and situated in the short microwave region when the magnetic field is in the range 20–30 kilogauss These experiments[7] could only be performed in crystals of great perfection (originally germanium and silicon) in which the mean free path of charge carriers is large compared with the cyclotron orbits, because otherwise scattering by collision occurs so frequently as to mask the resonance In order to observe cyclotron resonance in materials of less perfection, it was clearly necessary to increase the frequency from the shortest usable microwave to at least the longest usable infra-red Unfortunately, this made it necessary to increase the magnetic field from the 30 kilogauss range, readily available in iron electromagnets, to beyond the 100-kilogauss range The first attempt to do so was made by the Lincoln Laboratory group in 1955 (refs 8 and 9), using a pulsed magnet capable of up to 750-kilogauss pulses of 120 μsec duration, in a hole 3/16 in. in diameter It was energized by an underdamped (that is, oscillatory) capacitor discharge so as to minimize resistance losses and permit the use of coils made of alloys having greater strength but also higher resistance than copper Problems involved in the rapid detection of changes in infra-red transmission or reflexion presented some difficulties and limited the accuracy of measurements, but valuable exploratory results were obtained for InSb, InAs and Bi Quite incidentally, certain oscillatory effects were also observed which were eventually resolved and studied in continuous fields.

This early experience emphasized both the importance of working in higher fields and the inadequacy of pulsed fields, particularly in the farther infra-red region, where the decline in both source intensity and detector sensitivity requires long measurements It appeared imperative for a number of other good reasons as well that a new attempt be made to advance the art of generating very high continuous fields beyond the point at which it had remained for such a long time

It was in this spirit that, with several other members of the Lincoln Laboratory Solid State Division at the Massachusetts Institute of Technology, notably Benjamin Lax, Donald Stevenson and D Bruce Montgomery, I joined forces with Francis Bitter for a renewed attack on the old problem Three efforts were launched at about the same time first, the problem of designing high-performance solenoids was re-examined in the light of all available information; secondly, a proposal was made and presented to a number of Government agencies and leading scientists suggesting that a new laboratory be built for the purpose of making generally available for research the highest continuous magnetic fields which can be generated at the present state of the art, thirdly, communication was established among scientists concerned with the generation and use of such fields I propose to report briefly the progress made along these three lines during the first three years

The problem of designing solenoid magnets is best characterized in terms of a relation discussed extensively by Bitter, namely

$$H = G\,(W\lambda/r\rho)^{1/2}$$

where H is the field at the centre in gauss, W the power dissipated in watts, λ the 'space factor' or fraction of solenoid volume occupied by conductor (as compared with insulator and cooling channels), ρ is the resistivity at operating temperature, r the inner radius in cm, and G is a geometry factor (the 'Fabry factor') which characterizes the current distribution; this factor is 0·179 for a uniformly wound solenoid of optimum dimensions and about 0·209 for a helix such as the Bitter magnets, in which the current distribution is highest near the centre and falls off inversely with the radius When generating fields up to about 200 kilogauss, it is possible to maximize G by selecting the best realizable current distribution but beyond this point it is necessary to depart from the optimum distribution in order to prevent mechanical failure of the windings near the centre The space factor and resistivity must be considered together, since they are both governed by cooling, the former by the amount of cooling area required and the latter by operating temperature. Operation at cryogenic temperatures might appear attractive at first sight, but unfortunately as the temperature is lowered the required cooling area increases much more rapidly than the resistivity decreases, so that magnets become progressively inefficient Only if fields of very large volume are required or if operation is to be brief and infrequent do the economic factors favour cryogenic cooling Water offers considerable advantages even under conservative transfer-rates, say, 200 W/cm^2, if local boiling in sub-cooled water is permitted, it has been found possible to transfer as much as 5,000 W/cm^2, a rate which exceeds the rate of heat transfer at the surface of the Sun After verifying experimentally that transfer-rates of this order of magnitude are indeed feasible, and that they can be maintained with stability in very small channels (about a quarter millimetre thick), we undertook our first concrete task, that of building a magnet which would produce a higher field than the old Bitter magnets with the same amount of power It was intended not only as a research tool for immediate use but also primarily as a means for exploring new solenoid structures and new levels of performance

Since the helical structure used in the Bitter magnets does not lend itself to reduction of size without loss of heat transfer area, we selected a tape-wound spiral structure with funnelled ends for optimized current distribution Successive windings are separated by ribs which are aligned along radii like spokes of a wheel so as to transmit the radial outward forces to a strong confining envelope Cooling is achieved by axial flow through the channels between these

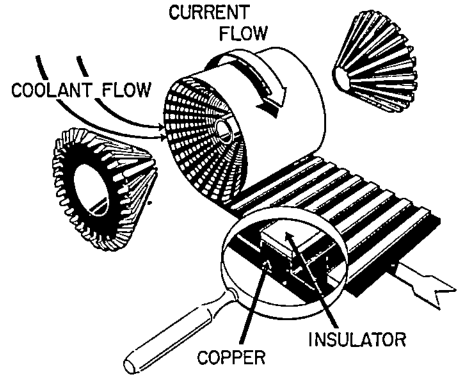

Fig. 1. Principle of the Kolm solenoid

ribs, and the ribs themselves consist largely of conductor with a minimum of insulation so as to reduce the loss of conductor volume and reduce the heat generation in uncooled portions of the tape. This structure provides such an enormous heat-transfer area that a helix of ½-in. calibre, 3-in. outside diameter and 2-in. average length is capable in principle of dissipating the entire available power of 1·7 MW. In practice, it proved impossible to maintain adequate flow, and the first two solenoids failed at somewhat less than half the power. On the basis of this experience, it was then decided to build a solenoid of twice the size (Fig. 1). Since impedance match to the same generators must be maintained, tape thickness remains invariant under the scaling. This increases the number of necessary slots and ribs to such an extent as to make manual fabrication impractical. The third solenoid was therefore constructed by the High Voltage Engineering Corporation on a semi-automatic jig built especially for the purpose. After two unsuccessful attempts and several modifications in materials, technique and design, a solenoid was completed and installed in its housing (Fig. 2). It generated 126 kilogauss at a power consumption of 1·88 MW. The test occurred in mid-summer, when operation is limited by the high temperature of the primary cooling water from the Charles River; in winter it will probably be possible to increase the power sufficiently to generate more than 130 kilogauss.

The second phase of the programme, construction of a new laboratory, has also been making satisfactory progress. The original proposal was favourably received, and by the time funds were provided through the Air Force Office of Scientific Research, initial studies had been completed and the major decisions had been made. It will comprise essentially a power plant of four motor-generator sets capable of supplying 8 MW of d.c. power continuously, 12 MW for a 15-min period, and up to 32 MW for a 2-sec period by the use of energy stored in flywheels. There will be ten cells or laboratories in which this power can be used, with space for expansion, and about 10^5 sq. ft. of area for supporting shops and laboratories. The generators will be separately controllable, so that four magnets can be operated simultaneously at 2 MW. each. The laboratory is expected to do for magnetic field research what laboratories like Brookhaven, for example, have done for nuclear physics. It will provide continuous fields up to about 250 kilogauss for visiting and resident scientists working in a number of different fields and also serve as a centre for advancing the art of magnet design. Construction of the laboratory is under the supervision of Prof. F. Bitter, and Dr. B. Lax will be its director. A broadly representative committee of prominent scientists is to guide all major policy decisions.

The third effort was first aimed at collecting and filing the sort of information on magnet design and performance data which are rarely if ever considered worth publishing. It began with a co-operative undertaking by a group of interested persons known as the "Magnet Society", and continues in the form of a punched card information file kept up by the staff of the new magnet laboratory. It is hoped that such information will ultimately be circulated in the form of periodical technical reports on magnet design and related subjects.

While working on the plans for the new laboratory, our group felt an increasing urge to discuss the project with a number of other scientists who might have occasion to use it. Since a new division of science, that of high magnetic-field research, was about to be born, it seemed logical to start things off with an international conference on the subject. The Air Force again generously agreed to provide sponsorship, and the date was set for November 1–4, 1961. Originally it was felt that this might coincide with the opening of the new laboratory, but as things turned out it will more nearly commemorate the ground-breaking. Papers to be presented at the conference will deal with the generation of high magnetic fields, as well as their use in plasma (ionized gas) physics, nuclear physics, solid-state physics and biology. Biological effects of magnetic fields have only recently attracted much attention, and the conference will provide the first opportunity for workers in this field to meet.

One cannot help but recall a similar conference in the field of low-temperature physics held in the Massachusetts Institute in 1949. It was originally intended to celebrate a great contribution to the field, namely, the invention of Prof. Collins's helium liquefier, but has since become a biennial event of great value. We

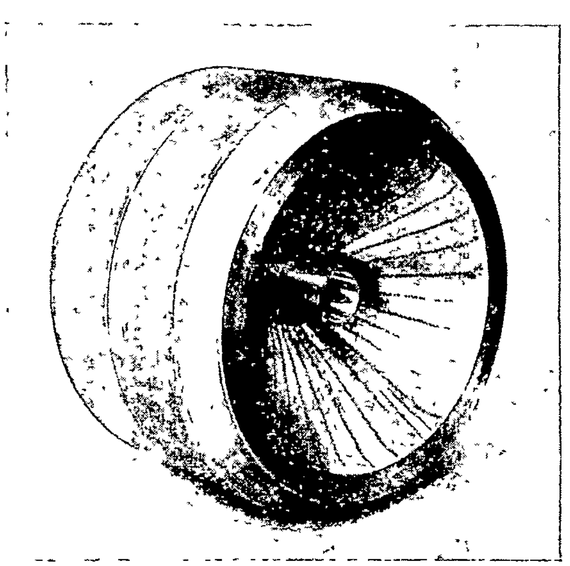

Fig. 2. Core of the new solenoid which generates 126 kilogauss at a power consumption of 1·88 MW. Calibre of the barrel is 1 in., outside diameter of the tape winding is 6 in. 300 gallons per min. of cooling water are pumped through the small channels which are aligned like the spokes of a wheel

sincerely hope that the high-magnetic field conference is destined to comparable success Like most divisions of science based on experimental difficulty, both cryogenics and magnetogenics are probably doomed to ultimate absorption into the more legitimate disciplines As in the case of cryogenics, however, high-magnetic field research will first experience a golden age of contributing a great many stimulating problems

TRAINING OF INDUSTRIAL FOOD SCIENTISTS AND TECHNOLOGISTS

THE "Training of Industrial Food Scientists and Technologists in the United Kingdom" was discussed on September 5 by Section B (Chemistry) of the British Association for the Advancement of Science, meeting at Norwich

Britain's war-time food problems drew sharp attention to the practical importance of the application of scientific knowledge to the processing and distribution of food. Likewise difficulties in obtaining technologists skilled in this field of work became apparent, and to meet this need the then Ministry of Food set up a working party in 1948 to study means of training A direct result of these endeavours was the establishment of the National College of Food Technology in London and the introduction of courses in food science at the Royal College of Science and Technology in Glasgow Although these centres have flourished, it has recently become clear that their joint efforts are insufficient to meet the rising demand This discussion at the British Association was therefore particularly appropriate in timing and content

Sir Herbert Broadley (U N International Children's Emergency Fund) dealt with international aspects of the problem in his opening paper His theme, which was to be emphasized by subsequent speakers, was the opportunity open to the United Kingdom to assist the under-developed countries in a realistic way by placing our technological and scientific resources at their disposal In the field of food science and technology, great needs exist, and while much has already been done, the shortage of suitable experts remains as a limiting factor which cannot be resolved on a short-term basis Not only are experts needed in the field to tackle the most urgent problems, but training facilities are also required in the United Kingdom for overseas students Only very limited numbers of overseas nationals have been able to obtain such training partly because of lack of places and partly because of the limited research being undertaken in Britain on food problems of special importance to the under-developed countries One of the major malnutrition problems is associated with shortages of protein foodstuffs, and increasingly the international agencies are forced to seek help in this field from the United States There is therefore a great opportunity for the universities and especially for the new universities of Britain to make a contribution in this field

Dr J S Mounfield (principal of the National College of Food Technology) analysed the difference in function of the food scientist and the food technologist and emphasized the importance of integration with industry in the training of the technologist While it is true that the food technologist requires a rather less intensive knowledge than the food scientist of any single basic discipline such as chemistry, physics or biology, he must nevertheless be given some training in engineering and management to help him to solve the problems of large-scale processing

Dr Mounfield quoted a survey carried out about two years ago which suggested that the United Kingdom's needs for trained food scientists and technologists were between 150 and 250 per annum Compared with these numbers, the present output is very small In these circumstances, it is difficult to see how we can make more than a token contribution to the training of students from under-developed countries Furthermore, it is clear from applications received at the National College that inadequate basic scientific training in some countries denies students the opportunity to profit from facilities which can be offered here He proposed that special qualifying courses be organized in the United Kingdom to enable such students to reach the required entrance standards The admissions problem was complex, and to increase the effectiveness of existing facilities for study he recommended the formation of a committee to foster co-operative effort between the research associations, the food industry and the education authorities

Prof J Hawthorn (professor of food science, Royal College of Science and Technology, Glasgow) began by considering the educational principles governing the training of food scientists as opposed to food technologists and emphasized the importance of the basic disciplines of physics, chemistry, biochemistry and microbiology in the development of the student's thought He reported the first stage of a survey being carried out by his own department on opportunities for graduates in food science, and estimated the apparent annual demand of the United Kingdom at between 150 and 250 per annum, thus agreeing with Dr Mounfield's estimate, which had been obtained independently This apparent demand, however, is almost certainly less than the real need and even the apparent demand is far in excess of the numbers of graduates actually produced He then pointed out that the Universities of Nottingham and Reading have now followed the example of Glasgow and would introduce degree studies in this subject as from 1961 The University of Leeds would follow in 1962

Dr J W Corran (chief chemist of J and J Colman, Ltd) then opened the discussion by making a formal proposal to the meeting that it should recommend to the Council of the British Association that an *ad hoc* committee be formed to consider existing schemes for training food scientists and technologists, to suggest means of extending the available facilities, to consider whether the food research associations could contribute to such training schemes and to bring any recommendations to the notice of the appropriate overseas departments of the Government. He also suggested that the membership of such a committee should include both scientists associated with food science and also persons with experience of conditions overseas and in under-developed countries. After discussion, the proposal was adopted.

Perhaps the main impression left in the minds of those attending was the growing sense of urgency in this field of work, and the feeling that the United Kingdom could and should do more to assist the under-developed countries in their drive to raise the nutritional standards of their peoples. While it was comparatively easy to discuss training needs and facilities, real progress would depend on the work of the professional teachers who would be concerned with those essential but tiresome details of entrance qualifications, standards and course structures. The root of the difficulties lay not merely in the availability of money to be spent in developing such facilities but also in the differences in educational standards between the under-developed countries and the United Kingdom.

J. HAWTHORN

INTERACTION OF WEST FORD NEEDLES WITH EARTH'S MAGNETOSPHERE

By PROF. S. F. SINGER
Department of Physics, University of Maryland

W. E. MORROW[1], of the Lincoln Laboratory of the Massachusetts Institute of Technology, has suggested the use of a new method for intercontinental communication. It is based on the use of belts of orbiting dipoles which act as a scattering medium for microwaves. This technique could have significant advantages over other satellite communication techniques. However, it has been pointed out by others, particularly observational astronomers, that this operational project labelled West Ford would have some undesirable side-effects on optical astronomy[2] and on radio astronomy[3]. This article is not concerned with these effects nor with communications and related topics[4]. Instead I shall examine in some detail certain aspects of the interaction of the West Ford medium with the exosphere, in particular the interaction of the electric charge, which the needles are certain to carry, with the ionized portion of the exosphere. I wish to point out the possibility of making unique observations which can help establish the important parameters of this interaction. Therefore, so far as possible, this article will give numerical predictions of orbit changes. In addition, a useful modification of the experiment is suggested.

Forces acting on Small Particles in Near Space

The unique properties of the orbiting dipoles arise from the fact that they are so small. They have, in fact, close to the largest area-to-mass ratio (50 cm^2/gm.) of any artificial satellite, and approach an area-to-mass ratio of small ($\sim 100\mu$) interplanetary dust particles. Hence we can apply to the West Ford medium an analysis used for interplanetary dust in the vicinity of Earth[5]. [See also p. 321 of this issue.]

The motion of a particle is determined by the forces which act on it. Within the region of Earth's exosphere (taken to extend out to about 10 Earth radii) the gravitational force of Earth predominates and will be orders of magnitude greater than other forces, even for small particles. However, there are three other forces which need to be taken into account, particularly for orbiting particles: (1) radiation pressure; (2) the Lorentz force produced by Earth's magnetic field; (3) Coulomb force produced by the interaction with the ionized exospheric gas.

(1) The radiation pressure force is chiefly due to solar radiation and, to a smaller extent, to the radiation scattered from and emitted by Earth. The dynamic effects of the radiation pressure force have been investigated by Jones and Shapiro[6]. The effects predicted for the West Ford medium are given in a paper by Morrow and MacLellan[4] and would indicate that the medium disperses at a certain rate; also that the change in eccentricity produced by a resonant phenomenon would be particularly strong for polar orbits at altitudes of 3,700 km.

(2) The Lorentz force acts perpendicular to the velocity vector of the particle. It will be most pronounced in the polar regions where the magnetic field is strong and always perpendicular to the velocity vector of the particle. Only one general statement may be made about the effects of the Lorentz force: it cannot change the total energy of the particle. In other words, the semi-major axis of the orbit will remain constant, but the other parameters of the orbit may vary.

(3) The Coulomb (electrostatic) drag force has been shown to be one of the most important forces for particles moving in interplanetary space[7]. This electrostatic drag force acts generally between any charged body moving through a plasma and has therefore been also considered for the case of Earth satellites by various authors who, however, arrive at varying conclusions[8–13]. My view agrees most closely with that of Lehnert[8], who first showed that the Coulomb drag would not be particularly effective for Earth satellites of nominal dimensions.

The importance of the Coulomb force then hinges on two points: (a) the small size of the body; (b) the question of its charge. In general we may say that if the body were very much smaller than the Debye screening distance, then the question of the Coulomb drag should be investigated in detail. The dynamics of the charging situation was investigated by me, and I also discussed the competition between photoelectric emission and accretion of charge by ambipolar diffusion from the surrounding plasma. It was concluded that in interplanetary space dust particles would most likely be positively charged[7]. Whipple[14] has pointed out explicitly that the charge becomes less positive as one approaches Earth, and becomes negative in the ionosphere

Since the Coulomb drag produces a dissipation effect akin to friction, it will decrease the semi-major axis of the orbit continuously and eventually cause the particle to enter the dense atmosphere of Earth I am therefore particularly interested in investigating the effect of Coulomb drag on the particle's life-time

Analysis of the Coulomb Drag Force

For the purposes of discussion I shall adopt a treatment introduced by Chandrasekhar and Spitzer in which the orbiting particle will be referred to as the 'test particle' and the ions and electrons of the exosphere as the 'field particles' The drag deceleration is given by[15]

$$a_C = -A_D \left(\frac{m_1}{2kT_1}\right)\left(1 + \frac{m}{m_1}\right) G(x) \qquad (1)$$

where the subscript 1 always refers to the field particles,

$$x = (1\ 5)^{1\ 5}\, w/C_1$$

where $C_1 = (3kT_1/m_1)^{1/2}$, and is the root mean square velocity, and w is the test particle velocity ($\sim$ 5 km / sec)

$$G(x) = \frac{\varphi(x) - x\,\varphi'(x)}{2x^2}$$

$$\varphi(x) = 2\pi^{-1/2}\int_0^x \exp(-y^2)\,dy$$

$$A_D = 8\pi e^4 n_1 Z_1^2 Z^2 (\ln\Lambda)/m^2$$

$$\Lambda = 3(2Z\,Z_1\,e^3)^{-1}(k^3T_1{}^3/\pi\,n_1)^{1/2}$$

where n and Z denote particle concentration and charge, respectively, for the exosphere $Z_1 = 1$

With an exospheric temperature T_1 of 1,500° K, we obtain. $C_1 = 6\ 1$ km./sec for protons, $C_1 = 260$ km /sec for electrons Under these conditions $\ln\Lambda \sim 20$, $G(x) \sim 0\ 2$ for the field protons and less than 0·015 for field electrons Since the particle mass $m \gg m_1$, equation (1) reduces to

$$a_C = 1\ 23 \times 10^{-23}\, Z^2\, n_1/m \qquad (2)$$

In the derivation of equation (2) some approximations have been made, for example, the particle's velocity w was assumed constant and appropriate to a circular orbit at an altitude of 9,500 km No greater refinement appears necessary in view of the gross approximations which must be made in the calculation of the charge Z

Calculation of Electric Charge

The electric charge of the particle is given by its electric capacity multiplied by the potential of its surface For a conducting sphere of radius a cm ·

$$Z = 6\ 95 \times 10^6\, aV \qquad (3)$$

where V is measured in volts For a body of different shape the capacity must be calculated, in the absence of detailed data we will adopt a system of two spheres each with 'effective' radius of $1\ 5 \times 10^{-3}$ cm Thus for the West Ford needles, we take

$$Z \sim 2 \times 10^4\, V \qquad (4)$$

The calculation of the potential V also presents special problems since it depends on the position of the particle, and therefore in turn on the characteristics of the particle's orbit It also depends on the work function W and photoelectric yield γ of the particle material, its shape and its attitude towards the Sun As explained earlier, we calculate V in an analysis involving competition between the photoelectric effect and ambipolar diffusion[7] The ambient density above $\sim 1\ 5\ R_E$ (Earth radii) is given by Helliwell as

$$n_1 \sim 10^4\, r^{-3} \qquad (5)$$

where r is measured in terms of Earth radii

The photo-emission is determined by the ultraviolet spectrum of the Sun, that is, by N_ν (the photon flux per cm ²/sec with energy $h\nu \geqslant eV + W$). I assumed the relation $N_\nu = fV^{-\delta}$, where $f = 10^{19}$ and $\delta = 4$ On the basis of Hinteregger's measurements[16], a better set of values is

$$N_\nu = 2{\cdot}2 \times 10^{18}\, V^{-1.844}\ [\text{cm}^2\text{sec.}]^{-1} \qquad (6)$$

The equilibrium potential is given by ref 10

$$V_+ \sim +\,(\gamma f/n_e C_e)^{1/\delta} \qquad (7)$$

when the particle has a large positive potential and the ion current can be neglected In Earth's shadow, where photo-emission is negligible, the equilibrium potential is given by

$$V = -\,(kT_e/2e)\ln(m_i T_e/m_e T_i) \qquad (8)$$

In view of the uncertainties in γ, W, attitude and orbit orientation, I have decided to make some drastic approximations and represent the potential by·

$$V = 7{\cdot}5\,(r - 2) \qquad (9)$$

As can be seen, V varies from $-7\ 5$ V. in the F-layer to $+60$ V at 10 R_E Note that $V = 0$ at 2 R_E, the implication will be discussed later

It should perhaps be pointed out explicitly that another powerful charging process exists, namely, the high flux of fast electrons in the outer radiation belt, it is, however, quite localized and confined mainly to the vicinity of the lines of force which extend to 3–5 R_E in the plane of the magnetic equator. Its effect is to produce (or enhance) the negative charge (by accretion and secondary electron emission), this effect must be considered for orbits which intersect the outer radiation belt

By combining equations (2), (4), (5) and (9) we obtain for the Coulomb drag deceleration

$$a_C = \sim 3 \times 10^{-9}\,(r-2)^2\, r^{-3}/m$$

With the needle mass given[4] as 10^{-4} gm

$$a_C \sim 3 \times 10^{-5}\,(r-2)^2\, r^{-3}\ [\text{cm./sec}^2] \qquad (10)$$

This acceleration may be compared with the accelerations due to

(i) Radiation pressure

$$a_{RP} \sim \left(\frac{\text{solar constant}}{\text{speed of light}}\right)\left(\frac{50\ \text{cm}^2}{\text{gm.}}\right) =$$

$$2\ 5 \times 10^{-8}\ \text{cm /sec}^2 \qquad (11)$$

(ii) Gravity

$$a_G = 980\, r^{-2} \qquad (12)$$

(iii) Magnetic

With the circular velocity $w \sim 8 \times 10^5\, r^{-1/2}$ cm /sec, and with the magnetic field $B \sim 0\ 5\, r^{-3}$ gauss, we obtain.

$$\begin{aligned} a_M &= Ze\,w\,B/m \\ &= 10^{-5}\,(r-2)\, r^{-3.5}\ \text{cm./sec}^2 \qquad (13) \end{aligned}$$

Effects of Coulomb Drag

The changes in orbit and life-time of a satellite in the presence of a dissipative drag force F_D can be treated most simply by energy considerations[17]

The loss of energy per orbit in a circular orbit is $\Delta E = 2\pi r F_D$ and this will reflect itself in a lowering of the orbit by an amount Δr in a time T which is simply the orbital period

$$T = 2\pi\ (GM_E)^{-1/2}\, r^{3/2} \qquad (14)$$

Since the total (kinetic+potential) energy is given by $E = \frac{1}{2}\ GM_E m/r$, we obtain by differentiation

$$\Delta r = (-\Delta E)\ 2r^2/GMm \qquad (15)$$

We can therefore obtain an expression for the rate of shrinkage of a circular orbit as follows

$$\Delta r/\Delta t = 2\pi r F_D\ \frac{2r^2}{GMm}\,\frac{(GM)^{1/2}}{2\pi r^{3/2}} = \frac{2}{(GM)^{1/2}}\,\frac{F_D}{m}\ r^{3/2} = \frac{1}{\pi}\ T\ \frac{F_D}{m} \qquad (16)$$

which is $(1/\pi)$ times (the orbital period) times (drag deceleration)

We can also express $(\Delta r/\Delta t)$ as a function of r using equation (10) for Coulomb drag and using $T = 5{,}080\ r^{3/2}$ for orbital period

$$(\Delta r/\Delta t)_C = \sim 5 \times 10^{-2}\ (r-2)^2\, r^{-3/2}\ [\text{cm /sec }] \qquad (17)$$

This expression may now be compared with the neutral drag acceleration evaluated from

$$F_N/m = \tfrac{1}{2}\ C_D A \rho\ w^2/m = \tfrac{1}{2}\ C_D\ A(n_H m_H + n_0 m_0)\ w^2/m \qquad (18)$$

where C_D is the drag coefficient, A the projected area and ρ the density measured in gm /cm $^{-3}$.

Using $w^2 = (7\ 9 \times 10^5)^2/r$, $m = 10^{-4}$ gm , $A = 5 \times 10^{-3}$ cm ^{2}, $C_D \sim 2$; we obtain.

$$\begin{aligned} F_N/m &= 5 \times 10^{-3} \times 1\ 66 \times 10^{-24}\ (n_H + 16\ n_0)\ (6\ 25 \times 10^{11})\ 10^4/r \\ &= 5\ 2 \times 10^{-11}\ (n_H + 16\ n_0)/r\ [\text{cm /sec }^2] \qquad (18') \end{aligned}$$

In the case of a particle belt, it is more relevant to calculate $(\Delta r/\Delta t)$ rather than the change in orbital period

$$\begin{aligned} (\Delta r/\Delta t)_N &= 1/\pi\,(5{,}080\, r^{3/2})\, 5{\cdot}2 \times 10^{-11}\,(n_H + 16 n_0)/r \\ &= 8\ 4 \times 10^{-8}\,(n_H + 16\, n_0)\, r^{1/2}\, [\text{cm /sec }] \qquad (19) \end{aligned}$$

It is of considerable interest to establish the relative importance of the two drag forces In order to do this we must adopt a model for the structure of the magnetosphere

Observational information is limited to rather low altitudes The distribution of mass density below 800 km is known from analysis of satellite drag[18] The integrated thickness of the neutral hydrogen cloud around Earth is known from analysis of the profile of solar hydrogen Lyman-α (ref 19) Electron densities up to 1,500 km are known from rocket measurements[20] The electron density to several Earth radii is inferred (with some uncertainty) from whistler observations[21,22]

On the other hand, the *relative* distributions of the neutral constituents can be deduced from a theory of the exosphere[23] The neutral components describe ballistic orbits without collisions above the base of the exosphere (530 km) and the distribution of concentration with altitude is calculable in a fairly straightforward manner The ionized components (having much larger cross-section because of Coulomb interaction) are distributed according to the barometric formula[24] In each case the slope (or scale height) is determined by the temperature at the base of the exosphere Using the data referred to above for normalization, it is possible to construct a model of the exosphere[25] This model is shown in Table 1

Table 1 CONCENTRATION OF MAJOR CONSTITUENTS IN THE TERRESTRIAL EXOSPHERE (CM $^{-3}$)

r/R	O	O+	H	H+
1 100	$1\ 2 \times 10^7$	5×10^5	10×10^3	—
1 200	$2\ 7 \times 10^4$	$2\ 5 \times 10^4$	$6\ 6 \times 10^3$	9×10^3
1 300	$1\ 7 \times 10^2$	$1\ 7 \times 10^3$	$4\ 4 \times 10^3$	$6\ 6 \times 10^3$
1 400	1	$1\ 3 \times 10^2$	$3\ 1 \times 10^3$	5×10^3
1 500	—	11	$2\ 3 \times 10^3$	$3\ 7 \times 10^3$
1 75		< 0 1	$1\ 25 \times 10^3$	$2\ 1 \times 10^3$
2 00			8×10^2	$1\ 3 \times 10^3$
3 00			2×10^2	$3\ 5 \times 10^2$
4 00			82	$1\ 5 \times 10^2$
5 00			43	85
6 00			25	51
7 00			16	33
8 00			12	23
9 00			9 1	17
10			6 5	11

Both neutral and Coulomb drag decelerations are shown in Table 2, as well as the resulting values of $(\Delta r/\Delta t)$ It must be pointed out, however, that the Coulomb drag depends on many detailed factors (some of which were discussed earlier), involving the particular properties of the particle, of the exosphere, and of the Sun, as well as the particulars of the orbit

The zero value of Coulomb drag at $2R_E$ should not be taken literally, it merely indicates that somewhere in this altitude-range there may be a minimum As discussed elsewhere, small fluctuations of charge will produce a drag (since it depends on the square of Z and not on the sign), in particular, the day–night effect sets a lower limit to the Coulomb drag[5] This minimum may give rise to a high concentration of interplanetary smoke (particles $\gtrsim 1\mu$) near 2 Earth radii if they exist

Discussion

It would be of interest to calculate the life-times of the West Ford particles Since the details of the orbit have not been revealed, and, in particular. since the altitude and orbit inclination are not known, it does not seem worth while to attempt any refined calculations There are in any event uncertainties about the electric charge of the particle, about its attitude with respect to magnetic field and with respect to the Sun, and also about the actual values of air density

With initial orbit details available, the subsequent history of the West Ford particles can only be obtained by numerical methods It is clear, by referring to Table 2, where the neutral drag may be neglected It is clear also, by referring to equations (10), (11), and (13), that probably none of the other forces can be neglected, except for very special orbits (It is interesting to note the importance of the radiation pressure in relation to the Coulomb drag This is due to the geometric shape of the needles It should be noted that for a spherical interplanetary dust particle of the same mass, the radiation pressure acceleration is $\sim 5 \times 10^{-5}\ \pi a^2/m$ and is, relatively,

Table 2 DRAG DECELERATION AND ORBIT SHRINKAGE

r/R	a_N (cm /sec ^{2})	$(\Delta r/\Delta t)_N$ (cm /sec)	a_c (cm /sec ^{2})	$(\Delta r/\Delta t)_C$ (cm /sec)
1 1	9×10^{-3}	$1\ 7 \times 10$	$1\ 8 \times 10^{-5}$	$3\ 5 \times 10^{-2}$
1 2	$3\ 6 \times 10^{-5}$	$7\ 6 \times 10^{-2}$	$1\ 1 \times 10^{-5}$	$2\ 4 \times 10^{-2}$
1 3	$1\ 5 \times 10^{-6}$	$3\ 6 \times 10^{-3}$	$6\ 9 \times 10^{-6}$	$1\ 7 \times 10^{-2}$
1 4	$3\ 7 \times 10^{-7}$	1×10^{-3}	$4\ 0 \times 10^{-6}$	$1\ 1 \times 10^{-2}$
1 5	$2\ 1 \times 10^{-7}$	$6\ 1 \times 10^{-4}$	$2\ 2 \times 10^{-6}$	$6\ 8 \times 10^{-3}$
1 75	$9\ 8 \times 10^{-8}$	$3\ 7 \times 10^{-4}$	$3\ 6 \times 10^{-7}$	$1\ 4 \times 10^{-3}$
2 0	$5\ 5 \times 10^{-8}$	$2\ 5 \times 10^{-4}$	(0)	(0)
3 0	$9\ 5 \times 10^{-9}$	$7\ 9 \times 10^{-5}$	$1\ 1 \times 10^{-6}$	$9\ 6 \times 10^{-3}$
4 0	3×10^{-9}	$3\ 9 \times 10^{-5}$	$1\ 9 \times 10^{-6}$	$2\ 5 \times 10^{-2}$
5 0	$1\ 4 \times 10^{-9}$	$2\ 4 \times 10^{-5}$	$2\ 1 \times 10^{-6}$	$4\ 0 \times 10^{-2}$

100–1,000 times smaller when compared with the Coulomb drag[5,7].)

In a numerical computation, particular attention must be paid to the day–night effect, not only on radiation pressure, but also on the particle charge. In fact, because of fluctuations in radiation belt intensity, solar flares, and similar factors, the charge will fluctuate unpredictably. This effect will contribute to a spreading of the belt which is, in addition to the dispersion, calculated by the Lincoln Laboratory[4].

Nevertheless, the shrinkage of an initially circular orbit produced by loss of energy due to drag is a gross effect which should be observable, and which gives some information on air density as well as about the importance of Coulomb drag.

A Proposed Experiment

However, a much more refined experiment is possible which illuminates the interaction of small particles with the magnetosphere. It is based on a separation of the perturbing forces.

Consider, for example, an initially circular orbit at ~ 3,200 km altitude ($r = 1.5\ R_E$), nearly polar and perpendicular to the Earth–Sun line. In this special orbit the radiation pressure does not produce any appreciable perturbation (at least initially), and the Lorentz force perturbation can be determined quite simply, although it is again negligibly small. Since the velocity vector of the particle is more or less in the plane of the magnetic meridian, the chief perturbation will be orthogonal and cause a rotation of the orbital plane. The sense of the rotation establishes the sign of the electric charge on the particle. Using the analysis leading up to equation (13) I estimate the rate of rotation of the orbital plane as about 10^{-11} rad./sec., and rather unobservable.

Next consider a modification of the photoelectric properties of the copper needles. Specifically, one-third could be left with their present copper surface, one-third would be coated with a material of high work function W and low photoelectric yield γ (for example, platinum), and the remainder with a material of opposite characteristics (possibly a cæsium alloy). For our particular orbit, the copper particles would be negative, the platinum particles even more negative, while the cæsium particles would have a nearly zero potential, or perhaps be even positive.

Because of Coulomb drag the three belts will shrink at different rates. Using the analysis leading up to equation (17) I estimate a differential rate of shrinkage of orbit radius amounting to nearly 5 m. a day.

Thus the separation of this West Ford belt into three layers might be resolvable with available radar methods, provided the dispersion of the particles at injection can be held very small.

I am indebted to A. E. Lilley, W. E. Morrow, E. J. Öpik, I. I. Shapiro, and E. H. Walker for helpful discussions. The investigation was supported by the Air Force Office of Aero Space Research under grant *AFOSR*-61-57.

NEWS and VIEWS

Royal Aircraft Establishment: Mr. R. J. Atkinson

MR. RONALD JOHN ATKINSON has been promoted to deputy chief scientific officer and has taken up the post of head of the Structures Department at the Royal Aircraft Establishment, Farnborough, in succession to Dr. Percy B. Walker, who has been appointed special consultant to the director of the Establishment. Mr. Atkinson, an Australian, came to Great Britain in 1936 with a Rhodes Scholarship from the University of Queensland. After studying at Oxford under Sir Richard Southwell, he went to the Imperial College of Science and Technology for a year, and later was with Fairey Aviation, Ltd., at Stockport. He joined the Royal Aircraft Establishment in May 1940, and was appointed head of the Fatigue Division of the Structures Department in 1955. He is a bachelor of engineering of the University of Queensland, holds the diploma of the Imperial College and is a Fellow of the Royal Aeronautical Society.

Research and Development in the Gas Industry

DR. J. A. GRAY, group leader of physical chemistry and chemical engineering at the Battelle Memorial Institute, Geneva, since 1958, has been appointed head of the new Basic Research Group which the Gas Council is establishing at its London Research Station at Fulham. Dr. Gray is a graduate of King's College, University of London, and prior to joining the staff of the Battelle Memorial Institute, was employed in the Alkali Division of Imperial Chemical Industries, Ltd. In forming the Basic Research Group, the Gas Council's intention is to provide the industry with the means of developing entirely new ideas for the production and utilization of gas without being bound by short-term considerations, or the need to produce results to a definite programme. Although, for administration purposes, it will form part of the Council's London Research Station, the Basic Research Group will operate independently, and the head of the Group will be a member of the

Council's Research Committee, and will exercise full control over the Group's scientific work.

Air Force Cambridge Research Laboratories

MAJOR changes were recently announced for the Air Force Cambridge Research Laboratories, Bedford, Massachusetts, by the commander, Brigadier-General B G Holzman The changes were aimed at strengthening the research programme and the management structure of the Laboratories, and preventing the tendency for overlap of work within the Directorates The separate staffs of the two Directorates of the Air Force Cambridge Research Laboratories, the Electronics Research Directorate and the Geophysics Research Directorate, plus a small headquarters staff, were combined to form a single headquarters staff that now serves both Directorates However, the various laboratories coming within these Directorates are not affected by the reorganization Heads of the four major staff elements are· Dr A M Gerlach, deputy for plans and programmes; Lt -Colonel Eugen Duff, deputy for administrative management, Mr V S. Dempsey, deputy for logistics; and Mr L E Woods, research information officer In addition, a new division was created to provide technical services to the Laboratories' scientists under the direction of Mr V. S Dempsey Dr L M Hollingsworth continues as director of electronics research Colonel Ernest A Pinson continues in the dual capacity of the Laboratories' deputy commander and director of geophysics research, positions he has held for the past year However, Colonel Edward M Douthett, at present assigned to Headquarters, U S Armed Forces, will assume duty as director of geophysics research in mid-November.

Revision of School Science Curricula

IN reply to a question from Viscount Samuel in the House of Lords on October 18 as to what action was being taken to implement the recommendation of the Advisory Council on Scientific Policy regarding the revision of school science curricula, the Minister for Science, Lord Hailsham, said that this has been carefully considered by himself and the Minister of Education In England and Wales the initiative for framing curricula and syllabuses rests with the teaching profession and, after a very thorough review, the Association of Women Science Teachers and the Science Masters' Association have recently proposed substantial revisions and modernization of existing syllabuses The Minister of Education is encouraging these and similar efforts to revise the syllabuses, and the proposals of the Science Masters' Association are being used by the General Certificate of Education examining bodies as the basis for the revision of their examination syllabuses which they are undertaking at the request of the Secondary School Examinations Council This Council advises the Minister on the general direction of the General Certificate of Education examination, and schools, universities, local education authorities and other bodies concerned are represented on it Corresponding action has been taken independently in Scotland through the Scottish Education Department

The CERN Laboratory, Geneva

IT was at the end of 1959 that the 25-GeV proton synchrotron came into operation in the CERN laboratory at Geneva (European Organization for Nuclear Research, CERN Annual Report, 1960 Pp 113 Geneva CERN, 1961) During 1960 the beam intensity was increased ten-fold to 10^{11} protons/sec and the experimental hall was equipped for beam transport In the past quarter 504 operating hours were devoted to nuclear physics experiments These experiments opened up a new energy region in the study of the elementary particles. On the synchro-cyclotron the experimental groups have continued to make distinguished contributions to meson physics Probably the most impressive of these was the measurement of g-2 for the muon to an accuracy of 2 per cent The completion of the new muon channel must mean major progress in muon physics within the next few years To cope with the increasing amount of experimental data, particularly from bubble chambers, an IBM 709 computer was installed during the year

The original programme defined in the convention of 1953 is now virtually complete This is a brilliant achievement but, as the report makes clear, CERN has no intention of resting on its laurels Work is in progress to improve the facilities on both the accelerators and a major contribution to nuclear physics is guaranteed for many years to come Even so, the director-general, in his introduction, refers to longer-term plans for a new accelerator in 1970 All this is an indication that the CERN laboratory is a lively and interesting place, an outstanding example of international collaboration Confirmation of this can be found by reading the report, which gives a vivid and particularly well-illustrated account of the laboratory's achievements and activities in 1960.

Political and Economic Planning

THE annual report of Political and Economic Planning for the year ended March 31, 1961, includes a list of publications, 1960–61, and of PEP staff for the year, but deals essentially with the research programme Continued progress is reported with the study of Britain and the European Common Market and the preparation of a report on Atlantic Tariff and Trade has proved to be a major undertaking This study is assisted with a generous three-year grant from the Ford Foundation. Two new major projects launched during the year were concerned with trade unions in a changing society and with present-day trends in the development of community mental health services, the former being supported by a substantial grant from the Leverhulme Trust Fund, and the latter by a grant from the Nuffield Provincial Hospitals Trust An inquiry is also being launched into the effects on wives and dependants when the chief male earner is imprisoned An examination of the work of professional and learned societies, with special reference to any difficulties imposed by modern industrial conditions, is also being carried out, and provisional help has been promised by the Department of Scientific and Industrial Research

Scientific Research in Australia

THE Research Review of the Commonwealth of Australia Scientific and Industrial Research Organization for the year ending June 30, 1960, is the complement of the shortened form in which the Organization's twelfth annual report was presented, with which it is intended to be read (Pp iv+418 Melbourne Commonwealth Scientific and Industrial Research Organization, 1961) It presents the scientific details of the research programme in much the same way as the earlier annual reports, each of its 48 chapters being devoted broadly to one division or section of the Organization. Lists of professional staff, published scientific papers and financial details are excluded and are given in the annual report.

Research Grants in Science and Medicine in Canada

The report on *University Support*, 1960–61 (Pp. 123. N.R.C. No. 6390. Ottawa: National Research Council and Medical Research Council, 1961. 50 cents), issued by the National Research Council and the Medical Research Council of Canada, records support totalling 8,169,564 dollars from the National Research Council and 2,304,467 dollars from the Medical Research Council. Of the former figure, 7,169,402 dollars represent direct support by way of scholarships in science and engineering (738,467), fellowships in science and engineering (396,758) and grants in aid of research through the Assisted Researches Committee (4,267,195), Prairie Regional Committee (232,458), Atomic Energy Control Board (650,000) or General Research grants (492,000), and 1,000,162 dollars indirect support, including 285,589 dollars for publication costs of research journals and 227,334 dollars for the administration of the programme. The latter includes 189,326 dollars for fellowships, 204,191 dollars for associateships and 1,899,809 dollars for grants in aid of research. The totals represent increases of 1.11 million dollars over 1959–60 and 7 million dollars over 1956–57. Besides listing the membership of the Councils and their officers and committees, the report lists the recipients of fellowships, bursaries and scholarships for the period 1960–61 and the subjects of research grants.

The Wildfowl Trust

The Wildfowl Trust has again prepared an annual report which is a model of presentation (*The Twelfth Annual Report of the Wildfowl Trust, 1959–1960*. By Hugh Boyd and Peter Scott. Pp. 185+24 plates. Slimbridge: The Wildfowl Trust, 1961. 17*s*. 6*d*. net). Practical administrative matters are described clearly and briefly, scientific topics are many and varied, and there are the usual high-quality photographs and line drawings which make the reading of the report an event to be anticipated rather than a duty to be overcome. Unfortunately, the twelfth year of the life of the Trust has seen a drop in the number of visitors to Slimbridge and Peakirk, and it is to be hoped that the decline is only temporary. Probably the most interesting and disturbing scientific article is one by J. M. and J. G. Harrison, who have collected evidence to show that radioactive contamination in birds is beginning to increase. While risks to wildfowl are but a tiny facet of the bigger problem of radioactive contamination, wildfowl may be particularly susceptible, especially those breeding in the far North, where the hazards from radioactive fall-out may be at their greatest. The added risks from the disposal of radioactive industrial waste products may again render wildfowl and seabirds more susceptible than other groups of birds.

London and Guildhall Museums

The Government and the Corporation of London and the London County Council have agreed in principle to establish one Museum dealing with the history of London. This will involve the amalgamation of the present London and Guildhall Museums and the full approval of each of the governing bodies is assured. The new Museum will be situated in the City of London, probably on a site close to the Roman Wall. Although details have not yet been agreed, it is probable that the governing body will consist of representatives appointed by the Prime Minister, the City Corporation and the London County Council. When the details have been agreed by the authorities, an Act of Parliament will be necessary to implement the scheme.

Rocket Propulsion Thirty Years Ago

The science and technology of rockets have advanced from being the hobby of a few apparent cranks to become major consumers of taxpayers' money, even in the universities the type of student who immediately after the War would have sought to accomplish research on the gas turbine, and later would have followed changing fashion and interested himself in nucleonics, now regards rockets as pointing the way to the stars. In spite of the great achievements of the age, however, it is interesting to look back at the pioneer work of another student at the Imperial College of Science and Technology, London. A paper, originally read by Mr. Paul Adorian in 1929, has been reprinted and the proceeds from the sale of these reprints is to be given to the Henry Tizard Memorial Fund. The paper contains little original matter, but it does give a picture of the approach to rocket propulsion more than thirty years ago, and a contemporary point of view of such developments as the Opel rocket cars, designs for jet aircraft curiously modern in style, and a German rocket gun which its open-minded inventor claimed could "shoot London from Berlin, or if you prefer it, shoot Berlin from London". Copies of the reprints are available from Mr. P. Adorian, 21 Denmark Street, London, W.C.2 (price 8*s*. or 1.25 dollars).

The Cambridge Rheology Club

A recent meeting of the Cambridge Rheology Club was held on September 11 in the form of an exhibition of rheological equipment. Mr. C. H. Rose (Cambridge Instrument Co.) demonstrated the dye dilution curve recorder and described its uses in the investigation of certain defects of the vascular system. Grant Instruments showed notably a low-temperature thermostatically controlled bath (Model *RB6P*). Miss M. Nicholas (Spillers, Ltd.) demonstrated the cattle cube hardness tester, which may also be used for strength tests on paper and similar materials. She dealt briefly with the statistical evaluation of the results. Dr. N. A. de Bruyne (Techne, Ltd.) discussed an extensive range of rheological instruments, including the gelation timer, capillary viscometer, various temperature control units and the automatic printing viscometer, still in the experimental stage. The next meeting of the Club will be held on November 27, at 7.45 p.m., when Dr. R. McKennell (Ferranti, Ltd.) will speak on "Rotation Viscometers and their Application to Non-Newtonian Measurements", followed by a demonstration of the Ferranti–Shirley viscometer. Further information can be obtained from Mr. H. G. Muller, Spillers, Ltd., Technological Research Station, Station Road, Cambridge.

Tables and Charts for Use in Gas Dynamic Studies

The Sandia Corporation has recently issued a very useful bibliography (*SCR*–299), by D. E. Randall, listing references which provide tabulated or graphical data regarding the atmosphere, gas flows, flow through shock waves, and information on the thermodynamic and transport properties of gases. Included in the list is a new Sandia monograph (*SCR*–288), by K. L.

Goin, entitled "Mach Tables for Real Gas Equilibrium Flow of Air in Hypervelocity Test Facilities with Total Temperatures to 10,000° K." This report tabulates the aerodynamic flow parameters for isentropic expansions and flow through normal shocks in the pressure range 100–4,000 atmospheres. Both the bibliography and the monograph are available, price 0 75 and 2 0 dollars, respectively, from the Office of Technical Services, Department of Commerce, Washington 25, D C

Gairdner Foundation Awards

GAIRDNER FOUNDATION awards have been made to the following in recognition of their contributions to the study of arthritis and heart diseases Dr Alan C Burton, professor of biophysics, University of Western Ontario, for his work on blood circulation, Sir Russell Brock, cardiac surgeon at Guy's Hospital and Brompton Hospital, London, for his work on heart surgery, Dr Jonas H Kellgren, professor of rheumatology and director of the Rheumatism Research Centre, University of Manchester, for his work on the incidence of rheumatoid arthritis, Dr Alexander B Gutman, director of the Department of Medicine, Mount Sinai Hospital, New York City, for his work on the treatment of gout, Dr. U S von Euler, professor of physiology, Karolinska Institutet, Stockholm, for his work on noradrenaline and its effects on body functions

The Royal Institution of Naval Architects: Awards

THE Council of the Royal Institution of Naval Architects has announced the following awards *Denny Scholarship in Marine Engineering* (1961), to Mr David K Brown (17), of Kelvinside Academy, Glasgow (£350 per annum for four years at the University of Glasgow), *Parsons Scholarship in Marine Engineering* (1961), to Mr Alan B Turner (21), of Messrs Alfred Holt and Co , Ltd , Liverpool (£400 per annum for three years at the University of Durham, King's College, Newcastle upon Tyne)

The Meldola Medal for 1961

THE Meldola Medal is the gift of the Society of Maccabæans and is normally awarded annually The next award will be made early in 1962 to the chemist who, being a British subject and under thirty years of age at December 31, 1961, shows the most promise as indicated by his or her published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31, 1961 No restrictions are placed upon the kind of chemical work or the place in which it is conducted The merits of the work may be brought to the notice of the Council, either by persons who desire to recommend the candidate or by the candidate himself, by letter addressed to the President, Royal Institute of Chemistry, 30 Russell Square, London, W C 1

The Association of Clinical Biochemists

THE following officers were elected at the annual general meeting of the Association of Clinical Biochemists *President*, Dr A L Latner, *Chairman*, Mr H Varley, *Honorary Treasurer*, Dr R Gaddie; *Honorary Secretary*, Dr J H Wilkinson, Westminster Medical School, Horseferry Road, London, S.W 1

Announcements

DR RALPH P HUDSON has been appointed chief of the Heat Division at the National Bureau of Standards, U S Department of Commerce He succeeds Dr Charles M Herzfeld, who was recently appointed associate director of the Bureau

THERE will be open days at the Humber Laboratory at Hull of the Department of Scientific and Industrial Research on November 9 and 10 Exhibits will include some of the work of the parent laboratory, the Torry Research Station at Aberdeen Both laboratories deal with the handling, processing and distribution of fish.

THE Welsh Soils Discussion Group will meet at the Department of Biochemistry and Soil Science, School of Agriculture, Bangor, on November 15. The subject for discussion is "Aspects of the Dynamic Organic Matter Cycle in Soils". Further information is available from Mr J A Taylor, University College, Alexandra Road, Aberystwyth

THE four hundred and tenth meeting of the Biochemical Society, for the presentation of original communications, will be held in the Department of Biochemistry, Manchester College of Science and Technology, on November 11 Further information can be obtained from Dr W J. Whelan, Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S W 1.

THE office of the Biochemical Society and the editorial office of *The Biochemical Journal* have now moved to 20 Park Crescent, Regent's Park, London, W 1 All communications connected with *The Biochemical Journal* should be sent to that address

A SPECIALISTS' conference on culture collections will be held in Ottawa, Canada, during August 27–28, 1962 Topics for discussion will include fundamental and technical aspects of the preservation of culture of micro-organisms and other cells Special emphasis will be placed on the maintenance of morphological, physiological and genetical characteristics Attendance at the conference will be by invitation only. Persons interested in attending are invited to write to Dr S M Martin, Division of Applied Biology, National Research Council, Ottawa, Canada, before December 1, 1961

THE first Feldberg Foundation Lecture 1961 will be given by Prof. Herbert Hensel, director of the Physiological Institute of the University of Marburg, who will speak on "The Electro-physiology of Thermoreceptors" on November 2 in the Physiology Theatre, University College, London, Gower Street, W C 1 The Foundation was recently instituted (see *Nature*, 191, 1143, 1961) to encourage German–English scientific exchange for experimental medical research Further information can be obtained from Dr M Godfrey, Medical Research Council, 20 Park Crescent, Regent's Park, London, W 1

THE Czechoslovak Society of Arts and Sciences in America will hold its first national scientific congress in the Hotel Statler, Washington, D C , during April 20–22, 1962 There will be a two-day symposium on the contributions of the Czechoslovak science and arts to world culture The programme will include papers on science, medicine and technology, fine arts, literature and literary criticism, slavistics and linguistics, law and economics, history and political science, philosophy and sociology, and finally a special section will be devoted to Czechs and Slovaks abroad Further information can be obtained from Dr M Rechcigl, jun , secretary, Programme Committee, 1703 Mark Lane, Rockville, Md

DEVELOPMENTS IN ASTRONAUTICS

THOUGHTS on the seminar on "Astronautics", held in the University of Southampton during July 12–19, should be considered against the technology of the changing scene in air and space, an unsteady scene, its movements affected by engineering and scientific inventions The trend is to curtail weapon programmes, and in place of production quantities there is more limited manufacture of precision 'hardware', aircraft types are fewer and more highly specialized, benefiting from the development of rocket systems and instrumentation

The five groups of twenty-three interrelated lectures provided a clear picture of the scientific and technological aspects of the subjects, the result of painstaking planning by those to whom science was an intellectual adventure.

The seminar was organized by the N A T O Advisory Group for Aeronautical Research and Development and the University of Southampton Prof E J Richards, head of the first Department of Aeronautics and Astronautics in Great Britain (University of Southampton), introduced Mr E T Jones, deputy director of A G A R D , who welcomed the delegates, mentioning the fitness of the venue, the first of its kind, due to the enterprise of the professorial staff, particularly Dr B L Clarkson

Mr M. J Lighthill, director of the Royal Aircraft Establishment, gave the introductory lecture to about a hundred delegates from Europe and the United States Brilliantly he set the scene, introducing the subjects to be discussed, dealing with aims and organization of pure, and applied, space science and technology Space included the stars, planets, and everything known and predicted by the astronomers, to whom we are indebted for information, and with whom it is most desirable to co-operate

In pure science we are concerned with perturbations of orbits, macrometeorites in orbit, the fluctuating environment of plasma, solar activity, solar streams, and radiation effects, Van Allen belts, and plasma propulsion

In applied science we consider geodesy, navigation, transit satellites, observations, communications, geometric aspects of space, meteorology, information for synoptic meteorologists, the particular need for viewing clouds from above—thermal stability in satellites, solar cells, gyroscopes, and generally the application of discoveries useful for mankind For the future, *Blue Streak* and *Black Knight* would help in the further observation of the ionosphere and re-entry research as well as contributing to the communication satellites plan, now being handled by the Royal Aircraft Establishment and the General Post Office, the Commonwealth and the European Space Launcher Organization, this scheme is promising and will engender greater integration, economical development, technical adventure and co-operation over a wide field, and would attract the best men The co-operative scheme needs intensive planning for arranging the work, and a body to co-ordinate effort from design to the operating conditions This includes using existing institutions, avoiding extravagances, and avoiding the separation of aerodynamics, astronautics and space technology

Useful visits were made to the Royal Aircraft Establishment, the Radio Research Establishment, and the Royal Greenwich Observatory

"Orbits in the Solar System" was the subject of a lecture by Dr J G Porter, Royal Greenwich Observatory, and he was followed by Mr. D G King-Hele, Guided Weapons Department, Royal Aircraft Establishment, with a paper on "Earth-Satellite Orbits"

These papers dealt with orbits affected by perturbations As an astronomer, Dr. Porter was concerned with all the members of the solar group and their movements in continuously variable ellipses, and the method of defining the instantaneous orbit in which a body is travelling at a given epoch The figures in the published ephemerides of the Sun and planets are based on rectangular co-ordinates measured in astronomical units to seven decimal places, they are published so that observers may make a comparison with theory Tables of planetary co-ordinates for the next twenty years are available, and for Mars for every four days up to 2,000

Complementary to Dr J G Porter's talk, Mr D G King-Hele dealt in more detail with four main perturbations affecting the orbit of a satellite, caused by (1) the departure of the Earth's gravitational field from spherical symmetry, (2) the influence of atmospheric drag, (3) the luni-solar gravitational attractions, and (4) solar radiation pressure Near satellites, having a perigee height of less than 1,000 km , and apogee heights of less than 5,000 km , are affected particularly by 1 and 2 The third perturbation results from the asymmetry between the northern and southern hemispheres If the apogee height of a satellite is greater than 20,000 km (*Explorers* 5 and 10) the gravitational attractions of the Sun and Moon are important in addition to those already mentioned, and if the perigee height exceeds 1,000 km the force due to solar radiation pressure is greater than atmospheric drag

Prof T R F Nonweiler, Mechan professor of aeronautics and fluid mechanics, University of Glasgow, spoke on "Re-entry Orbits", discussing the two conditions in which re-entry will occur, either as the final result of the gradual contraction of the orbit by air resistance, or by deliberate perturbations (through the action of retro-rockets) The speed at the first stage of re-entry, say Mach 30, is changing to stage two at Mach 3 or 4, then to stage three at Mach 0 3–0 2, and finally the vertical drop While drag can be reduced, it is not possible to reduce the rate of heating, and this problem at hypersonic speeds has two satisfactory solutions, namely, ablation, and variable drag by flared skirt or parachute When retro-rockets are used to control the vehicle, the point of firing is important so that the vehicle hits the target Whatever the shape of the vehicle the maximum deceleration is the same, but it occurs at a greater height if the design is blunt and is of high drag, thus in the lower part of the atmosphere a blunt satellite has a lower speed and endures less heating A more streamline and faster-falling vehicle suffers intense heating in the denser part of the atmosphere where maximum deceleration occurs If the vehicle can be given some aerodynamic lift to modify the re-entry path, then the rate of heating and deceleration can be reduced

Captain P V H Weems, U S Naval Academy, rounded off the session on orbits by explaining his method of "Space Navigation" The basic concept is that the space observer's optical line of sight to the Earth's centre is in the observer's vertical Range is restricted to cislunar navigation and the space-vehicle is assumed to have sufficient power to enable it to be directed and navigated The Earth is used: (1) for fixing the position of the space observer's geographical position by observing visually the position of the Earth's centre relative to the stars, (2) for finding the distance from the Earth's surface stadimetrically by using the Earth's diameter as a base, (3) for guiding a space-vehicle by so changing its velocity as to cause the apparent path of the Earth's centre to follow a precomputed path The space navigator can fix the relative position of the satellite by using a two-way telescope, which would provide, simultaneously, fixes on the Earth's centre and the zenithal stars, and then tables will give the position The proposed *Space Almanac* has been started, by attempting to provide a space navigator for the *Echo* satellite with usable data, and it is intended for teachers and students one or two generations ahead of the astronaut

Prof E Vassy, of the University of Paris, in discussing "Physical Properties of the Upper Atmosphere", paid due tribute to the astronomers, and outlined the results from the *Veronique* research rocket, the programme being similar to that of the *Skylark*, there being close collaboration with the Royal Aircraft Establishment in the development of the mass spectrograph for ion measurement

Prof B Fraeijs de Veubeke, University of Liège, discussed the "Optimization of Space Vehicles and Launchers relative to their Missions", and showed that minimization of fuel consumption, initial weight, initial thrust for a given payload and given performance requirements lead to widely different missile configurations, and then there is the extensive analysis necessary to determine the minimization of cost of mission per unit payload

Prof L Broglio, Department of Aeronautics, University of Rome, explained "A Method for Solving Non-linear Thermal Problems in the Re-entry of Space Vehicles".

In "Some Recent Advances in the Theory of Control", Dr J K Lubbock, University of Cambridge, assessed the progress of control theory embracing non-linear systems, and dealt with the difficulties of analysis and optimization of feedback systems containing non-linear elements He reviewed the Fokker–Planck equation for the Markov processes, he believes that Pontryagins' general theory is the most significant theoretical advance in recent years

Dr W W Lines, Guided Weapons Department, Royal Aircraft Establishment, outlined the "Problems of Guidance in Astronautics" and dealt with methods for the injection of Earth satellites into orbit, and the problem of orbital transfer

Flight-Lieutenant J C Guignard, Institute of Aviation Medicine, discussed "Physiological Limitations of Man in Space" He said that from the physiological aspect, space begins at sea-level, and the basic problems extend to meet the conditions discussed in the seminar are being studied in simulation laboratories The absence of normal diurnal and seasonal cycles during flights of weeks or months demands new knowledge

Dr E V. D Glazier, Royal Radar Establishment, discussed the radio problems for interplanetary space probe missions where the range may be many millions of miles, but at present there are limitations on probe transmitter power and life, and on the extent of costly ground facilities Measurement of range is achieved by the secondary radar principle, and good tracking in range and angle can be obtained out to ten million miles with a slight extension of present techniques For reciprocal and rapid transmission during a Venus mission, more powerful transmitters and aerials of the Jodrell Bank type are essential

In a paper on "Hypersonic Aerodynamics", Mr K M C Bray, University of Southampton, said that perfect fluid hypersonic effects, real gas effects and high-altitude effects are three classes of problem that may occur simultaneously, but they must be studied separately in order to provide information for the design of the blunt-nosed ballistic vehicle or the slimmer boost glider type The designer needs to know the heat-transfer rate at the stagnation point, perhaps in the presence of ablation, then data about drag and dynamic stability Due to the Faraday effect, under hypersonic conditions radio signals to a vehicle suffer serious interference

Complementary to Mr K M C Bray's paper was "Laboratory Facilities and Techniques for Rarefied Gasdynamics Research", by Mr R L Chuan, director, Engineering Centre, University of Southern California, who stressed the need for more advanced designs of experimental apparatus to analyse the problems raised by Mr Bray Four types of facilities of various degrees of complexity and cost are needed the wind tunnel, shock tubes, molecular beam, and the rotating arm The study of hypersonic phenomena requires conditions in air of Mach number greater than 10, a Reynolds number less than 100, and a static temperature of about 300° K Pressure, temperature, density, speed, gas composition are basic quantities to be measured, the pressure being of the order of 10^{-6} atm , and this Mr Chuan had achieved by designing a low-density hypersonic tunnel around a cryopump cooled by a helium refrigerator achieving 20° K.

Mr D J Johns, College of Aeronautics, reviewed the design of the thin cylindrical structures typical of the liquid-fuelled launching vehicles, covering all the ground handling and flight conditions until impact on landing They included pressurization, axial and lateral loads, thermal, dynamic and space environment effects In general, the pressure-stabilized structure is lighter and simpler than the conventionally stiffened type The inflatable structure has minimum structural density, maximum volume/weight ratio, and unmatched packageability for the launch phase Prof A J Murphy, principal of the College of Aeronautics, spoke about the nature of the environment in outer space, and its significance for "Materials for Astronautic Vehicles", and said that the requirements discussed by Mr D. J Johns could be met by the use of metals of higher melting point, especially beryllium, molybdenum, columbium and tungsten, and also non-metals such as carbon, ceramics, or metal–ceramic mixtures Refractory metals withstand 1,370° C at stressed conditions but need protection against oxidation Heat-dissipating ablation surfaces of organic material are satisfactory.

Prof E J Richards (Southampton) discussed "Some Problems of Noises in Ballistic Missiles", briefly sketching the effect of noise-levels on structures and instruments between 100 and 180 decibels, at 140–150 db structures begin to crack, and at 170 db cracking is immediate To guard against trouble, there must be a detailed analysis of the environment of noise around a vehicle both during launching and at re-entry The source of most efflux noise of a rocket is about eighteen diameters downstream, the unsteady conditions with fluctuating pressures arising from turbulent mixing of the gas in the jet, from the rough flow in the boundary layer, and from the movement of the missile in turbulent air, fluctuating shock waves buffet the missile Noise may be real and radiated acoustically or as hydrodynamic pressure fluctuations exciting the structure and causing acoustical radiation inside it

Mr G K C Pardoe, chief weapons research engineer, De Havilland Co., spoke on "Space Flight Projects based on *Blue Streak*" His practical outlook brought together the theoretical and design philosophies discussed in other papers *Blue Streak* will have a fundamental part in the proposed research work on probes, satellite communication and meteorology, and this activity means that the European Space Launcher Organization should get off to a good start Mr Pardoe reviewed the *Eslo* three-stage launcher based on *Blue Streak*, with a second stage of French design Various third stages have been proposed and could produce high or low thrust, depending on the kind of mission, *Black Knight* with Bristol Siddeley *Gamma* engine would give a versatile performance. Mr C R Turner, of the De Havilland Co , spoke on "Communication Satellites", describing a world-wide coverage scheme based on *Blue Streak*

Prof P C Parkes, Control Engineering Department, University of Southampton, speaking in Russian, welcomed Prof A M Bobrov, chief scientist, Astronomical Society, Academy of Sciences, U S S R , who discussed the "Cosmological Neighbours of the Earth" from the astronomer's point of view, referring to the Sun, and the atmosphere of the Moon, Venus and Mars Astrobiological laboratories are growing plants under simulated Martian conditions A third belt of radiation has been located beyond the Van Allen belts

Dr R R. Jamison, assistant chief engineer (ramjets), Bristol Siddeley Engines, Ltd , in discussing "Advanced Air-breathing Engines", said that the use of these engines for astronautical work was as propulsion units for space-vehicles during the boost phase of space missions Studies based on development work show that the ramjet has a better fuel specific impulse than a typical rocket engine and so should be a better first-stage booster, faster and lighter It must operate up to speeds which are a significant proportion of orbital velocity, and research indicates that speeds much higher than the present operable Mach 6 can be achieved

Mr. S L Bragg, chief scientist, Rolls Royce, Ltd , discussed "Operation and Control of Liquid Propellant Rocket Engines", and explained the difficult handling problems of starting, keeping the engine running, and stopping. The *Blue Streak* engine is the *RZ*-2, using liquid oxygen and kerosene Accurate control of the moment at which the engine is shut down is essential to enable the accelerating vehicle to follow the flight plan After the stopping signal, there will be a brief time while the engine runs down, and on a multi-stage rocket it is desirable that the thrust should cease before the stages separate to avoid the possibility of subsequent collisions

Mr. P A E Stewart, rocket and satellite systems engineer, Hawker Siddeley Aviation, Ltd , in dealing with "Advanced Propulsion Systems for Space", reviewed the three main classes (*a*) high acceleration, covering free-radical rocket propulsion, open-cycle thermonuclear propulsion, and ionospheric recombination ramjets, (*b*) for medium acceleration there is solar energy, and (*c*) for low acceleration the closed-cycle nuclear system and variations of the electrodynamic types, electro-thermal or arc-jet, electrostatic or ion engine, the magnetohydrodynamic type, and the photon system

Group (*c*) attracted most interest, progressive laboratory work has been achieved in electrical propulsion and the arc-jet is well advanced Electric propulsion provides jet velocities 5–10 times those of nuclear engines, but as the thrusts are limited to pounds and fractions of a pound, they are promising only in space flight, but the problems are chemical and mechanical Then there is the question of space-flight test-beds. A CADMAN CLINTON

THE COLONIAL DEVELOPMENT CORPORATION

Annual Report, 1960

THE annual report and statement of accounts of the Colonial Development Corporation for the year ended December 31, 1960, the first to appear over Lord Howick's signature, who, as chairman, succeeded Sir Nutcombe Hume on December 1, 1960, follows the pattern of recent reports* Ninety-one continuing projects are reported as compared with 88 in the previous year, including 10 new projects totalling £11,675,000 Seven projects have been removed from the list and total commitments aggregated £109,448,000 compared with £96,145,000 in 1959 Of this aggregate, £14·6 million was in the Caribbean, £19 4 million (including £12 8 million for the Federation of Malaya) in the Far East, £22 7 million in East Africa, £22 0 million in Central Africa, £16 0 million in the High Commission Territories, and £14 7 million (including £205,000 in Ghana and £8 9 million in the Federation of Nigeria) Functionally 52 5 per cent of the committed capital was for basic development, 38 3 per cent for primary production and processing, and 9 2 per cent for commerce and industry

The report is at pains to emphasize the nature of the Corporation's task and some of its achievements in Africa It is believed that the Corporation can make an important contribution to the economic life of the emerging peoples for several reasons Its regional organizations have now been established for nearly ten years and its employees are able to relate business needs to the conditions of the region They have come to know well some leading people in the political and commercial life of their region, and are accustomed to working with them The Corporation is able either to take a shareholding or make a loan according to whether the principal need of a country is, at one time, for an equity type investment or, at another time, for a loan, and those in charge of the Corporation have become accustomed to working with many partners and have learned, for example, the importance of the pilot scheme stage in development projects

---

* Colonial Development Corporation Annual Report and Statement of Accounts for the year ended 31st December, 1960 Pp vi+82 (London H M S O , 1961) 5*s* net

The achievements of the Corporation in Africa are illustrated by reference to the Mhlume Sugar Mill in Swaziland, built in partnership with Sir J L Hulett and Sons, on a Corporation irrigation project, which will have produced by the end of 1961 more than 40,000 tons of sugar, the new pulp mill at Usutu Forests in the same territory, with an annual output of 100,000 tons , the Lobatsi abattoir in the Bechuanaland Protectorate, the launching of the Kilombero Sugar Co , Ltd , in Tanganyika, with the International Finance Corporation, Dutch interests and the Standard Bank of South Africa, and the agreements concluded in Nyasaland to provide up to £1,300,000 for the Mudi River Water Board to relieve the water shortage in Blantyre and Limbe The value of the Corporation's activities has equally been clear in countries which have become independent since the Corporation was established

As regards future possibilities, the report stresses particularly that, while remaining fully commercial, the Corporation could and should give the help which smallholders need in loans in processing and marketing their produce and in establishing a few larger farms for demonstration and for experiments with new agricultural methods, because development of smallholder farming can contribute powerfully to the stability of a country In small or sparsely inhabited territory the Corporation can often do much and is frequently irreplaceable, as is shown by the hydroelectric scheme in Dominica and in St Vincent established by the Corporation, which provided the background for production of bananas, cocoa and copra Great importance is attached to the training of men in the territories in which the Corporation operates to undertake posts of responsibility both in local projects and the Corporation's organization as a whole The Corporation believes that the best training is that received on the job provided a real effort is made to explain and demonstrate by those appointed to supervise, but in view of the absence of minimum educational background in many territories the Corporation decided last year to offer, on a very limited basis, scholarships to promising students as a contribution towards solving the educational difficulty

When the Corporation's report was discussed in the House of Lords on June 27, the Earl of Perth emphasized that in the main this was a matter which should be handled through the new Technical Aid Department, and that the Corporation should limit itself to giving training and occasional scholarships to particular people who were to work on a particular project Generally, warm approval of the work of the Corporation was expressed in the debate criticism centring rather on the Government's financial policy to the Corporation and the delay in giving effect to the recommendations of the Sinclair Report The Earl of Perth, however, mentioned that the Government had followed closely the essential recommendations regarding stock representing loans advanced for 'finance house' business and for stock representing abandoned schemes and fructification interest, but laid down that repayment for this stock should depend on the Corporation, after its various obligations, having a profit of more than £250,000 The only variation was in respect of the recommendation for '*B*' Stock, which involved a fluctuating subsidy and thus no Parliamentary control, and here the Government insisted that the agreed rate must be paid, but as these investments would be ready for equity investment the Government would continue with the fructification period for seven years The suggestion for a reserve or allowance for exploration was met by allowing the Corporation to use the first £250,000 of its true profits for whatever purpose it saw fit Lord Perth also said that it was not expected that the Corporation, which was not at the moment in need of funds, would require increasing funds indefinitely it might be expected from time to time to sell off successful ventures He thought the Corporation would still be able to play a limited part in the newly independent countries but that it was right that the Corporation should concentrate on the remaining Colonial territories

Research Schemes and Loans, 1960

The schemes made under the Colonial Development and Welfare Acts in the period April 1, 1960–March 31, 1961, which are detailed in the latest returns*, bring the total commitments from April 1, 1946, under the Acts to £275,318,622, of which £20,798,424 is for research schemes The totals for the year in question are £35,291,739 for development and welfare and £2,186,869 for research schemes Of the latter, £1,085,365 is for agriculture, £400.624 for medicine, £223,784 for tsetse research and trypanosomiasis, £150,786 for social science, £108,360 for fisheries, £56,401 for pesticides, £25,727 for locust control, and £6,803 for economic research

Of the research schemes, £446,149 is towards the cost of research organizations controlled by the East African Agriculture and Fisheries Research Council, but there are other considerable contributions to the cost of work sponsored by the Medical Research Council, the Agricultural Research Council or regional organizations, for example, £30,000 for the Medical Research Council's laboratories at Fajara, Gambia, and £11,750 for entomological research there, £133,516 for continuation of services, other than the Leprosy Research Centre controlled by the East African Council for Medical Research, 1960–63, £27,432 to the West African Council for Medical Research and its associated units, £27,103 to the West African Building Research Institute, £22,412 to the West African Institute for Trypanosomiasis Research, 1960–61, £43,320 for the Regional Virus Research Laboratory, Trinidad, £148,000 for the Regional Research Centre, Faculty of Agriculture, University College of the West Indies, and £8,000 to the Agricultural Research Council Unit of Experimental Agronomy and Weed Research Organization, 1961–62

Other major grants which may be noted are £42,827 for immunological work on trypanosomiasis and preparation of precipitin sera at the Lister

---

* Colonial Development and Welfare Act Return of Schemes made and of Loans approved under the Colonial Development and Welfare Act in the period from 1st April, 1960, to 31st March, 1961 (House of Commons Paper 240) Pp 58 (London H M S O , 1961) 3*s* 6*d* net

Institute of Preventive Medicine, £39,898 for tsetse fly breeding at the University of Bristol, £34,303 for continuation of the preparation of the Flora of Tropical East Africa, £62,933 for continuation and expansion of agricultural research and land-use planning in Tanganyika, £62,645 for the Agricultural Research and Experimental Station, Nyasaland, £56,550 for establishment of a Citrus Research Unit in the British Caribbean, £79,549 for continuation of the Institute of Social and Economic Research in the West Indies; £48,812 for the Tropical Metabolism Research Unit in Jamaica, and £20,934 for soil surveys in British Guiana

Development and welfare schemes of scientific interest include various contributions to Royal College, Nairobi, and the University College of East Africa, Makerere, as well as to the University College of the West Indies, and £450,000 for the construction of a College of Arts, Science and Technology, Malta, which received grants totalling more than £5 million during the year, £421,907 for intensification of African agriculture under the Swynnerton plan in Kenya, and a further £102,804 for the Veterinary Department, £518,300 for forestry development in Tanganyika, and £148,445 for continuation and expansion of agricultural research and land-use planning, £246,000 for development of broadcasting in Uganda, and £429,132 for soil conservation and land-use planning in Basutoland, 1960–64, £18,877 was contributed for the activities of the Commission for Technical Co-operation in Africa South of the Sahara and the Scientific Council for Africa South of the Sahara, and there were numerous contributions for education at secondary and primary levels

THE NORFOLK BROADS

On August 1, the Minister of Housing and Local Government announced in the House of Commons that he had accepted the advice of the National Parks Commission that the unique character and complex problems of the Norfolk Broads make them unsuitable for designation as a National Park It was therefore appropriate and timely that the British Association should discuss some of these problems during its Norwich meeting Sections E (Geography) and K (Botany) held a joint symposium on September 1 at which the main contributions were made by Dr Joyce Lambert of the Botany Department, University of Southampton, Mr C T Smith of the Geography Department of the University of Cambridge and Mr Charles Green, an archæological consultant to the Ministry of Works

The factors which render the Broads unsuitable as a National Park stem largely from the rapid changes which are taking place at the present time and which are all recent in effect, if not in origin The silting up of the Broads, with the consequent overgrowth by vegetation had scarcely begun to reduce the area of open water when the Tithe Commission mapped the area in the mid-nineteenth century The degeneration of mowing marsh into scrub and carr follows changes in agricultural practice in the past half-century These physiographical and ecological developments clearly have a profound significance in terms of the ever-increasing use of the Broads as a holiday area, a use which introduces its own problems, both ecological and economic While these changes have only recently forced themselves on the attention of students of the broadland scene, they are bound up with the basic problems concerning the age and origin of the Broads, which formed major themes in the Norwich discussion and which involve rather longer periods of time

Most nineteenth-century writers from Robbards and Taylor in the 1820's to Gregory in 1892, sought to interpret the Broads as residual natural lakes resulting from the silting up of a 'great estuary', the three arms of which occupied the valleys of the Rivers Waveney, Yare and Bure Many of these writers assumed that the 'great estuary' persisted well into historical times A few workers sought to invoke glacial agencies In 1952, J N Jennings published a monograph on *The Origin of the Broads* (No 2 in the Royal Geographical Society's Research Series) This was the first weighty piece of original research to appear for almost half a century and represented the results of several years labours, mainly in the valleys of the Bure and its tributary, the Ant Jennings suggested that the Broads can be explained in terms of a geologically very recent marine transgression during which a thick wedge of estuarine clay was laid down over the early valley peats of the Norfolk river valleys He suggested that the Broads themselves were initiated as discontinuous lakes, lying in natural hollows in the peat, filled with water ponded back between the flanges of the clay and the upland valley margins (by-passed broads) or in tributary valleys the mouths of which were blocked by the clay (side-valley broads) Jennings examined the possibility, mooted on several occasions to explain particular broads, that all the Broads were man-made For a variety of reasons he came to the conclusion that "a general theory based on peat cutting appears to be wholly unacceptable"

Almost before his monograph was in print, Jennings had modified his views in the light of new work. Dr Lambert, with whom he had collaborated closely in work on the valleys of the Bure and the Ant, had obtained convincing evidence that the Broads of the Yare valley are artificial She employed the same boring methods and the same pollen analysis technique, to determine the stratigraphy of the clays, peats and muds, as Jennings had used A reconsideration of the evidence from the Bure and the Ant valleys suggested that deep extraction of peat in historical times was responsible for all the by-passed broads, though, for lack of evidence, the side-valley broads were not as yet included in the general theory This recognition of the fact that most, if not all, of the Broads are man-made did not, of course, detract from Jennings's interpretation of the natural evolution of the river valleys in which the Broads are located

In 1960, Jennings and Lambert published a re-appraisal of the whole problem of the evolution of the Broads They found it "difficult, in view of the stratigraphical evidence to conceive a substantial alternative" to the theory that all the Broads are deep peat diggings which have been afterwards flooded Breydon Water is excluded from this explanation since it is clearly not a broad in the accepted sense and is merely the surviving part of a formerly more extensive Bure–Yare–Waveney estuary

Evidence from the field of historical geography assembled by Mr C T Smith and the results of archæological work, interpreted by Mr Charles Green and Mr J N Hutchinson, supported the new hypothesis The combined evidence was published under the title *The Making of the Broads* (No 3 in the Royal Geographical Society's Research Series)

At the Norwich symposium, Dr Lambert reviewed the physiographical and botanical evidence on which their findings are based Boring has revealed that the basins in which the Broads lie have uniformly steep sides and virtually level floors with resulting rectangular profiles Islands and peninsulas with similar vertical sides have exactly the same stratigraphy as the surrounding fenland They are interpreted as balks left in the extraction of peat to a depth of 10–12 ft In old surveys, including tithe and enclosure maps and in modern air photographs these islands and peninsulas can be correlated with boundaries between holdings

Two of the more important difficulties in accepting human agencies to account for the existence of the Broads relate to the enormous amount of peat involved and the need to postulate changes in water-level, which would permit the excavation of peat to depths well below those of present-day workings, and eventually lead to the flooding of the pits Mr C T Smith described the search for evidence which would resolve these difficulties Nothing in the published records of broadland suggested an 'artificial' origin The large-scale changes caused by the extraction of an estimated nine hundred million cubic feet of peat and the flooding of the workings appear to have made no impact on local tradition and folk-lore However, a careful and detailed study of documents and maps supplied strong circumstantial evidence in support of the deductions based on the stratigraphy References to turbary and the sale and consumption of turves show that large-scale peat digging was well under way by the twelfth century Much of the consumption must have gone unrecorded but examination of terriers, deeds, account rolls and registers, such as those of Norwich Cathedral Priory and St. Benet's Abbey, give an indication of the scale of operations. The purchase of 400,000 turves by Norwich Cathedral Priory in 1316 is typical These same records also show that by the beginning of the fourteenth century the flooding of the turf pits had begun While extraction continued well into the fifteenth century it was increasingly difficult and expensive, and involved first the dredging of peat with simple scoops and then the making of turves Soon other fuels replaced turves in the records and references to turbaries were replaced by references to open water and fisheries.

The archæological evidence put forward by Mr Charles Green showed that emergence from the Romano–British submergence reached a peak in the thirteenth century. The excavations on the site of the power-station at South Denes, Great Yarmouth, indicate a relative fall in sea-level of the order of 13 ft This means that deep extraction of peat from the Norfolk valley floors was possible in 'dry' pits Similar evidence revealed a reversal of the downward movement of sea-level, initiated toward the end of the thirteenth century, which clearly accounts for the slow but inexorable flooding of the peat-diggings and the formation of what we now call the Norfolk Broads

As a piece of scientific detection, the story unfolded to the Norwich symposium was a masterpiece It is, however, not only of historical or academic interest The state of dynamic change, which Dr Lambert showed to underlie all the present-day problems of the Broads, both scientific and practical, stems directly from these surprising beginnings The vegetation of broadland does not, as was formerly thought, result from the overgrowing of large continuous sheets of open water There is a fundamental distinction between the vegetation which has grown up on the solid fen, much modified by a variety of human interference, and that which is encroaching on the basin of the Broads. The filling of the man-made lakes with freshwater mud, which has made this encroachment possible, only reached a critical stage about the beginning of the nineteenth century It has, however, already resulted in a rapid reduction of the open water available to the holiday maker Dr Lambert is continuing her ecological work in the Broads, but the number of problems which still remain to be tackled, some of which she touched on, is very large The need for more research was the theme of the discussion which followed the reading of papers Any new work which may be instituted will owe much to Dr Lambert and Mr Jennings and their colleagues

C KIDSON

THE SOIL AS AN ENVIRONMENT FOR ANIMAL LIFE

A SYMPOSIUM on "The Soil as an Environment for Animal Life" was held on September 1 by Section D (Zoology) at the Norwich meeting of the British Association for the Advancement of Science

Sir John Russell pointed out that soil contains four groups of components a mineral framework, organic matter, mineral matter from the bodies of organisms and soil solution. The relative proportions of organic and inorganic substances largely determine the suitability of the soil as a habitat arable soils, with the lowest organic content, contain fewest organisms, while grasslands are usually richer

The organic matter is derived from plants, their remains being reduced by organisms in the soil to their original simple origins residues remaining form the humus. This is black, has colloidal properties, and in the climate of Great Britain contains about ten times as much carbon as nitrogen If non-nitrogenous substances are added to the soil, atmospheric nitrogen is fixed, while if nitrogenous substances are added the humus splits off nitrogen as ammonia or nitrogen gas

The mineral framework of the soil contains particles ranging from 2 mm to 0 02 mm in equivalent diameter these are the sand and silt Clay particles less than 2μ in equivalent diameter differ from the larger particles, they carry a negative electric charge, and can attract positively charged ions such as calcium and hold them against leaching Clay is colloidal, with a great power of absorbing water it expands on wetting and shrinks on drying, producing large cracks in the soil

Calcium compounds, especially calcium carbonate, are as important as clay and organic matter in their biotic effects While calcium carbonate is present the soil remains neutral, but as it dissolves in rain-water containing carbon dioxide and is leached out the soil becomes acid The flora and fauna then become more restricted, though some organisms, such as *Plasmodiophora* and the amœbæ, do well At a certain stage earthworms disappear plant residues then remain on the surface and decompose there, forming 'mor'

Organic and mineral soil components mingle to form crumbs, the optimum crumb size for plant growth ranging from 5 to 1 mm Good crumbs are stable even under rainfall, while bad ones break down in wet conditions, forming a slurry Mineral particles and crumbs have pore spaces between them, the total pore space being increased by crumb formation

For organisms to survive in the soil, five conditions are necessary living space, air, water, suitable temperature and freedom from injurious factors The pore spaces provide the living room, and are also the water reservoirs The chief cause of water loss is suction by plant roots evaporation causes less than might be supposed The surface layer dries quickly and protects the soil beneath, and there is no evidence of capillary movement of water from wetter to drier parts except just above the water table

Diffusion of air into the pore spaces is very rapid, and the composition of air 6 in down on arable land differs little from that of the atmosphere, except that the amount of carbon dioxide is greater, reaching 0 1 per cent on bare soil and 0 2 per cent under crops In grassland soil the carbon dioxide content is greater 3 per cent has been recorded This high concentration does not appear to affect the soil population seriously

Soil temperatures reflect those of the air, but fluctuations are heavily damped Variations are greater on arable land than on grassland

Harmful factors are numerous and may be drastic These include acids, products of anaerobic decomposition such as hydrogen sulphide, the presence of parasites and predators, etc Soil bacteria act as scavengers, removing harmful substances very effectively

The question of food for the soil fauna has been studied most fully by the foresters Leaves and twigs form litter on the soil surface in it a mixed population develops and makes the primary attack on the food material it contains Then follows the secondary decomposition, in which organisms nurtured in the first stage are eaten by predators that either capture their prey or poison it and feed on its decomposing body, also the excretions of primary decomposers are eaten by coprophagous animals The final residue is humus, this persists in the soil, but is slowly decomposed, mainly by bacteria, the final end-products being carbon dioxide, ammonia, water and a few mineral salts These will be starting material for a new generation of plants

Dr F Raw discussed "The Interdependence of the Soil and its Fauna" The soil can be considered an environment created by animal activity from weathered mineral substrate and plant remains The material from which the soil developed, the climate and the vegetation influence the animal communities developing in the soil, and these in turn influence the soil profile Agricultural practices that affect the fauna may produce great changes in the biological and physical properties of the soil

The greatest diversity and abundance of soil animals are found in virgin habitats such as permanent grassland or woodland The arthropods in a permanent grass field in Cambridgeshire included 17 orders or classes, including uncommon groups such as the Pauropoda and Protura Smaller arthropods were especially numerous About 70 per cent of the Arthropoda occurred in the top 6 in, though some groups were more numerous at lower levels In general, the smaller forms live deeper in the soil

In arable soil the arthropod population is greatly reduced In the Barnfield mangold plots at Rothamsted, the plots receiving mineral fertilizers yielded about 15,000 individuals per square yard, while in the dunged plots the number of individuals was almost twice as great, and the population was more diverse The same was true of the earthworms, though the dominant *Lumbricus terrestris* was less affected by dunging than other species

Earthworms are the principal agents that bury plant remains, mix them with the soil and so accelerate decomposition and the release of plant nutrients In undisturbed habitats their activity can have a profound effect on the soil profile, and their presence or absence can result in the development of two fundamentally different soil types, 'mull' and 'mor' This was illustrated by measuring the amount of leaf litter buried by worms in several apple orchards near Wisbech, by placing a known number of weighed leaves on the ground beneath wire cages at leaf-fall and recording the number and weight of leaves remaining in the spring In grass orchards the number and weight of leaves buried was closely correlated with the estimated fresh weight of *Lumbricus terrestris* Some orchards had about 20 cwt of *L terrestris* per acre, which buried 8–9 cwt dry weight of leaves—enough to bury all the leaf-fall Cultivation did not appear to affect the abundance of *L terrestris* greatly nor did regular applications of farmyard manure or compost

In a grass orchard with a long history of heavy spraying with copper fungicides *L terrestris* was not found, although it was abundant in surrounding unsprayed soil In this orchard no leaves were buried, they decomposed slowly on the surface, and a mat of partially decomposed leaves, about 2 in thick, had accumulated, so that the soil profile had typical 'mor' characteristics

"The Soil Fauna and its Contribution to Fertility" was the subject of Dr A Macfadyen's paper The soil contains enormous numbers of individual animals, and their action appears to be three-fold The larger species tunnel through the soil and carry litter downwards and mineral matter upwards at the same time they aerate and drain the soil and, by crumb formation and in other ways, render it a good medium for the growth of higher plants and micro-organisms

The second function performed by the soil animals is a direct chemical one due to their feeding activities They assist in the breakdown of litter in the soil, though here they make a poor showing compared with the micro-organisms

The third property of the soil fauna has only recently come under investigation It appears that quite apart from their own direct metabolic effects on litter breakdown, soil animals act as catalysts of the metabolism of the bacteria, fungi and other micro-organisms This catalytic action appears to operate through the cropping of senescent colonies, the re-distribution of slow-moving food materials, the local removal of antibiotic substances, the re-concentration of nutrients and the spreading of spores to places where they can flourish. The biological properties of the microbes are such that high-energy food materials become inaccessible and energy becomes dammed up. The animals are the 'dam-busters' that disperse the accumulations of energy and restore the flow—and with it the nutrients needed by the higher plants.

It is not known yet how important these catalytic actions are, nor which of them are the most significant. Clearly, over the whole range of soil types, from forest and pasture to moorland and degraded arable land, the details of the picture are going to vary enormously, but the few experiments reported indicate that the animals' 'catalytic' role greatly exceeds their metabolic role as decomposers.

Current experiments are aimed at building up a good knowledge of the metabolic rates of isolated organisms under conditions as close to those in Nature as possible. At the same time systems are being developed containing micro-organisms and essential soil constituents of varying degrees of complexity but with predictable metabolic behaviour. It is hoped to go on from there to introduce different kinds of animals into the cultures and observe their effects on total metabolism, and to analyse the biochemical basis of these effects. In this way it is planned to bridge the gap between field conditions and laboratory experiments.

Dr. C. L. Duddington discussed "Predacious Fungi and Soil Eelworms". Predacious fungi are micro-fungi that attack small animals, including protozoa, rotifiers and eelworms. They are abundant in most fertile soils. We can distinguish two kinds of predacious activity among the fungi that attack eelworms. Some capture eelworms alive, while others are internally parasitic, attacking the host through the agency of sticky spores or by other means. At least two species of *Nematoctonus* combine both methods. Most of the work on predacious fungi attacking eelworms has been concentrated on the trap-forming species.

In the common *Arthrobotrys oligospora* and others the eelworm traps consist of systems of sticky networks, formed from curled, anastomosing branches of the mycelium. Eelworms that happen to touch the networks stick to them like flies on a fly-paper. Other species, like *Dactylella cionopaga*, have short, sticky lateral branches, while in *D. ellipsospora* and others small sticky knobs are attached to the mycelium by short stalks.

Some predacious fungi have mechanical traps. In *Dactylaria candida* rings, composed of three curved cells, are attached to the mycelium by short stalks, eelworms accidentally pushing their heads into the rings become wedged. In some species, such as *Dactylella doedycoides*, the cells of the rings are sensitive to touch, if an eelworm passes its body into the ring the three cells swell suddenly inwards, holding the eelworm by constriction.

Whatever trapping mechanism is used, the end result is that the eelworm is killed, and its body is invaded by hyphæ that consume its contents.

A survey of 49 British arable soils produced 82 records of predacious fungi, belonging to 20 different species. *Arthrobotrys oligospora* was the commonest; both eelworm-trapping and internally parasitic species were represented. There is direct evidence that predacious fungi prey on eelworms in the soil under natural conditions, for mycelium with traps and captives has been found on slides immersed in soil both in field plots and in the laboratory. There is also convincing evidence that their predacious activity is enhanced by the presence of decomposable organic matter in the soil. There is reason to believe that the organic matter affects the activity of the fungi directly and not, as has formerly been supposed, through its stimulating effect on the population of free-living eelworms in the soil.

The importance of predacious fungi in limiting the soil nematode population under natural conditions has yet to be fully investigated, but experiments on the use of predacious fungi for the biological control of plant pathogenic eelworms suggest that their effect is not negligible. Soil treatment designed to enhance the activity of predacious fungi was successful in controlling pineapple root-knot eelworm in Hawaii, and in Britain the number of larvæ of cereal root eelworm invading the roots of oat seedlings has been significantly reduced by soil inoculation with *Dactylella thaumasia* combined with the addition of organic matter to stimulate the fungus.

C. L. DUDDINGTON

DOMESTIC FOOD CONSUMPTION AND EXPENDITURE, 1959

THE survey for 1959 of the National Food Survey Committee* completes twenty years of continuous recording of domestic food consumption in Britain. Two reports cover the years 1940–49 and since 1950 a report has been published each year. These twenty years have seen a complete change from severe restriction in food supplies, followed by a period of gradual increase, to the point recently reached at which the housewife with money to spare looks for greater variety and shows a preference for what may be called 'convenience foods', processed and packed to save time and trouble.

A gap necessarily intervenes between the year of survey and the publication of these annual reports. As a result, they often clarify and extend facts already known in a general way. For example, the present report throws light on the increase in expenditure on food known to be taking place during the period under review. The average weekly expenditure a head increased from 28*s.* 5*d.* in 1958 to 29*s.* 3*d.* in 1959. This was partly due to an increase in the price of foods such as butter, meat, cheese and fruit, but there was also a shift in demand from staple foods such as bread, flour, potatoes and fresh fish to fresh fruit, fresh green vegetables and a wide variety of processed foods. Expenditure on processed foods prepared ready for the table, which include canned and frozen foods, cakes, pastries and biscuits, has risen from 4*s.* 3*d.* a head a week in 1955 to 5*s.* 5*d.* in 1959. Doubtless, as the range of such foods increases and advertising becomes more clamorous, the expenditure on them will continue to rise, though a certain lack of variety in the taste of foods prepared by mass-cooking methods may eventually drive some housewives back to the kitchen stove In the section dealing with the effect of the housewife's age on the household diet, it is shown that young housewives devote up to 19–24 per cent of their total food expenditure to these 'convenience' foods, while older housewives devote considerably less The fact that 'single-earner' families with two children spend more on them than childless couples shows how useful they can be to the busy mother Their cost in terms of food is increased by packaging and advertising, but this is offset by saving in time and less wastage The expenditure on cooked and canned meats rose 5 per cent from the previous year, and on prepared fish the rise was 14 per cent The most striking change in food habits in Britain, apart from the growing preference for processed foods, is the increase in consumption of poultry Total supplies of poultry and rabbits are 31 per cent higher than pre-war, although there has been a considerable decrease in supplies of rabbit

* Ministry of Agriculture, Fisheries and Food. Domestic Food Consumption and Expenditure 1959. Annual Report of the National Food Survey Committee. Pp. vi+142. (London: H.M.S.O., 1961.) 8*s.* 6*d.* net.

Comparison of the nutritive value of the diets of the different social classes with the recommendations of the British Medical Association showed that intakes of all nutrients, except protein, considerably exceeded the figures of the British Medical Association Total protein intakes were 'borderline' in the lower income groups and the national average 99 per cent of the recommendation of the Association As income rises, the calorie value of diets and their content of all the nutrients also rises The diet of the most prosperous classes is 'richer' in these respects than that of all other classes This perhaps suggests that wealthy people eat too much, but on the other hand it might be taken to imply that the recommended allowances are set too low Such questions could be clarified only by correlating national food consumption data with data on the health of different sections of the population—an extremely difficult task

Study of the relation between food consumption and family composition and size gave a less favourable picture In households containing four or more children the diets were inadequate in certain respects Intake of calories was 94 per cent of the recommended level, and that of protein, calcium and riboflavin 82, 81 and 95 per cent respectively These deficiencies may not seem great, but it must be remembered that these families contain a high proportion of growing children whose health and development depend largely on proper feeding At the other end of the life-scale an improvement is recorded In earlier reports it was shown that the diets of old age pensioners were unsatisfactory , it is good to note that their diets included in this survey were adequate for all nutrients

Interesting facts are given about geographical differences in food consumption These give rise to many fascinating speculations on feeding and cooking habits in different parts of Britain, but it would be foolhardy to hazard guesses on the merits and efficiency of housewives according to locality

JOYCE DOUGHTY

NITROGEN IN SHEEP SALIVA

IN a series of articles, M Somers, of the Institute of Agriculture, University of Western Australia, describes the factors influencing the secretion of nitrogen in sheep saliva (*Austral J Exp Biol and Med Sci* , 39, Part 2, April 1961)

Measurements were first made on the distribution of nitrogen in the mixed and parotid salivary secretion of sheep and on the amount of nitrogen secreted daily in the parotid saliva The distribution of nitrogen in the mixed saliva followed the same pattern as that in the parotid secretions obtained when the glands were in a quiescent state The concentration of nitrogen in both fluids depended on the rate of secretion Although the concentration of total nitrogen in the mixed and parotid saliva increased during short-term stimulation, the pattern of nitrogen distribution was not affected During prolonged stimulation of the parotid glands, the nitrogen composition of the saliva changed

Quantitatively, urea was the most important nitrogen compound in both the mixed and parotid saliva, accounting for 60–70 per cent of total nitrogen The average volume of saliva secreted daily by one parotid gland was 2,380 ± 43 8 ml and the average total nitrogen content was 295 5 ± 5 77 mgm when the nitrogen intake was 14 8 gm /day

Somers later examined the influence of nitrogen intake on blood urea nitrogen and on the total nitrogen and urea nitrogen in the parotid saliva of sheep Urea was added to the rumen of three merino sheep at the rates of 5, 10 and 20 gm daily to increase the overall nitrogen intakes from 10 7 gm in the basal ration to 13 0, 15 4 and 20 0 gm a day A marked increase in the total amount of nitrogen secreted in the parotid saliva was found to occur as the nitrogen intake of the sheep increased A similar high correlation was found between the level of nitrogen intake and the amount of urea nitrogen secreted in the saliva daily

Between the highest and the lowest levels of nitrogen intake the magnitude of the increases were 0 26 gm of total nitrogen and 0 18 gm. of urea nitrogen/gland/day The concentration of urea nitrogen in the blood increased with the level of nitrogen intake of the sheep, but fluctuations in the level of blood urea could not be accounted for by nitrogen intake alone A significant correlation was found between the concentrations of urea nitrogen in the blood and in the saliva This offered a partial explanation of the higher concentrations of salivary urea resulting from the increased nitrogen intakes

Further investigations were made of the factors affecting the nitrogen fractions in the parotid saliva of sheep with special reference to the influence of production of ammonia in the rumen and fluctuations in level of blood urea Quantitative measurements were made on the volume of saliva secreted hourly by the parotid glands of Merino sheep over a period of 24 hr on three separate days At the same time fluctuations in the concentration of urea and total nitrogen in the saliva were studied in relation to the production of ammonia in the rumen and changes in the level of blood urea which occurred throughout the day

Levels of both rumen ammonia and blood urea followed a relatively simple cyclical pattern over each 24-hr period However, two distinct phases were apparent in the salivary nitrogen cycle The first, a short phase, followed the changes in stimulation associated with eating The second phase was prolonged and more complex It was influenced by changes in the level of blood urea, but additional factors also operated in the second phase

Finally, Somers examined the influence of injected urea on the quantitative recovery of urea in the parotid saliva and the urinary excretions of sheep Differential responses occurred in the amount of urea nitrogen and total nitrogen secreted in the parotid saliva, according to the nitrogen status of the sheep, when 1 4 gm of urea nitrogen was injected into the blood daily Of this amount of nitrogen, 0 1 gm could be recovered in the secretion from one parotid gland daily when the sheep were in positive nitrogen balance, and 0 3 gm when the sheep were in negative nitrogen balance The urinary excretion accounted for 1 0 gm of the 1 4 gm of urea nitrogen injected daily when the sheep were in positive nitrogen balance, but only 0 3 gm /day at the lower nitrogen status The implications of these findings have been considered in relation to a urea conservation mechanism in sheep

CEREBRAL INFARCTION

IN 1959, in England and Wales, cerebrovascular disease was the certified cause of 75,150 deaths (14 per cent of the total mortality), and, according to the Registrar General's analysis, about half these were a direct result of infarction of the brain The morbidity associated with this disease is also formidable, death may be preceded by months or even years of mental deterioration or paralysis

For more than a century autopsies on cases of cerebral infarction have revealed frequently an unexpected absence of significant lesions in the local cerebral arteries, and attention has periodically been directed to the possible role of the carotid arteries in this condition In a study by Dr Peter Yates and Dr E F Hutchinson on behalf of the Medical Research Council, 100 cases of suspected cerebral ischæmia were investigated in detail *post mortem*, and in 35 of these cerebral infarction was found[*] The whole course of the cerebrovascular tree from the aorta to the brain was examined, the vertebral as well as the carotid arteries being dissected, and the pathological findings were correlated with clinical records, Dr Yates was mainly concerned with the pathological side of the work, and Dr Hutchinson with the clinical aspects

Of the cases of cerebral infarction, little more than half showed occlusion or significant narrowing of the local arteries, but serious obstructions of the extracranial cerebral arteries was found in 90 per cent Such a high frequency of extracranial arterial obstruction in cases of cerebral infarction suggests that surgery may have a wider application in the early stages of cerebrovascular disease than has been generally recognized

The authors emphasize, however, that cerebral infarction rarely has a single cause, and that it is usually the result both of obstruction in extracranial or intracranial cerebral arteries and of systemic disease The decisive part played by general systemic factors, especially those that result in a lowering of the blood pressure, is amply shown in this report Even when cerebral arteries, whether extracranial or intracranial, are grossly narrowed, the blood circulation in the brain may be maintained for long periods, provided that there is an adequate collateral supply, but if hypertension or anæmia occurs in addition, the precarious balance may be upset and cerebral infarction precipitated

STANFORD–PACIFIC NAVAL LABORATORY CONJUGATE POINT EXPERIMENT

By J. E LOKKEN, J. A SHAND and Sir C. S WRIGHT, K C B , O.B.E.
Pacific Naval Laboratory, Esquimalt, British Columbia
AND
L. H. MARTIN, N. M. BRICE and R. A. HELLIWELL
Radioscience Laboratory, Stanford, California

A CLOSE correlation has been discovered in the times of occurrence of very low frequency and extra low frequency electromagnetic phenomena observed at high-latitude conjugate locations The observations were carried out jointly by the Pacific Naval Laboratory of the Defence Research Board of Canada and the Radioscience Laboratory of Stanford University during January 1961. For this experiment the Pacific Naval Laboratory extended the range of its 0 003–3 c p s investigations of geomagnetic micropulsations to include the natural electromagnetic background up to about 30 c p s Similarly, Stanford very low frequency investigations were broadened to cover from 15,000 c p s down to about 5 c p s Combined observations were made at Byrd Station, Antarctica (80° S , 120° W), and at two near conjugate locations in the vicinity of Hudson Bay in the Canadian Arctic The nearest, 200 miles south of the conjugate point on the Vestine model, was at Great Whale River, 55° 17′ N , 77° 46′ W , and the other at Fort Churchill, 58° 42′ N , 94° 03′ W , some 500 miles west of the conjugate point The geomagnetic co-ordin-

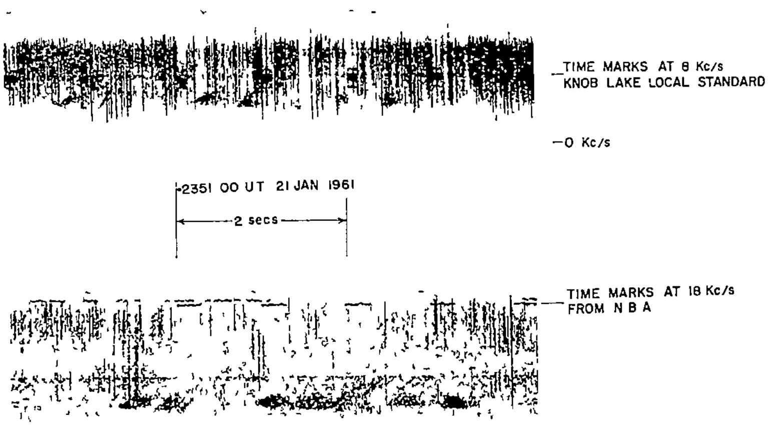

Fig 1 Six bursts of noise in the 5–6 kc p s frequency region appearing at Knob Lake (above), and at Byrd Station about 0 8 sec later (below)

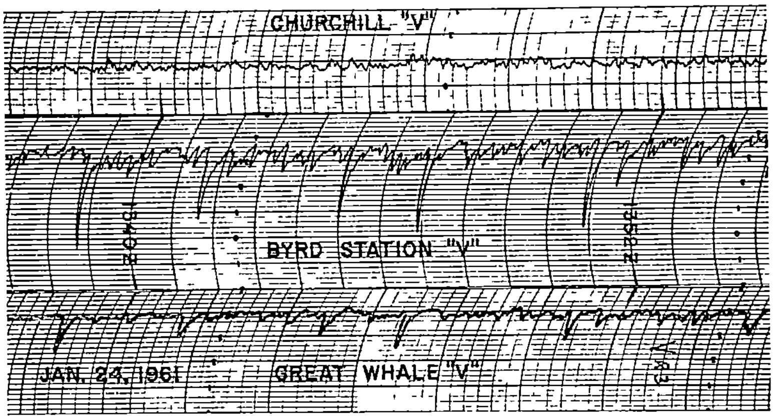

Fig 2 Envelopes of the activity received on the 2–30 c p s (V) system at three auroral stations The record for Churchill is in inverted relation to the other two

ates of these stations are 70 4° S , 337 5° E , 67 8° N , 350° E , and 68 7° N , 322 8° E , respectively

Stanford very low frequency equipment consisted essentially of a vertical single-turn loop antenna with an effective area of 80 square metres, coupled to a broad-band audio-frequency amplifier[1] The signals were recorded on magnetic tape Observations were made at synoptic intervals of 2 min each hour so that later comparison could be made with data from the various stations of the Whistlers-East and Whistlers-West networks Of particular interest in this regard were the observations made at Knob Lake, Canada, 67 5° N , 1° E geomagnetic, some 400 miles south-east of the Vestine point conjugate to Byrd Station These records were kindly loaned by Dr M G Morgan Observations taken at points along the magnetic meridian passing through Byrd Station (very low frequency traverse) were also available

Pacific Naval Laboratory equipment[2] at the conjugate stations consisted of multi-turn mumetal strip-cored detectors oriented to measure the geomagnetic fluctuations between 0 003 and 3 c p s in the conventional *X*, *Y* and *Z* geographical axes At pre-arranged times the *X*, *Y* and *Z* detectors at these stations were sharply tuned to one of four frequencies (0 8, 1 1, 1 6 or 2 2 c p s) Single components were monitored at Ottawa and Victoria In addition, signals in the 2–30 c p s bands were received on horizontal two-turn loops of 3,000 ft circumference The *X*, *Y* and *Z* outputs and the envelope of the 2–30 c p s band were continuously recorded on Esterline-Angus charts, and magnetic tape records were made at pre-arranged intervals

Analysis of synoptic very low frequency records taken at Byrd Station and Knob Lake has shown that various strong bands of very low frequency emission activity in the 200–1,200 c p s range are often present at the same times Table 1 shows the correlation coefficients versus frequency calculated from simultaneous intensity measurements It was found that the emission bands showing a distinct lower frequency cut-off at Byrd Station appeared more frequently at Knob Lake than those bands showing no distinct lower border Discrete bands of very low frequency emissions were also often closely related Fig 1 shows a sample of the close correlation in time and character of noise bursts at about 5 kc p s as observed at Byrd Station and Knob Lake The emissions shown arrive at Knob Lake 0 8 ± 0 1 sec prior to their appearance at Byrd Station Timing at both Byrd and Knob Lake was measured independently, utilizing the time pips from Station *NBA* so that the only significant limitation on the accuracy of the measurements is the lack of definition of the emissions themselves (Typical whistler time delays at 5 kc p s for one traverse of the path at these latitudes lie between 1 5 and 2 5 sec)

Signals recorded in the 2–30 c p s range also show close conjugate correlation Fig 2 shows a comparison of the envelopes taken at Byrd, Great Whale and Churchill It can be seen that the first two have a higher degree of correlation, not only of the bursts in amplitude, but also in much of the detailed structure between the bursts

Although only a few magnetic tapes of these extra low frequency signals have been analysed to determine the spectral composition, it seems that four distinct and independent bands of noise are often present These bands are usually centred about 8, 14 and 20 c p s , and one, more variable than the others, centred between 25 and 30 c p s The bands centred about 8 c p s and 14 c p s predominate (Fig 3) and are found at all three auroral stations The amplitude bursts in Fig 2 are associated with enhancements in the lower frequency bands, usually 8 c p s It seems probable that each band is made

Table 1 SPEARMAN RANK CORRELATION COEFFICIENT VERSUS FREQUENCY FOR 48 CONSECUTIVE HOURLY SAMPLES OF VERY LOW FREQUENCY NOISE AT BYRD AND KNOB LAKE

Frequency in c p s	200	300	400	500	700	1,000	2,000	3,000	4,500	7,000	10,000
Correlation coefficient	+0 46	+0 48	+0 51	+0 59	+0 48	+0 52	+0 14	+0 04	+0 26	+0 30	+0 17

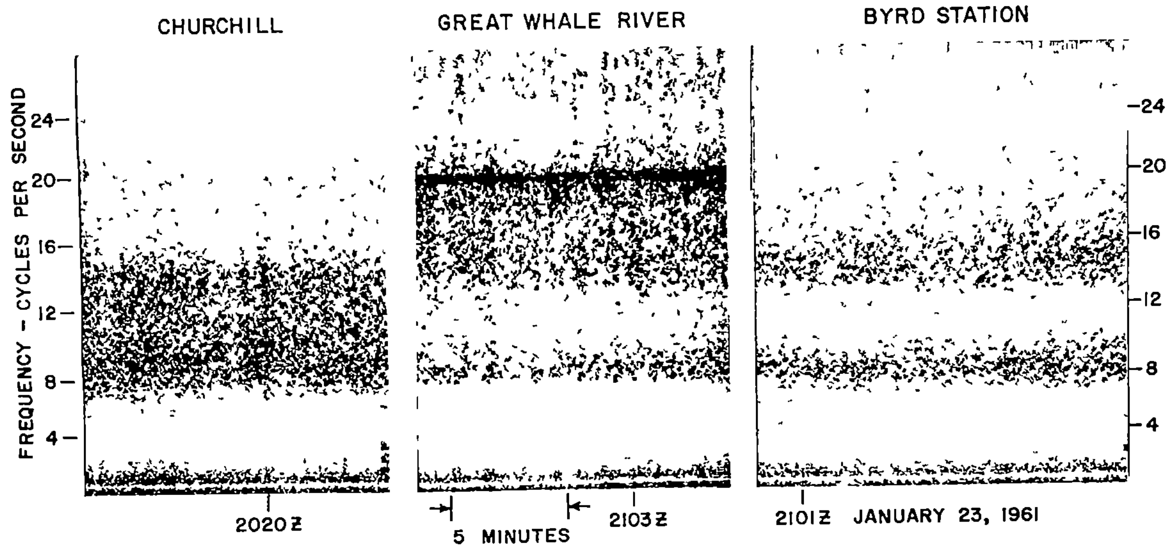

Fig 3 The spectral distribution of signals received by the 2–30 c p s system at three auroral stations at nearly similar times The narrow band near 20 c p s at Great Whale River is of undetermined origin

up of a multitude of discrete signals, similar to 'chorus' in the very low frequency regions In the frequency-range below 30 c p s world-wide lightning is a chief source of noise received on a vertical loop However, lightning does not appear to contribute substantially to signals received on the horizontal loop

In the micropulsation-range (0 02–3 c p s), although activity at the auroral stations was significantly more complex, during undisturbed times all stations often showed a marked similarity Enhancements of activity accompanied by visible auroræ usually showed a closer relationship in time and character between Great Whale River and its near conjugate at Byrd Station than between any other pair Auroræ were, of course, not visible in the antarctic summer, but from the character of the micropulsation records they were probably present Enhancements due to geomagnetic activity associated with sudden increase on ordinary magnetograms were received by the 2–30 c p s equipment on several occasions These were generally due to frequencies well below 2 c p s which were of large amplitude and usually coincident within 2 min at Byrd Station and Great Whale, while their occurrence and timing were often more independent at Churchill

It seems that the similarity of records taken at Great Whale and Byrd results from their close conjugate relationship This view is supported by the generally lower correlation of Churchill with Great Whale and Byrd Very low frequency observations taken in the Antarctic show little correlation of activity below 3 kc p s at stations 1,200 km apart (Byrd Station and South Pole Station), and results from the very low frequency traverse indicate that at these frequencies significant differences between simultaneous recordings appear at distances of 200 km Although this suggests that much of the very low frequency emission activity observed in the auroral regions may be initiated in the lower ionosphere, it does not exclude the possibility that these emissions may be generated at a much greater height The small time difference between the occurrence of identical events at opposite ends of a field line suggests that these events may result from particles impinging on the Earth's magnetic field not far from the equatorial plane

This work was supported in part by National Science Foundation grant 13532 and partly by the Defence Research Board of Canada under Project *D*45-95-11-39

INTERPLANETARY DUST NEAR THE EARTH*

By Prof. S F. SINGER

Department of Physics, University of Maryland

THE problem of gravitational accretion of interplanetary dust[1–3] by a planet has recently been the subject of renewed attention In particular, the possibility of observing dust impacts experimentally at various distances from the centre of the Earth by means of rockets, satellites and space probes has stimulated an inquiry into the concentration of dust around the Earth[4,5] Beard[4] has predicted that the dust concentration should increase as the inverse 3/2 power of distance, that is, as $r^{-3/2}$, and by a factor of 10^3 over the value in interplanetary space Whipple[6] has recently published a compilation of rocket and satellite data which exhibits a rapid increase of counting-rate as the Earth is approached, by about

* Substance of a paper at the Spring Meeting of the American Geophysical Union, Washington, D C, April 1961

10^5 He identifies this phenomenon with the existence of a permanent 'dust belt' around the Earth

The purpose of the present article is to point out that a more complete theory does not lead to a continuous increase in dust concentration as Earth is approached, but rather to a maximum at about 2,000–3,000 km above sea-level, giving rise to a 'dust shell' The increase amounts to a few times the value of the concentration of dust in interplanetary space, rather than a factor of 1,000 as given by Beard[4,7] However, since detectors do not measure concentration, but instead count particles having a certain momentum above a minimum value, the expected increase in counting-rate as one approaches the Earth is in fact larger, but still not in accord with Whipple's compilation We are therefore left with the conclusion (1) that other factors besides gravitational enhancement take a role in a proper theory, for example, particles in captured orbits[5,6,8], or (2) that the variations with time in the intensity of the dust particles are very strong so that this effect must be taken into account in assembling a compilation

First I will neglect all forces except gravitational forces, hence, the results given here apply to large dust particles, certainly for dust particles of the order of 100 microns (For smaller dust particles radiation pressure forces must be considered, as well as force arising from the electric charge of the particle, notably the Lorentz force and Coulomb drag[8]) It is assumed that the geocentric velocities of these dust particles are isotropically distributed This means that at large distances from the Earth, where the gravitational potential due to it is negligible, the particles have randomly oriented velocities with respect to the Earth Furthermore, these velocities are small, of the order of a few km per sec This conclusion is arrived at by considering the action of the Poynting–Robertson effect on the orbits of small dust particles[2,9]

The following notation is used distances r are measured in terms of R, the radius of the planet, denoting $y = R/r$, velocities are measured in terms of $v_\infty = (2GM/R)^{1/2}$, the escape velocity from the surface of the planet The energy ratio (GMm/R) to $(\frac{1}{2} mu^2)$, where u is the (geocentric) velocity at infinity of the particle, will be denoted by E Thus

$$E = 2GM/Ru^2 = v_\infty{}^2/u^2 \qquad (1)$$

From conservation of energy it follows that

$$\tfrac{1}{2} mv^2 = \tfrac{1}{2} mu^2 + GMm/r \qquad (2)$$

Hence

$$v^2 = u^2 + v_\infty{}^2 y \qquad (3)$$

At a level determined by r, the speed of the particle is defined by equation (3) The allowed directions are defined as follows at any point r (i) particles incident with zenith angle θ between 0 and a certain value θ_c become accreted by the planet and therefore contribute to the density only when moving towards the planet, (ii) particles incident with θ between θ_c and $\pi/2$ return again to infinity and therefore contribute twice

The angle θ_c corresponds to the trajectory which grazes the surface of the planet Hence, by conservation of angular momentum

$$rv \sin \theta_c = Rv_R \qquad (4)$$

where

$$v_R{}^2 = u^2 + v_\infty{}^2$$

Hence

$$\sin^2 \theta_c = y^2 \frac{u^2 + v_\infty{}^2}{u^2 + v_\infty{}^2 y} \qquad (5)$$

I now make the reasonable assumption that the geocentric velocities u of the particles are isotropically distributed, that is, they are at large distances from the Earth I also take a unique value of u, although my approach can be generalized in a straightforward manner to deal with a distribution of velocity values

Since by Liouville's theorem the phase space density D remains constant, the density ρ at r will be given by

$$\rho(r) = c[\int_0^{\theta_c} v \sin \theta \, d\theta + 2\int_{\theta_c}^{\pi/2} v \sin\theta \, d\theta]$$
$$= C(u^2 + v_\infty{}^2 y)^{1/2} (1 + \cos \theta_c) \qquad (6)$$

With the help of equation (5)

$$\rho(r) = C(u^2 + v_\infty{}^2 y)^{1/2} \left[1 + \left(1 - y^2 \frac{u^2 + v_\infty{}^2}{u^2 + v_\infty{}^2 y}\right)^{1/2}\right] \qquad (7)$$

The normalization constant is obtained by setting $y = 0$

$$\rho_\infty = 2Cu$$

If all velocities are now expressed in terms of v_∞, then

$$\frac{\rho(y)}{\rho_\infty} = \left(\frac{u^2 + y}{4u^2}\right)^{1/2}\left[1 + \left(1 - y^2 \frac{u^2 + 1}{u^2 + y}\right)^{1/2}\right] \qquad (8)$$

The function is plotted in Fig 1 and shows some extremely interesting features. In the first place, it is seen that the density in cislunar space, in particular close to the Earth, is always enhanced over the density in interplanetary space The enhancement is particularly pronounced for small values of u The remarkable feature, however, is the fact that a pronounced peak exists always above the atmosphere

When u exceeds $3^{-1/2}$ the density ρ_R very close to the Earth drops below the free-space density This can be seen more clearly by setting $y = 1$ in equation (8) Hence

$$\rho_R/\rho_\infty = [(u^2 + 1)/4u^2]^{1/2} \qquad (9)$$

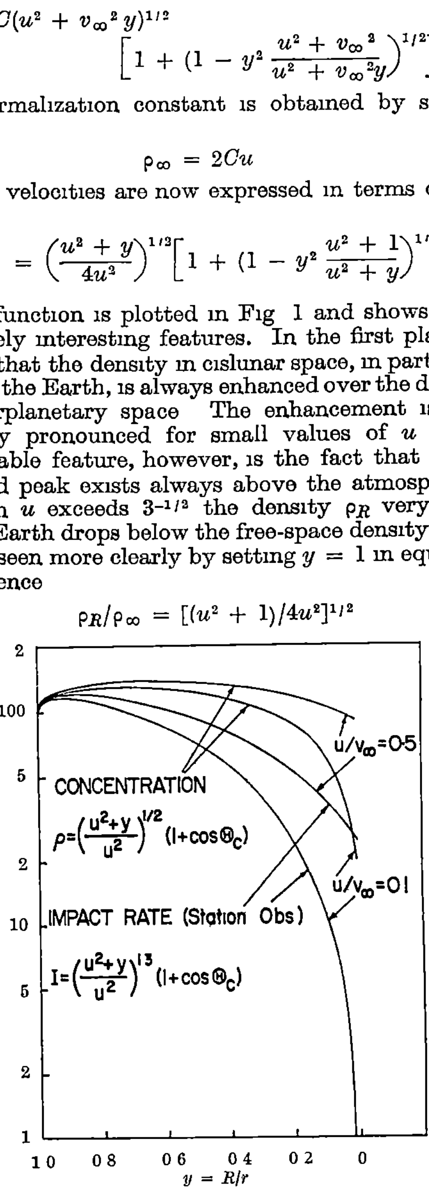

Fig 1 Concentration of zodiacal dust as a function of distance from the centre of the Earth Also plotted is the impact-rate which would be observed by an instrument moving at very low speed with respect to the Earth (case 1) The graphs convey the spread to be expected with geocentric velocities of the zodiacal dust in interplanetary space of about 1–5 km per sec

which for small values of u reduces to $(2u)^{-1}$ and for large values of u to 1/2.

For small values of u also equation (8) can be replaced by

$$\rho(y)/\rho_\infty = (2u)^{-1}\, y^{1/2}\,[1 + (1 - y)^{1/2}] = \rho_R\, y^{1/2}\,[1 + (1 - y)^{1/2}] \qquad (10)$$

We can investigate the remainder of the expression (10). It reduces to 1 at $y = 1$. If we replace y by $1 - \varepsilon$, then the expression reduces to $1 + \varepsilon^{1/2}$. Therefore, we see that there is always a peak below $y = 1$, and therefore at some altitude above sea-level. This peak is produced by a 'shadow effect' of the planet.

The rate at which dust particles are accreted by the Earth can also be investigated; this rate is given by

$$\rho_\infty\, (\pi R^2)\, u\, (1 + v_\infty{}^2/u^2) \qquad (11)$$

The expression is seen to have a minimum value when the geocentric velocity u equals the sea-level escape velocity v_∞ (= 11·2 km./sec. for the Earth). From the equation of continuity we can also deduce the mean radial velocity near sea-level. It is equal to equation (11) divided by ρ_R. Using equation (9) we obtain

$$v_{\text{rad}} = 1/2\,(u^2 + v_\infty{}^2)^{1/2} \qquad (12)$$

Comparison with Observations

We can use the results of the preceding section to calculate two quantities which can be checked by observations: (1) the absolute value of the rate of accretion by the Earth; (2) the relative counting-rate of a meteor impact detector as a function of distance from the Earth (the absolute rate depends on the sensitivity of a particular detector).

(1) *Accretion.* A normalization must be made to the density of interplanetary dust in the vicinity of the Earth's orbit. Photometric investigations based on measurements of the zodiacal light give values for ρ_∞ which vary in the range of 2×10^{-23} to 5×10^{-21} gm./cm.³ (refs. 10 and 11). Using this range of values in eq. (11), Table 1 is obtained.

Table 1. ACCRETION OF INTERPLANETARY DUST TO THE EARTH (in tons per day)

ρ_∞ (gm./cm.³)	u/v_∞ = 0·1	0·2	0·5	1·0
2×10^{-23}	2,450	1,260	605	485
5×10^{-21}	$6·1 \times 10^5$	$3·1 \times 10^5$	$1·5 \times 10^5$	$1·2 \times 10^5$

An estimate for the minimum value of u/v_∞ can be obtained by assuming the heliocentric orbits of the dust particles to be completely circular and inclined to the ecliptic at an angle of about 2°, a mean value for the nearer planets. The Earth's orbital velocity is 29·8 km./sec., giving a geocentric velocity of the dust particles of more than 1 km./sec. Again, since the eccentricity of the Earth's orbit is 0·0176, the perihelion to aphelion velocity ratio turns out to be $1 + \varepsilon/(1 - \varepsilon)$, or about 3 per cent of the orbital velocity. We can therefore take $u = 1$ km./sec. as a lower limit for the geocentric velocity of interplanetary dust, with most of the dust component responsible for the zodiacal light in the range 1–5 km./sec. ($u/v_\infty \sim$ 0·1–0·5).

It can then be seen from Table 1 that the lower limit of ρ_∞ of about 2×10^{-23} gm./cm.³ gives an accretion-rate in accord with the generally quoted value of about 1,000 tons per day.

(2) *Rate of impact.* Before any comparison is made with observations, it must be realized that it is never the concentration, given by equation (8), which is measured. Generally, an acoustic detector counts the number of particles which impart a momentum greater than some minimum value p_m.

But assuming (1) that detectors have similar values of p_m, and (2) that the momentum of impact is proportional to particle momentum (at least over the range of velocities encountered here), we can calculate the expected counting-rate vs. distance. (Actually, the results are fairly insensitive to assumption (1), see ref. 12.) However, it is quite important to bring in another factor, namely, the velocity of the vehicle on which the detector is mounted.

I have therefore considered three cases[12]: Case 1, stationary observer, that is, a rocket near peak altitude; Case 2, a space probe moving vertically outward with local escape velocity; Case 3, a satellite in circular orbit.

The results for Case 1 are shown in Fig. 1, using a dust particle cloud the particle-radii of which follow the law $f(a)da = a^{-2·8}\,da$. It can be seen that a peak still exists for the rate of impact but at a lower altitude than for concentration. However, the total variation of impact-rate is much greater between infinity and the vicinity of the planet: it increases between a factor of 4 (for u/v_∞ = 0·5) up to a factor 200 (for u/v_∞ = 0·1).

Conclusions

My results predict the existence of a modest dust shell around the Earth, instead of a variation with a factor of 10³–10⁵ increasing uniformly without a maximum[4,6].

Experimental evidence concerning a concentration of interplanetary dust in the vicinity of the Earth is as yet very scanty. The data come from different detectors, different types of vehicles, namely, rockets, satellites, and space probes (corresponding to the three cases mentioned), and were obtained at different times[13]. Discrepancies among individual measurements amount to orders of magnitude at times[14], indicating the possibility of real variations with time, due perhaps to a non-zodiacal dust component.

It appears to be premature, therefore, to draw any firm conclusions from the experimental data at present available about the existence of a dust shell of the type discussed here. Nevertheless, a confirmation of its presence with a maximum as shown, for example by Fig. 1, would be of great importance in establishing the validity of the assumptions underlying the theory of the present work.

I thank M. Dubin, E. J. Öpik and C. W. McCracken for illuminating discussions. This work was supported by a grant of the National Aeronautics and Space Administration, *NsG*-58-60.

NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY OF PROTEINS: THE HYDROGEN BONDING OF WATER IN BOVINE SERUM ALBUMIN SOLUTIONS

By F A. BOVEY

Central Research Laboratories, Minnesota Mining and Manufacturing Co,
St Paul, Minn

THE nature of the 'water of hydration' in aqueous protein solutions has been the subject of much investigation and discussion[1-4], but there is little direct experimental evidence as to whether it exists in a 'frozen' form, comparable with ordinary ice[3], or in some less highly organized state It appeared that measurement of the nuclear magnetic resonance peak positions of water protons in concentrated protein solutions might furnish some information on this point In this communication results are presented for bovine serum albumin solutions at 25° and *p*H 6 8

Arnold and Packard[5] have observed that the chemical shift of the hydroxyl proton signal of ethanol is dependent on temperature, moving upfield by about 1 5 p p m (with respect to the methylene signal) over the temperature range $-117°$ to 78° This was believed to arise from the breaking of hydrogen bonds[6] Similar shifts have been observed on dilution of alcohols[7-9] and phenols[10,11] with non-polar solvents and have been satisfactorily interpreted as due to the dissociation of hydrogen-bonded polymers

Cohen and Reid[7] observed that at 29° the peak position for water dissolved in carbon tetrachloride is at a field 3 68 p p m higher (after bulk magnetic susceptibility correction) than for liquid water Schneider, Bernstein, and Pople[12] found that for water vapour the peak position is 4 58 p p m higher than for liquid water at 0°, susceptibility correction being made Very recently, Tiers and Kowalsky[13] have found that the peak position for liquid water, measured with respect to the methyl group resonance of dissolved sodium 2,2-dimethyl-2-silapentane-5-sulphonate as internal reference (assigned a scale value $\tau' = 10\ 000$), moves to higher field with increasing temperature At 0°, $\tau' = 4\ 983$, at 25°, $\tau' = 5\ 219$ The peak position reported by Cohen and Reid[7] for water in carbon tetrachloride corresponds to 8 93 on the τ' scale The vapour value of Schneider *et al* [12] is approximately 9 56 on the τ' scale, but to be useful this value requires a rather large negative correction for 'solvent shift'[14], which appears to take place for all substances on passing from the vapour to the liquid state, whether hydrogen-bonded or not Since the magnitude of this correction for water is unknown, the value 8 93 τ', based on water in carbon tetrachloride, has been chosen as representing the best approximation to the resonance position of water protons when all hydrogen bonds are broken Assuming, with Pauling[15], that in ice every proton is involved in a hydrogen bond and that in liquid water at 0°, 15 per cent of these bonds are broken, I calculate that for completely hydrogen-bonded liquid water, if it were capable of existence, we would observe the proton resonance at 4 23 τ' We thus have a total difference of chemical shift of 4 70 p p m between hydrogen-bonded and non-hydrogen-bonded protons in water, and since peak positions are reproducible within ± 0 005 p p m in the present work (see below), a change in hydrogen-bonding involving 1 per cent of the water protons should be measurable, while changes involving only a few tenths of 1 per cent should be easily detectable

A 'Varian *V*-4300-2' 40 00-Mc per sec spectrograph was used, together with a 'Varian' variable-temperature probe, sample spinner, audio-oscillator, Hewlett–Packard '522-*B*' frequency counter and 'Varian' recorder Approximately 0 5 ml samples of protein solutions were used, using 5 mm (outside diameter) 'Pyrex' tubes Samples were maintained at 25 0 ± 0 2°, maintenance of a constant temperature is particularly important when external referencing is used, as described later All tubes were evacuated and freed of air by successive freezing and thawing, they were then sealed under 0 5 atmosphere of pre-purified nitrogen

The bovine serum albumin used was purchased from Pentex, Inc (Kankakee, Ill) and was designated 'Lot 9*G*–10', it was found to contain 3 5 per cent moisture Solutions were prepared in deionized water The *p*H of all solutions was found to be 6 80 ± 0 05, no buffers or salts were added

For measurement of water peak positions, internal referencing was first attempted It was found that, measured with respect to sodium 2,2-dimethyl-2-silapentane-5-sulphonate (2 per cent)[13], the water peak of an 11 9 per cent bovine serum albumin solution shifted $-0\ 102$ p p m compared with pure water It was also noted that the reference peak, normally narrow and prominent, became increasingly broad at higher protein concentrations, being barely observable in the 11 9 per cent solution and unobservable in the 23 9 per cent solution This appeared to indicate that the sulphonic acid anion was fairly strongly adsorbed by the protein and was experiencing the latter's much longer correlation time[16] It therefore could not be regarded as sampling all regions of the solution indifferently, as a reliable internal reference should It was found that 1 per cent of 2,2-dimethyl-2-silapropanol-1 (ref 13) showed much less but still perceptible broadening of the methyl peak and gave also a smaller apparent shift, $-\ 0\ 072$, of the water peak in the 11 9 per cent solution *Tert*-butanol (2 per cent), which is much more soluble than the silapropanol, showed no broadening and an apparent shift of water peak of only $-\ 0\ 019$ in 11 9 per cent protein solution To avoid any suspicion of spurious shifts, however, it seemed best to rely chiefly on an external reference For this purpose, hexamethyldisiloxane (obtained from the Dow-Corning Corp) was sealed into 1 mm (internal diameter) capillaries, which were then inserted into the 5 mm nuclear magnetic resonance sample tubes Peak positions were measured by the 'frequency changing' method already described by Tiers[17] At least six measurements were made on each system, values obtained on increasing and decreasing sweeps were averaged to eliminate systematic error from this source. Measurements were found to be reproducible within ± 0.005 p.p.m. average deviation at most, usually the limits were narrower. Only differences in peak positions between water and protein solutions were of interest, and therefore no correction for difference of bulk diamagnetic susceptibility between solvent and reference was necessary.

Solutions of methylamine hydrochloride, potassium acetate, and potassium butyrate were prepared from reagent or C.P. materials and their *p*H values were adjusted to within ± 0.01 unit using a 'Radiometer' *p*H meter. The nuclear magnetic resonance tubes were sealed under purified nitrogen in the same manner as the protein solutions.

Water proton peak positions were measured at 25.0° with respect to hexamethyldisiloxane as external reference for pure water and for solutions containing 0.030, 0.060, 0.119 and 0.239 gm. of bovine serum albumin per c.c. of solution (W_2). There was an appreciable broadening of the signal at higher protein concentrations (up to approximately 5 c.p.s. half-height width at $W_2 = 0.239$), but this did not impair the measurements. The observed differences in peak position are shown in the third column of Table 1, in which $\Delta\delta(\delta_{\text{water, protein sol.}} - \delta_{\text{water}})$ is recorded. Because the diamagnetic susceptibility of the protein solution differs somewhat from that of water, a correction must be made when employing an external reference. The volume susceptibility χ_s of the protein solution can be calculated from

$$\chi_s = W_1\chi_1 + W_2\chi_2$$

where χ_1 and χ_2 are the gram susceptibilities of water and (dissolved) protein, respectively. We have taken χ_1 as -0.721×10^{-6} (ref. 18*a*) and have calculated χ_2 for bovine serum albumin from the Pascal constants and constitutive corrections, as listed by Pople, Bernstein and Schneider[18b]. In column four of Table 1 the calculated values of χ_s are listed. From these the value of the corrected shift of the water peak, $\Delta\delta_{\text{corr}}$ in column 5 is calculated, using the relationship[19]

$$\Delta\delta_{\text{corr}} = \Delta\delta_{\text{obs}} + \frac{2\pi}{3}(\chi_1 - \chi_s)$$

It can be seen that, within experimental error, the differing magnetic susceptibility is entirely responsible for the apparent shift in the water peak of the protein solution.

In the most concentrated bovine serum albumin solution ($W_2 = 0.239$), it can be calculated that the carboxylate group concentration is approximately 0.38 *M*, the ammonium and guanidinium group concentration (not considered separately) approximately 0.32 *M*, and the peptide group concentration approximately 2.2 *M*. Direct measurement at *p*H 6.8 of effect of methylammonium ion (0.5 *M*), acetate and butyrate ion (1 *M*), and *N*-methylacetamide (2.5 *M*), as models for these groups, showed that in the protein solutions they would not affect the position of the water peak within the experimental error of measurement.

It appears that even in very concentrated bovine serum albumin solutions there is no change in the hydrogen-bonding of the water molecules which involves more than 0.1–0.2 per cent of the water protons. By 'change' is meant a disruption of the hydrogen bonds normally existing in water, or the formation of new additional hydrogen bonds (see below) whether with other water molecules or with the protein.

Table 1. OBSERVED AND CORRECTED RELATIVE PROTON PEAK POSITIONS FOR WATER IN SOLUTIONS OF BOVINE SERUM ALBUMIN (BSA), 25.0°

BSA conc., gm./c.c. solution (W_2)	Water conc., gm./c.c. solution (W_1)	$\Delta\delta_{\text{obs}}$	$-\chi_s \times 10^6$	$\Delta\delta_{\text{corr}}$
0	1.000	0	0.721 ($=\chi_1$)	—
0.030	0.978	−0.006	0.724	+0.002
0.060	0.955	−0.008	0.727	+0.006
0.119	0.912	−0.031	0.733	−0.004
0.239	0.821	−0.060	0.746	−0.006

Let us first suppose (somewhat naively) that protein molecules, on being introduced into water, have no effect on the structure of the water other than to interrupt it at the protein–water interface. Taking the bovine serum albumin molecule as a cylinder 145 Å in length and about 30 Å in mean diameter[20], it can be estimated that about each there will be a monolayer containing at least 1,000 water molecules, corresponding to about 28 per cent 'hydration'. Assume that each interfacial water molecule suffers the breakage of one hydrogen bond. In a solution for which $W_2 = 0.24$ and $W_1 = 0.82$ (Table 1), it is readily calculated, assuming a molecular weight of 65,000 for the protein, that about 5 per cent of the total hydrogen bonds of the water would be broken. This should produce a $\Delta\delta$ of $+0.235$, exceeding the experimental error by fifty-fold. It seems, then, that the interruption of the water structure must be compensated by the formation of other hydrogen bonds, either to the peptide linkages or other polar groups of the protein, or in some other way. We have seen that the interaction of water molecules with carboxylate, amino, and peptide linkages in the concentration present in such a protein solution has an essentially negligible effect on the water resonance position, so that the replacement of water–water hydrogen bonds by bonds to these groups is not directly seen as such.

In addition to forming hydrogen bonds with the protein, the interfacial water molecules may become re-arranged in such a way as to form bonds among themselves to the same degree as in water alone, despite the interrupting interfaces. It has been recognized for some time[21] that when hydrocarbons are dissolved in water the heat effect is often slightly negative but that there is a large decrease in entropy, indicating a clustering of water molecules about the intruding hydrocarbon but no breakage of hydrogen bonds. These observations have been recently reviewed and their significance for protein structure pointed out by Kauzmann[4]. It is not unreasonable to suppose that a similar clustering of water molecules occurs about the hydrophobic portions of dissolved proteins (at least 40 per cent of the amino-acid residues of bovine serum albumin can be regarded as hydrophobic), the present results appear to be consistent with this supposition.

Kauzmann has pointed out[4] that the 'icebergs' presumed to form about hydrophobic areas of the protein should not be identified with the 'frozen water' which has been thought by several authors to exist around proteins, and to which a very important part in protein structure and function has been assigned by Klotz[3]. The hydrophobic icebergs have in fact a relatively low thermodynamic stability and would tend to lead to aggregation and insolubility. The nature of this 'ordered' or 'frozen' water, which presumably constitutes the major share of the water of hydration, is still in doubt. The evidence presented here indicates that this ordered water cannot be regarded as having a structure like that of ice (a conclusion also indicated by other lines of evidence) If we suppose that the water of hydration (taken as 0 28 gm per gm protein) has an ice-like structure and that its protons exchange rapidly with the surrounding water, I expect that in the bovine serum albumin solution in which $W_2 = 0\ 24$, a $\Delta\delta$ of approximately $-$ 0 067 would be observed, compared with pure water, which again is well outside my experimental precision It is possible, of course, that there is a disruption of water hydrogen bonds near hydrophobic areas of the protein, and that this is just compensated by more extensive bonding in the 'ordered' or 'frozen' portions of the hydrate water But it appears more logical at present to regard the present results as supporting Kauzmann's conclusions concerning the nature of the water in the hydrophobic areas, and to regard the remainder of the hydrate water as having a degree of hydrogen bonding equal to that of pure water

PURIFICATION OF URINARY CONJUGATED ŒSTROGENS BY GEL FILTRATION

By C. G BELING

Department of Women's Diseases, Karolinska Sjukhuset, Stockholm, 60

A GEL filtration method for de-salting and group-separation of water-soluble substances has recently been worked out by Porath and Flodin[1] This method is based on a column procedure similar to chromatography in which the stationary phase is comprised of a new type of gel ('Sephadex', manufactured by Pharmacia, Ltd, Sweden) The present report suggests that this technique might be of use for the purification and group-separation of conjugated œstrogens in pregnancy urine It might also form the basis of a simple assay method for determination of œstrogens in pregnancy urine

In the early experiments a solution of 5 μgm of sodium œstriol glucusiduronate (Sigma, Ltd, U S A) and/or sodium œstrone sulphate (Schering, Ltd, Germany) in 1 ml of 0 15 *M* acetate buffer (*p*H 7 0) was applied directly to a 1 × 50 cm. 'Sephadex' (*G*25) column As soon as this solution was percolated into the gel, elution was performed with distilled water One-ml. fractions of the effluent were collected and, after evaporation of the tubes. the amount of œstrogen present in each fraction was measured by a modified Kober reaction[2] In these experiments the two conjugated œstrogens were eluted in one distinct peak, which was invariably found in fractions 40–43 Other conjugated œstrogens, such as the sodium salts of 17β-œstradiol-17-glucusiduronate, 17β-œstradiol-3-sulphate, 17β-œstradiol-17-sulphate, œstriol-3-sulphate, 17β-œstradiol-3-phosphate and 17β-œstradiol-17-phosphate, were also eluted in fractions 40–43

In the next series of experiments the conjugated œstrogens listed above were added to male urine which was then percolated through the 'Sephadex' column Usually a concentration of 2–5 μgm. of conjugated œstrogen per ml of urine was used 1–20 ml of these urine samples were applied to the columns without previous purification As soon as the urine was completely percolated into the bed material, elution was performed with distilled water and 1-ml fractions of the effluent were collected Since the main part of urinary pigments was eluted in fractions 22–36, it was not possible to apply a direct Kober reaction to these tubes Therefore the individual fractions were incubated with an extract of the digestive tract of the snail (*Helix*

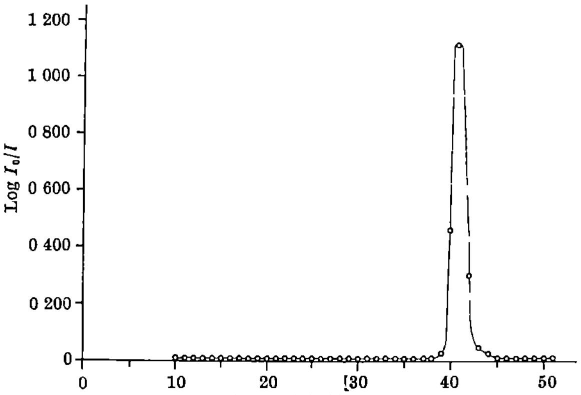

Fig 1 Elution curve obtained by gel filtration of 2 ml of male urine containing 10 μgm of sodium œstriol glucusiduronate 'Sephadex' (*G*25) column 1×50 cm, eluant distilled water, running time 4 hr

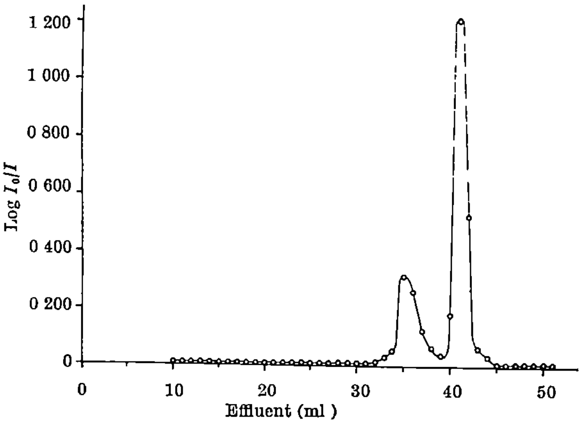

Fig. 2. Elution curve obtained by gel filtration of 1 ml. of pregnancy urine; experimental conditions as in Fig. 1

pomatia, purchased from L'Industrie Biologique Française) and, following enzyme hydrolysis, each fraction was extracted with ether. The ether was evaporated and the amount of œstrogen liberated was measured by the Kober reaction. Under these experimental conditions all the conjugated œstrogens already mentioned added to male urine were eluted in one single zone (fractions 40–43) as shown in Fig. 1.

Approximately 90 per cent of the conjugated œstrogens added to male urine could be recovered within this zone. Also in those experiments where as much as 20 ml. of the urine samples were applied to the columns, all the Kober-positive material was found to be concentrated to fractions 40–43.

On the other hand, when late-pregnancy urine was processed under the same conditions, two distinct peaks were found, one in fractions 33–36 and the other in fractions 40–43 (Fig. 2).

As judged from the elution curve, the second peak of pregnancy urine corresponds to the single peak (Fig. 1) obtained from male urine containing one or more of the reference compounds already named of conjugated œstrogens. It was also found that the addition of small amounts of œstriol glucusiduronate and œstriol sulphate to late pregnancy urine (5–10 µgm. per ml.) resulted in a definite enlargement of the second peak of the elution curve. About 90 per cent of the Kober-positive material present in the two peaks obtained from pregnancy urine was characterized by the Brown method as œstriol. The predominant conjugate of the second peak was found to be identical with œstriol-16 (17 ?)-glucusiduronate. In preliminary work on the conjugated œstrogen present in the first peak, one main compound was found. This appears to be a form hitherto unknown of conjugated œstriol. In paper-partition chromatography or in countercurrent distribution work this compound was found to be more polar than œstriol glucusiduronate.

The gel-filtration technique seems to be most useful for group-separation and purification of conjugated œstrogens in pregnancy urine. Since the recovery from the columns is almost quantitative, the gel filtration seems to be suitable for the isolation of unknown conjugated œstrogens.

As judged from the high yield obtained after enzyme hydrolysis of the purified fractions, the enzyme inhibitors usually present in urine specimens seem to be removed to a considerable extent by the column procedure. This fact made it possible to develop a quantitative method for the estimation of œstrogen in pregnancy urine. The method is based upon gel filtration and enzyme hydrolysis of the purified fractions containing the Kober-positive material. An additional advantage of the proposed method is that after the elution with distilled water the gel is completely regenerated. Furthermore, the columns can be used daily for several weeks without repacking. Since one technician can easily carry out up to 100 determinations a week, this method seems to provide a suitable means for serial estimations of urinary œstrogen excretion in normal as well as in pathological forms of pregnancy.

CHROMIUM-51 TAGGING OF THE α-CHAIN OF HUMAN HÆMOGLOBIN

By Prof. AMOZ I. CHERNOFF

Memorial Research Center, University of Tennessee, Knoxville

THE separation of the α- and β-chains of hæmoglobin by elution from 'Amberlite *CG*-50', utilizing a urea gradient at *p*H 1.9, has become an almost routine procedure in the study of the tryptic peptide patterns of hæmoglobin[1]. Work by Pearson[2] and by Ebaugh[3] indicated that $Na_2{}^{51}CrO_4$ preferentially labels the β-chain of human hæmoglobin, and these observations suggested to me a method for determining the degree of cross contamination of one chain by the other when separated on 'Amberlite' columns. Under the conditions of my experiments, however, tagging of the hæmoglobins by chromium-51 was almost exclusively limited to the α chain of human hæmoglobin *A*.

Hæmoglobin solutions were prepared by standard techniques, following washing of the red cells with normal saline, by lysis with water and toluene. One sample of hæmoglobin was further purified by crystallization from ammonium sulphate solutions following Drabkin's method[4]. Globin preparation was carried out by the technique of Anson and Mirsky[5]. 'Radiochromate' (Abbott) of high specific activity (0.547 mc. chromium-51/ml., 0.00118 mgm. chromium/ml.) was utilized to tag the various hæmoglobin or globin preparations by any one of several methods. Globin (1 gm./100 ml.) was dissolved in 11.7 per cent formic acid, *p*H 1.4, and approximately 80 µc. of chromium-51 added. Following incubation for 90 min. at 32°, the solution was dialysed against water at 4° until no further chromium-51 was lost. The preparation was found to have bound 13 µc. chromium-51/gm. of globin or 0.71 × 10^{-4} mole chromium/mole globin. To

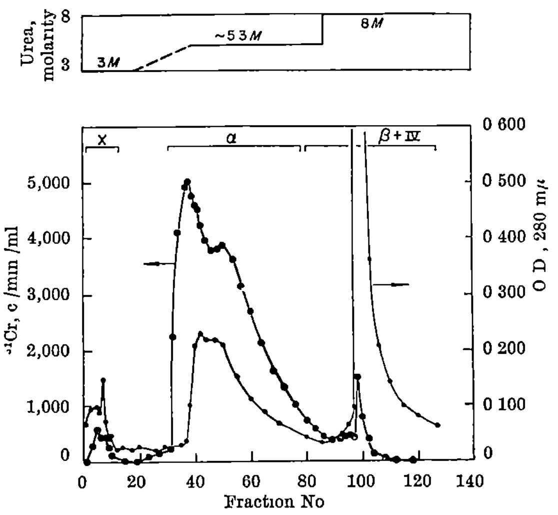

Fig 1 Separation of α- and β-chains of chromium-51 globin-*A* on '*IRC*-50' Interrupted urea gradient, *p*H 1 9

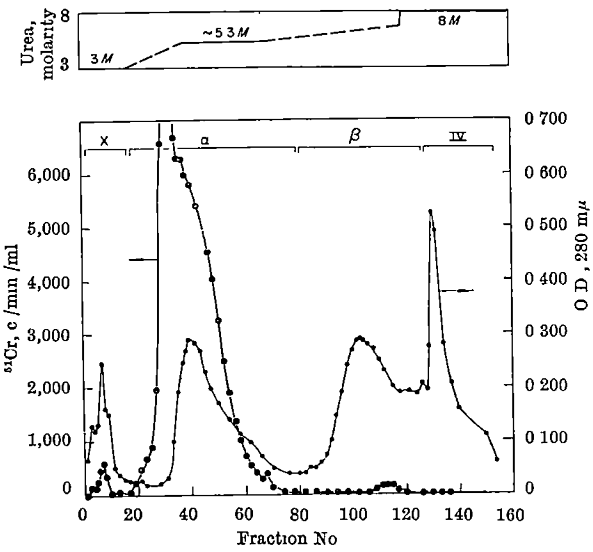

Fig 2 Separation of α- and β chains of chromium-51 on '*IRC*-50' Interrupted urea gradient, *p*H 1 9

hæmoglobin solutions (approximately 1 gm /10 ml) were added the required amounts of dry reagents to constitute a standard acid–citrate–dextrose solution, while purified hæmoglobin powders were dissolved directly into acid–citrate–dextrose solution (approximately 1 gm /10 ml) In each instance, approximately 75 μc of chromium-51 were incubated with the hæmoglobin solution for 90 min at 32°, following which the preparations were dialysed until free of unbound chromium-51 The uptake of chromium-51 was approximately 22 μc chromium-51 per gram of hæmoglobin or 1 1 × 10^{-4} mole chromium/mole hæmoglobin Following chromation of the hæmoglobin, globin was prepared from the tagged material by acid–acetone cleavage

Separation of the α- and β-chains was carried out by my modification of the technique of Wilson and Smith[1] utilizing an interrupted gradient of urea to achieve wider separation of the two chains This technique, described in detail elsewhere[6], uses an initial wash of the column with 3 *M* urea, until the non-protein peak at 280 mμ has been removed (fraction *X*, Figs 1 and 2) The progress of elution is automatically monitored at 280 mμ by a direct recording instrument An increase in the urea gradient is instituted and maintained until the peak of the α-chain has been eluted (approximately 5 2–5 3 *M* urea) at which time the urea concentration is held steady until no further protein can be washed from the column (α fraction, Figs 1 and 2) The gradient may then be resumed and continued until the second major peak (β fraction, Fig 2) is eluted before switching to 8 molar urea (to remove the final pigmented material (fraction IV, Fig 2)) or elution with 8 molar urea may be instituted immediately (Fig 1) Sample counting was done in a well-type scintillation counter on 3-ml aliquots of suitably diluted material, and the results recorded as c p m / ml of solution

The results of two typical experiments are recorded in Figs 1 and 2 The former experiment involved globin prepared from a hæmoglobin solution, the latter, globin prepared from material purified by ammonium sulphate fractionation Except for some non-protein bound chromium-51 which was eluted from the column in the first 300 ml , virtually all the chromium-51 appeared in the α peak Dialysis of this fraction resulted in no loss of chromium-51 activity Tryptic peptide patterns of the material in the β + IV peak of Fig 1 showed very slight contamination of the β-fraction with α-chain peptides, while the α-chain digests were essentially free of any peptides specific for the β-chain No such contamination of the β-chain is suggested in the experiment described in Fig 2 Total recovery of chromium-51 in this experiment amounted to 96 5 per cent of the material applied to the column Calculations of the activities recovered in the various fractions from this run showed 1 75 per cent of the chromium-51 in fraction *X*, 95 8 per cent in the α-fraction, 1 95 per cent in the β-fraction and 0 5 per cent in fraction IV (Table 1) Protein recovery and c p m /mgm of protein are also listed in Table 1

Table 1

Fraction	Protein recovered* (mgm)	Protein recovered (per cent)	Chromium-51 recovered (per cent)	Activity/mgm c p m /mgm
X	0	0	1 75	—
α	290	48 4	95 8	4,290
β	213	35 5	1 95	118
IV	107	17 8	0 5	60
Totals	610	101 7	100 00	

* Protein determinations done by technique of Lowry *et al* (ref 7) Starting material, 600 mgm labelled globin *A*

Although there seems to be little doubt that, under the conditions utilized in these experiments, chromium-51 is bound to the α-chain, the work of Pearson[2] and of Ebaugh[3] suggests preferential binding to the β-chain of human hæmoglobin *A* Pearson showed twice the specific activity in hæmoglobin *H* (β_4) compared with hæmoglobin *A* ($\alpha_2\beta_2$) when the hæmoglobins were tagged with chromium-51 and separated at *p*H 7 0 on starch-block electrophoresis Also, recombination experiments at *p*H 4 7 between chromium-51 tagged hæmoglobin *A* and untagged hæmoglobin *C* yielded no label in the recombined hæmoglobin *C* fraction which, once again, suggested that the chromium-51 was in the β-chain Ebaugh reports experiments utilizing techniques similar to mine for separating the α- and β-chains of hæmoglobin *A* at *p*H 1 9 in which the label was also found in the β-chain, although no peptide analyses were done to prove this association Except for differences in the method of labelling chromium-51, and minor differences in chain separation, the procedures as carried out in our respective laboratories seem comparable Whether minor differences in *p*H, in mole ratios of chromium to hæmoglobin or in incubation time are of primary importance in determining the site of chromium-51 binding remains to be seen It is also possible that conditions exist which permit preferential binding of chromium to either chain of hæmoglobin Work is now in progress to test some of these hypotheses as well as to determine whether chromium-51 binds to a specific site, peptide or amino-acid in the α-chain under the conditions of the experiments reported here

EFFECT OF PROGESTERONE ON PREGNANCY

Method of Administration and Effect of Progesterone

THE conclusion that progesterone is a key hormone in the maintenance of pregnancy in both women and laboratory animals has been challenged It was stressed that the concentration of progesterone in the systemic blood in several species is at its highest value at the onset of labour when myometrial activity and pharmacological reactivity greatly increase, and also that systemic progesterone therapy does not suppress uterine activity in late pregnant women These observations aided the formulation of the theory of local effect of placental progesterone[1–3]

It was proposed by this theory that placental progesterone affects the myometrium directly, that is, before being carried round by the systemic circulation Once in the blood-stream the biological potency of progesterone was assumed to be weakened by its 'binding' to some plasma constituents, which in turn affected its 'transport' to target organs While the local effect of placental progesterone has been demonstrated in a variety of experiments by the functional asymmetry of the uterus, the mechanism by which this effect is enforced remained uncertain

The experiments to be reported here bring the regulation of progesterone effect from the realm of speculation into that of experimentation, by showing the relative ineffectiveness of intravenous progesterone administration, specifically when the hormone is given in a fat emulsion containing lipids

New Zealand white rabbits in our colony with a litter size of more than five usually deliver spontaneously on the thirty-second day of pregnancy However, when induced on the morning of the thirty-first day, by 1 I U oxytocin ('Pitocin') intramuscularly, they promptly deliver their uterine contents[4,5] If induction is carried out on the morning of the thirtieth day, labour is delayed and prolonged in spite of repeated oxytocin treatment, and many placentæ are retained[6] Thus oxytocin induction is only predictable in the 31-day rabbit, and induced labour is so characteristic that it has been used as a measure of oxytocic potency[5,7].

If 12–24 hr before induction on the thirty-first day the animal is treated with 5 mgm progesterone in oil intramuscularly, she does not deliver and remains uninducible so long as progesterone treatment (5 mgm /day in oil, intramuscularly) continues[4,5] If progesterone treatment is given less than 12 hr before induction oxytocin is effective on the thirty-first day[4,5] This and other observations[8] suggest that the progesterone effect has a latency period of 12–24 hr It is of considerable significance to explain this long period of latency and shorten it if possible

We have been supplied with a progesterone preparation which has been dissolved in 'Lipomul', a mixture of fat, lecithin, a polymer, and water This mixture (without progesterone) has been used extensively and in large quantities in human therapy for its high calorie content

We investigated in rabbits the possibility that intravenous 'Lipomul'-progesterone can shorten the latency period of the progesterone effect when used in massive doses Thus 40 mgm progesterone in 10 ml. 'Lipomul' was injected intravenously to pregnant rabbits on the thirty-first day of pregnancy 3 and 6 hr. before induction with oxytocin The animals promptly responded to oxytocin and delivered as characteristic of the normal 31-day pregnant rabbit. Thus these pilot experiments showed that the latency period is not reduced by massive doses of progesterone (~10 times the effective dose of progesterone, in oil. intramuscularly) injected directly into the systemic circulation

These negative results prompted the question whether this type of progesterone treatment is effective 12–24 hr later, for 5 mgm progesterone dissolved in oil and given intramuscularly is effective A group of animals received 40 mgm progesterone in 10 ml 'Lipomul' intravenously on the thirtieth day and induced 24 hr. later on the thirty-first day All animals but one delivered as normal untreated rabbits do The one which failed to deliver on the thirty-first day was successfully induced on the morning of the thirty-second day in spite of the fact that the dose of progesterone was 40 mgm This failure in progesterone therapy was unexpected in a laboratory where pregnancy in rabbits is regularly maintained by 5 mgm (or less) progesterone in oil intramuscularly, not only in this type of experiment, but also in the ovariectomized and placental dislocated animal, or after term in the intact animal We could only account for this failure in progesterone therapy by the route of administration or by the solvent used ('Lipomul')

The difference between the effect of intramuscular and intravenous progesterone was determined by

Table 1

Rabbit No	Litter size	Total weight (gm.)	Induced delivery on day 31	31	32	32	33	Progesterone administration and solvent
*A*46	5	257	5					40 mgm in 'Lipomul' (i v)

*K*10	9	307					9	
*WH*6	9	470			2	7		5 mgm in propylene glycol (i m)
*R*251	6	278			6			8 mgm in 'Lipomul' (i m)
*F*15	5	293			5			10 mgm in 'Lipomul' (i m)
*K*8	10	419					10	40 mgm in 'Lipomul' (i m)

All animals received progesterone treatment on day 30 (except *) and were induced twice a day, starting on the morning of the thirty-first day

**R*243 and *R*215 received progesterone 3 and 6 hr , respectively, before induction on the thirty-first day

intravenous treatment of a group of 30-day pregnant rabbits with 10 mgm progesterone dissolved in oil or in propylene glycol The effect of intramuscular treatment was already known[4,5] The injections were made through a 26-gauge needle which broke up the oil particles into small droplets All these animals delivered a normal litter 24 hr later when induced by oxytocin on the thirty-first day Thus 10 mgm progesterone when administered intravenously is ineffective, whereas 5 mgm intramuscularly is effective

Using another group of 30-day pregnant rabbits the intravenous dose of progesterone was increased to 25 mgm (25 mgm progesterone, dissolved in 0 5 ml oil, was suspended in 1 5 ml propylene glycol) These animals did not deliver on the morning or the night of the thirty-first day, but usually on the thirty-second day Thus 25 mgm progesterone given intravenously is effective although for only a short period Thus about five times more progesterone is needed for the same effect when the treatment is intravenous than when it is intramuscular

If 25 mgm progesterone is effective when administered intravenously and 40 mgm 'Lipomul'-progesterone is not, then 'Lipomul' must oppose the progesterone effect If the dose of progesterone is increased to 100 mgm the intravenous 'Lipomul'-progesterone becomes effective, in spite of the proportional increase of 'Lipomul' from 10 to 25 ml Thus the effect of 'Lipomul', inhibiting the exogenous progesterone action, can be overcome by increasing the dose of progesterone

When only 8–10 mgm 'Lipomul'-progesterone is given intramuscularly it is effective in defending pregnancy in the 31-day rabbit against oxytocin induction

What is of interest in these preliminary experiments is the fact that the progesterone effect is greatly dependent on the route of administration and the solvent used It is known that the *in vitro* effect of progesterone is greatly diminished when the hormone is administered in plasma[9] It is also demonstrated that the local application of progesterone into the uterine horn is very effective and results in a functionally asymmetrical uterus As a result of this asymmetry the animal is capable of delivering the contents of the untreated horn while maintaining pregnancy in the treated horn[10] Recent experiments showed that intramyometrial progesterone treatment is effective in pregnant women (Coutinho *et al*, and Bengtsson, L P , personal communications)

Thus problems of progesterone therapy may be partly overcome by discovering methods of administration which permit the ready transport of systemic progesterone to target organs Such methods may be suggested by experiments on progesterone transport Studies on the superimposed regulation of steroid effects are important, for we may easily overlook the biological significance of a steroid simply because its concentration in the systemic blood does not fit in with our expectations

Effect of a Phospholipid Factor on the Activity of Progesterone

It has been demonstrated that the effect of intravenously administered progesterone is dependent on the solvent used. Pregnancy was prolonged in rabbits by 25 mgm. progesterone in oil–propylene glycol suspension, whereas 40 mgm. progesterone in 'Lipomul' was ineffective (previous communication).

The possibility having been considered that certain compounds in 'Lipomul' counteract the effect of exogenous progesterone in prolonging rabbit pregnancy, it was of interest to determine if 'Lipomul' itself would alter the physiological effect of endogenous progesterone.

New Zealand white rabbits, 21–26 days pregnant, were given 150–200 ml. 'Lipomul' intravenously during a period of 8–12 hr. This treatment resulted in premature labour. Rabbits pre-treated by 5 mgm. of progesterone, intramuscularly, could not be induced by higher doses of 'Lipomul'.

Increasing the amount of 'Lipomul' or the speed of infusion resulted in delivery with dead litter, while further increase led to maternal death in convulsions. Further experiments have shown that the active part of 'Lipomul' is the lecithin fraction. The other components of this emulsion[1] were not effective in producing premature labour.

The lecithin in 'Lipomul' is derived from soya bean phosphatides. It is still obscure whether or not pregnant mammals have phospholipids which could control the effect of progesterone. Work is in progress to purify further the soya bean phosphatides and to isolate from the blood and placenta of pregnant women a fraction with similar characteristics.

This work was supported by grants from the National Institutes of Health (*RG*–7942), the Population Council, and the Sigfrid Jusélius Foundation, to which we wish to express our thanks.

Our thanks are due to Dr. Harold L. Upjohn of the Upjohn Co. for the generous supply of 'Lipomul' (an intravenous fat emulsion) and its components.

A PERCHLORIC ACID–NAPHTHOQUINONE METHOD FOR THE HISTOCHEMICAL LOCALIZATION OF CHOLESTEROL

By DR. C. W. M. ADAMS*

National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Bethesda, Maryland

The histochemical demonstration of cholesterol by adaptations[1] of the Liebermann–Burchard reaction has never been satisfactory owing to diffusion of the coloured product and to destruction of the tissue by the concentrated sulphuric acid used in the method. The bismuth trichloride method[2] for cholesterol appears to be somewhat capricious when used in histochemistry[3]. The method to be described, a perchloric acid–naphthoquinone reaction, is more sensitive and gives better localization of cholesterol than either of the older methods.

Frozen sections from tissues fixed in calcium–formol are mounted on glass slides and dried in air. The reagent is 0·1 per cent 1,2-naphthoquinone-4-sulphonic acid in a mixture of ethanol–perchloric acid (60 per cent)–formaldehyde (40 per cent)–water (2 : 1 : 0·1 : 0·9 v/v). The sections are painted with reagent and heated on the bottom of an oven at 60–65° for 5–10 min. until the red colour which first appears turns dark blue. (Sections left floating in calcium–formol for some days react more briskly and intensely than those freshly cut.) A drop or two of 60 per cent perchloric acid is placed on the section and a coverslip lowered into position. The dark blue colour of cholesterol is stable in perchloric acid for a few hours and then gradually turns greyish black. The colour is not stable in either water or glycerine-jelly.

To test the specificity of the method, 5 mgm. samples of the following compounds were spot-tested on glass slides with the perchloric acid–naphthoquinone reagent.

Lipids: Red turning dark blue: cholesterol (3-hydroxy, Δ^5), cholesterol oleate, cholesterol palmitate, cholesterol stearate, cholesterol chloroformate, 7-dehydrocholesterol (3-hydroxy, $\Delta^{5,7}$). Red turning pale blue: cholesterol acetate. Red: lanosterol (3-hydroxy, Δ^8). Black: α- and β-carotene mixture (15 : 85), crystalline vitamin A. Brown: oleic acid, linoleic acid, stearic acid, triolein, tristearin, ovolecithin, brain cephalin, brain cerebroside. No colour: cholestane, cholestanol (3-hydroxy), cholestanone (3-oxy), cholestenone (3-oxy, Δ^4), sphingomyelin.

Amino-acids: Pale pink turning yellow: tryptophan. Pink turning brown: tryptophan-formaldehyde carboline. No colour: tyrosine, phenylalanine, histidine, proline, hydroxyproline, arginine, cystine, cysteine, methionine, glycine.

Purines and Pyrimidines: No colour: adenine, guanine, xanthine, uracil, cytosine, thymine.

Carbohydrates: Pink turning brown: glucose, galactose, mannose, lactose, sucrose, inulin. No colour: inositol, glucosamine, galactosamine.

Other organic compounds: Dark blue: resorcinol. Yellow: phenol, catechol. Orange: indole. Brown to black tars: pyrrole, furfural. No colour: benzene, hydroquinone, pyridine, pyridoxine.

From these spot tests, it is concluded that 3-hydroxy-Δ^5 (or $\Delta^{5,7}$)-steroids and their esters are the only physiological substances which develop a dark blue colour with the perchloric acid–naphthoquinone reagent. Steroids without either the 3-hydroxyl or Δ^5 groups are unreactive, but a second double bond in ring *B* (for example, Δ^7) does not inhibit the

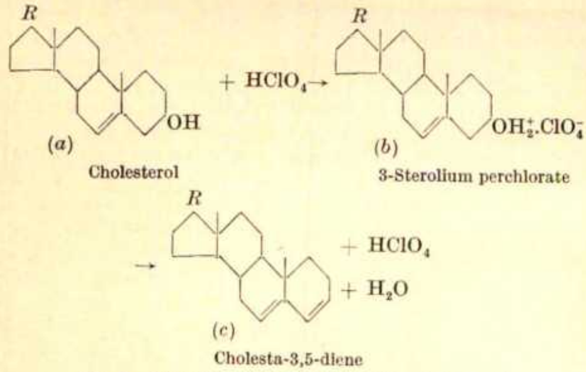

Fig. 1. The action of perchloric acid on cholesterol

reaction. The functional groups of the steroid nucleus demonstrated by this method are therefore essentially the same as those detected by the Liebermann–Burchard reaction[4].

The chemical mechanism of the perchloric acid–naphthoquinone reaction is unknown but previous investigations[5] have shown that perchloric acid has the specific effect, shared only with hexafluorophosphoric acid, of reacting with 3-hydroxy-Δ^5 steroids (Fig. 1*a*) to form insoluble 3-sterolium salts (Fig. 1*b*). The insolubility of these salts may explain the improved localization obtained with this method when compared with the Liebermann–Burchard reaction. By eliminating a molecule of water, excess perchloric acid produces cholesta-3,5-diene (Fig. 1*c*) from the sterolium salt, as does sulphuric acid from cholesterol[6]. Addition of acid to the 3,5-diene may be responsible for the transient red colour which is first formed, but the development of the dark blue colour appears to depend on a reaction between the diene and naphthoquinone. The diene structure is essential, since no colour develops in tissue sections brominated between the perchloric acid and naphthoquinone stages. Although naphthoquinones are dienophiles, Diels–Alder adduction of the diene to the quinone is not a plausible explanation for the reaction, for cholesta-3,5-diene does not undergo diene synthesis at the relatively low temperature used in the test[7]. A related method, using phenol and perchloric and molybdic acids, has been used to identify cholesterol on chromatograms[8]. A diene–quinone reaction may be the basis of both methods, for phenol is probably oxidized by these acids to a benzoquinone.

Fig. 3. Rat sciatic nerve. Staining of myelin sheath but no reaction in axon. (PAN, × *c.* 465)

Fig. 4. Rat adrenal cortex. Intracellular cholesterol in zona fasciculata (*F*) but little staining of reticularis (*R*). (PAN, × *c.* 385)

Fig. 5. Rat aorta. No staining of elastic lamellæ but slight reaction in interlamellar spaces. *I*, intima; *E*, internal elastic lamella; *M*, media. (PAN, × *c.* 136)

Fig. 6. Aorta of 36-year-old man. Faint staining of the reduplicated internal elastic lamella (*E*) and elastic fibres in the adjacent intima (*I*). (PAN, × *c.* 285)

Fig. 7. Aorta of 58-year-old man. Accumulation of cholesterol in intima (*I*) and around internal elastic lamella (*E*). (PAN, × *c.* 95)

The specificity of the perchloric acid–naphthoquinone method for cholesterol was confirmed histochemically by the substantial reduction in colour after the tissue sections had been extracted in acetone at 4° for 18 hr. The success of extraction by acetone, in which cholesterol is highly soluble, indicates that the reaction in tissues is due to lipid. The slight residual staining after extraction may be due to the difficulty of removing all lipid from tissue sections[9] or to the binding of lipid to protein.

In rat tissues, a dark blue colour reaction is seen in the myelin sheaths of the central (Fig. 2) and peripheral (Fig. 3) nervous systems, in the zona fasciculata (Fig. 4) and glomerulosa of the adrenal cortex, in the interstitial cells of the testis and in the lutein cells of the corpus luteum. Slight staining is seen in neuroglial fibres but axons are unstained, as are the unmyelinated axons of the leg nerve of the lobster.

Elastic lamellæ in the normal human and rat aorta are unstained, even though these lamellæ contain lipid[10], including phospholipid[11]. Only traces of cholesterol are present in the interlamellar spaces of the media of the human and rat aorta (Fig. 5), but a strong reaction is given by the lipid-laden macrophages which are frequently found in the more superficial parts of the human arterial intima. The junctional zone between media and intima, the point where phospholipid first accumulates in the early lipoidal lesions of human atherosclerosis[12], contains relatively little cholesterol but the internal elastic lamella itself is sometimes faintly stained at this stage (Fig. 6). The lipid masses of the mature atherosclerotic plaque contain abundant cholesterol (Fig. 7).

A pale pink reaction is seen in the zymogen granules of the rat pancreas and submandibular gland and a weaker background colour of the same hue is seen in many tissues. It is concluded from the spot-tests that the pink colour in tissues is due to tryptophan and possibly carbohydrate, whereas the well-localized dark blue colour obtained with the perchloric acid–naphthoquinone method is a highly specific histochemical test for cholesterol and related steroids.

PROTEOLYSIS OF THYROGLOBULIN BY THYROID ENZYMES

By Dr. MARY T. McQUILLAN, J. D. MATHEWS and Prof. V. M. TRIKOJUS

Russell Grimwade School of Biochemistry, University of Melbourne

SINCE the thyroid hormone is held by peptide bonds within the molecule of its storage form, thyroglobulin, it is generally accepted that hydrolytic enzymes are concerned with its controlled release into the blood stream. The proteolytic activity of thyroid tissue has been shown to vary with the physiological status of the animal as, for example, that following the administration of thyrotrophin or of anti-thyroid drugs[1]. Thus, the purification and the study of the properties of the enzyme (or enzymes) concerned could afford more exact information as to the release mechanism and perhaps help to clarify some types of thyroid disease.

It has been demonstrated that iodinated tyrosines and thyronines can be liberated by incubation of thyroid homogenates[2], saline extracts of the gland[3] or by the action of a partially purified thyroid proteinase on thyroglobulin[4]. The enzyme preparation used by the last-named workers contained peptidase activity. Further purification studies[5] led to the separation of a peptidase fraction ('APATase'), which readily hydrolyses preferentially the pepsin substrate, acetyl-L-phenylalanyl-L-tyrosine[6] (APAT), and a proteinase of high specific activity. The proteinase still retained, however, some activity towards the peptide, L-cysteinyl-L-tyrosine, also a substrate for pepsin[7]. This property has been shown to be due to the presence of another peptidase ('cysteinyltyrosinase') which can be separated from the proteinase[8]. The actions of proteinase and APATase are not influenced by the usual enzyme activators, whereas cysteinyltyrosinase is metal-dependent[8].

The *p*H optimum of the proteinase is 3·5 (hæmoglobin substrate), while the two peptidases, APATase and cysteinyltyrosinase, show peaks of activity at *p*H 4·0 and 5·3 respectively. Like pituitary[9] and adrenal[10] acid proteinases, the thyroid enzyme, when freed from the two peptidases already mentioned, appears to have no action against simple peptide substrates.

We have carried out a series of experiments in which thyroid proteinase and APATase have been incubated, under varying conditions, with preparations of rat thyroglobulin labelled *in vivo* with iodine-131.

Thyroglobulin substrates were prepared as follows: eight female rats, average weight about 200 gm., were each injected intraperitoneally with 90–100 μc. carrier-free iodine-131 as iodide. 48 hr. later the animals were killed, the thyroid glands dissected out, pooled, blended by hand in a glass homogenizer with ice-cold isotonic saline (0·6 ml.), insoluble material removed by centrifugation and the supernatant brought to 42 per cent saturation with ammonium sulphate at 25° C. The precipitate, after standing for 2 hr., was separated, washed with 42 per cent ammonium sulphate, dissolved in water (0·6 ml.) and dialysed overnight. A precipitate which separated was discarded and the supernatant adjusted to 0·015 *M* *tris* buffer (*p*H 7·2) and 0·015 *M* ethylenediamine tetraacetic acid (EDTA), dialysed against the same concentrations of buffer and chelating agent (200 ml.) for 30 hr. and then against distilled water for 17 hr. The faintly opalescent salt-free solution was then heated in a sealed tube at 80° C. for 4 min. to reduce the content of endogenous proteinase, as it has been found that thyroglobulin tends to retain this enzyme during salt fractionation[11]. Protein was then precipitated by adding four volumes of acetone below − 5° C., followed by a small drop of saturated sodium chloride. The precipitate was dissolved in water (about 0·7 ml.), dialysed overnight and held in the frozen state until required.

The enzyme samples were prepared from pig thyroid glands, substantially as described[5], but were further processed by two treatments with buffered EDTA (as for thyroglobulin substrate), to reduce the activities of traces of metal-dependent peptidases, followed by prolonged dialysis against distilled water. The proteinase had an activity of 1,200 units/mgm. protein when incubated for 30 min. at 37° C. and *p*H 3·5 with bovine hæmoglobin substrate, followed by spectrophotometric determinations at 280 mμ (compare Anson[12]). This corresponds to a purification factor of about 400, a twenty-fold improvement on the preparation used in our previous work[4]. The peptidase (APATase) contained 8 units/mgm. protein, one unit being defined as that quantity of enzyme which liberates 1·0 μM tyrosine from APAT (5 μM per ml.) in 60 min. at 37° C. and *p*H 4·0. When incubated at a concentration of 1 mgm./ml. with APAT, the proteinase released the merest trace of tyrosine, as determined chromatographically, whereas APATase, under identical conditions but at a concentration of 0·1 mgm./ml., hydrolysed about 25 per cent of the substrate. The sample of APATase was slightly contaminated by proteinase (10 units/mgm. protein).

Action of purified proteinase on thyroglobulin. In our earlier investigations[4] with labelled thyroglobulin and partially purified proteinase, both prepared from pig thyroid, appreciable hydrolysis was observed at *p*H 3·5. However, in the present work, it became clear from the results of preliminary experiments, using rat thyroglobulin, that substantially greater quantities of labelled components were liberated at higher *p*H, even though the proteinase gave a smooth *p*H-activity curve with bovine hæmoglobin substrate, being only one-fifth as active at *p*H 5·2 as at *p*H 3·5.

In the following experiment the nature of the labelled substances released at the higher *p*H was examined. A half of a thyroglobulin solution prepared as above was mixed with an equal volume of 0·1 *M* ammonium acetate buffer *p*H 5·2. Duplicate tubes containing 0·1 ml. thyroglobulin solution and 0·05 ml. proteinase solution (equivalent to 60 units) were incubated for 2 and 16 hr., while water replaced the enzyme in duplicate control tubes for each period

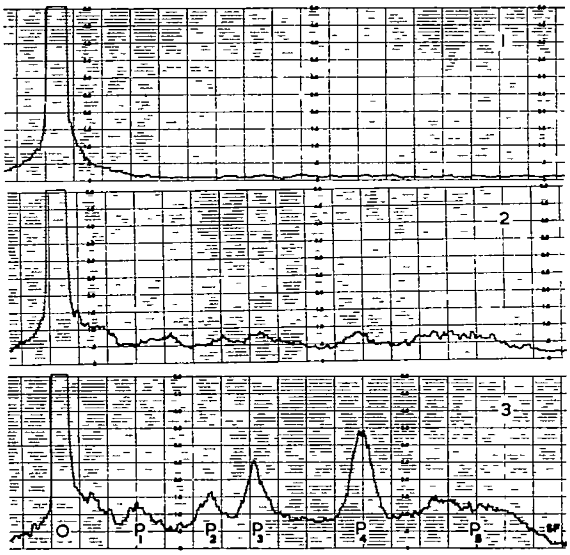

Fig 1 Distribution of iodine-131 on paper chromatograms of thyroglobulin after incubation with thyroid proteinase at 37° C and *p*H 5 2 Chromatograms developed with *n*-pentanol/propionic acid/water (20 3 15) (1) 16-hr control, (2) after 2 hr , and (3) after 16 hr with thyroid proteinase Scannings made with instrument set at full-scale deflexion, 500 c p m , slit width, ⅛ in , scan speed, 3 in /hr , time constant, 40 sec
O = origin, *SF* = solvent front, P_1–P_5 = main areas of radioactivity

A similar set, but buffered at *p*H 3 45 with 0 1 *M* ammonium acetate, was included The tubes were tightly stoppered and shaken during incubation at 37° C Following incubation, 0 025 ml samples from each tube were spotted on to washed Whatman No 3 paper and descending chromatograms developed with *n*-pentanol/propionic acid/water (PPW, 20 3 · 15 by vol) Marker spots contained mono- and di-iodotyrosine and thyroxine (25, 25 and 50 μgm respectively) Duplicate paper sheets (series *B*) were prepared with further 0 025 ml samples from all tubes after these had been standing for 48 hr in the frozen state After cutting the sheets into strips the latter were scanned foi radioactivity using a Nuclear Chicago 'Actigraph II' automatically recording instrument Rapid scans indicated marked increases in the radioactive components released at *p*H 5 2 compared with *p*H 3 45 Accordingly, further examination was restricted to the incubations at the higher *p*H

Fig 1 illustrates the results of slow scanning of the strips corresponding to 2-hr and 16-hr tests and that of a 16-hr control Duplicates corresponded closely. Apart from the origin peak—presumably residual protein—five main areas of activity are discernible (P_1–P_5), each area increasing and becoming more clearly defined with the longer incubation period The control scans showed only background activity except at the origin

Approximate values for percentage hydrolysis were derived from estimates of the areas of migrated radioactivity and those at the origins The results of the calculations are given in Table 1, which lists the duplicate values for the relevant strips from each of the two series of chromatograms (*A* and *B*) run in PPW with 0 025 ml samples On averaging each of the sets of four values, it appears that about three times as much radioactivity had been released after 16 hr as after 2 hr (approximately 27 and 10 per cent respectively) In view of the variations within the calculations, the exact agreement of three of the duplicate percentages must be regarded as fortuitous

In order to identify the peaks of radioactivity, the residual solutions (0 1 ml) from the incubation tubes were precipitated by addition, with warming, of ethanol to 70 per cent concentration, in the presence of carrier mono- and di-iodotyrosine, thyroxine and a sample of purified pig thyroglobulin (0 5 mgm) prepared by the method of Derrien, Michel and Roche[13] After centrifuging, the residues were washed with 0 2 ml 70 per cent ethanol and the combined supernatants evaporated in micro beakers in a desiccator (phosphorus pentoxide) The residues were then spotted on to paper with ethanol/water/conc ammonium hydroxide (7 2 1), the beakers being monitored for completeness of application, and chromatograms developed with PPW. The radioactivity scans were similar to those of the 0 025 ml samples directly applied The peaks corresponding to P_3 and P_4 (Fig 1), which had the same mean R_F values (0 37; 0 59) as marker spots of mono- and di-iodotyrosine respectively, were further characterized by eluting the areas with the alkaline ethanol solvent and then developing chromatograms of the eluate residues in *n*-butanol / 2*N* acetic acid (1 1) Well-defined areas with peaks at R_F 0 43 and 0 54 accounted for nearly all the radioactivity on the individual strips This was checked by radioautography and by subsequent spraying of the strips with ninhydrin to visualize the carrier iodo amino-acids, which demonstrated exact coincidence between radioactive and coloured zones Although eluted and re-run in butanol/acetic acid the peaks P_1 and P_2 (as in Fig 1) could not be characterized although P_2 did have a component at the same R_F as mono-iodotyrosine It is possible that they represented, in part, small peptides The elongated peak (P_5) of R_F 0 70–0 90 suggested a double character on radioautography, the higher part corresponding to marker thyroxine On eluting and re-running in *n*-butanol/*n*-pentanol/2 *N* ammonium hydroxide (BPA, 1 1 2), radioactive peaks were found at R_F values 0 00, 0 08, 0 14 and 0 20, with a broad spread of radioactivity through R_F 0 32 corresponding to thyroxine Thus, P_5 appeared to consist of a mixture, but the evidence strongly suggested thyroxine as one of the components An unequivocal demonstration of the direct release of thyroxine by the proteinase preparation was obtained in the following experiment

An apparent synergistic action of proteinase and APATase on thyroglobulin In the preparation of the

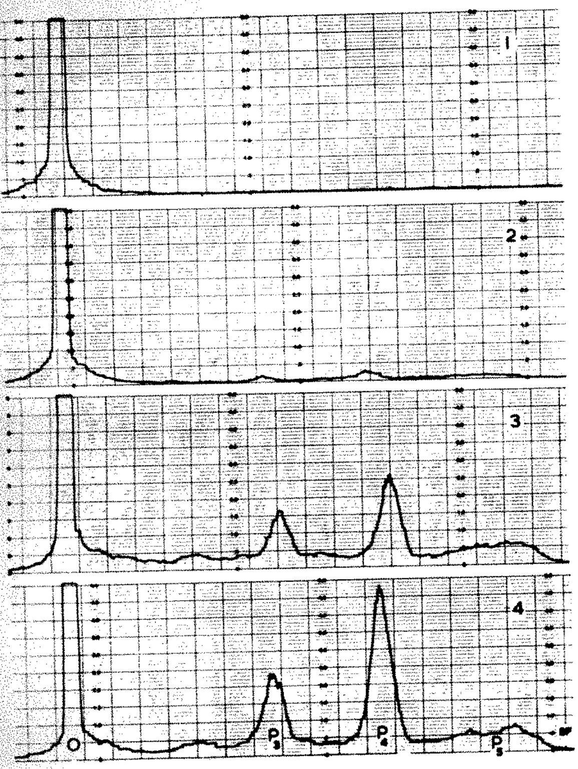

Fig. 2. Distribution of iodine-131 on paper chromatograms of thyroglobulin after incubation with thyroid proteinase and/or APATase at 37° C. and *p*H 5·25. Chromatograms developed with *n*-pentanol/propionic acid/water (20 : 3 : 15). (1) Control; (2) after 16 hr. with APATase; (3) after 16 hr. with proteinase; (4) after 16 hr. with proteinase plus APATase. Scannings made with instrument set at: full-scale deflexion, 1,500 c.p.m.; slit width, ⅛ in.; scan speed, 6 in./hr.; time constant, 20 sec. O = origin; SF = solvent front; P_3–P_5 = main areas of radioactivity

labelled thyroglobulin sample for this experiment the step involving dialysis against buffered EDTA was omitted as the chelating agent was present during incubation. The thyroglobulin solution was adjusted to 0·015 *M* ammonium acetate, *p*H 5·25, and 0·015 *M* EDTA, and 0·1 ml. added to each of eight incubation tubes which were tightly stoppered and pre-incubated for 1 hr. at 37° C. Duplicate tubes then received 0·05 ml. of solutions of (*a*) proteinase (60 units), (*b*) APATase (0·4 unit) and (*c*) proteinase (60 units) plus APATase (0·4 unit), the two control tubes having water only added. After 16 hr. incubation 0·025 ml. samples were applied to paper, run in PPW and the strips scanned as in the previous experiment. The tracings are shown in Fig. 2. Duplicates agreed closely. In the case of the proteinase alone there are again well-marked peaks (P_3, P_4) corresponding to mono- and di-iodotyrosine. Noteworthy is the virtual absence of peaks P_1 and P_2 (compare Fig. 1) and the greater relative concentration of radioactivity in the higher R_F region of P_5 coincident with thyroxine marker. Most striking, however, is the considerable augmentation of radioactivity in the areas corresponding to mono-iodotyrosine and, particularly, di-iodotyrosine, in the tracings of the samples where the two enzymes were associated. APATase alone released very little radioactivity and this could have been due to a trace amount of proteinase in the APATase sample (equivalent to 0·5 proteinase unit in the 0·15 ml. of incubated solution). The contributions of the three main areas, P_3, P_4 and P_5, to the migrated radioactivity, in the case of the proteinase alone and proteinase plus peptidase, as derived from the 0·025 ml. scans, are shown in Table 2.

Table 2. CONTRIBUTIONS OF RADIOACTIVE AREAS, P_3, P_4 AND P_5 (FIG. 2), TO TOTAL MIGRATED RADIOACTIVITY FOLLOWING TREATMENT OF THYROGLOBULIN WITH (*a*) PROTEINASE ALONE AND (*b*) PROTEINASE PLUS APATASE AT *p*H 5·25

Radioactive area	Proteinase (duplicates)		Proteinase + APATase (duplicates)	
P_3	4,900*	5,200	7,400	8,300
P_4	7,900	7,900	15,100	15,700
P_5	6,700	6,600	7,900	8,400
Total migrated	28,100	28,700	39,300	40,900
Total migrated less P_3, P_4, P_5	8,600	9,000	8,900	8,500

* Figures are given as counts per min. of iodine-131 (corrected for decay back to day of injection).

P_3 = mono-iodotyrosine; P_4 = di-iodotyrosine; P_5 = thyroxine-containing area.

The high R_F radioactive areas (P_5) for both proteinase and combined enzymes were unequivocally demonstrated to contain thyroxine as one of the components by further chromatographic examination of the residual solutions (0·1 ml.) from the relevant incubation tubes. Following development in PPW and elution of the areas coincident with marker thyroxine, the duplicate eluates were combined, carrier thyroxine added and the eluate residues then rechromatographed with the solvent system BPA. The 'thyroxine' areas were eluted and the residues re-run in *n*-butanol / 2*N* acetic acid (1 : 1). The chromatograms were checked by radioautography at each stage. Fig. 3 depicts the final tracings, which show in each case a well-defined thyroxine area at R_F 0·72 which coincided exactly with the carrier thyroxine—visualized by ninhydrin—with a minor peak of higher R_F which was not characterized. The total radioactivity in the thyroxine areas was higher when the enzymes were associated but, in view of the involved chromatographic and elution procedure, this difference may not be significant.

It may be concluded from the above results that thyroid acid proteinase is able to degrade thyroglobulin with the release of mono- and di-iodotyrosine and thyroxine. However, it is also possible that even the trace amount of APATase in the purified proteinase sample was the catalyst responsible for the release of the iodo amino-acids from peptides

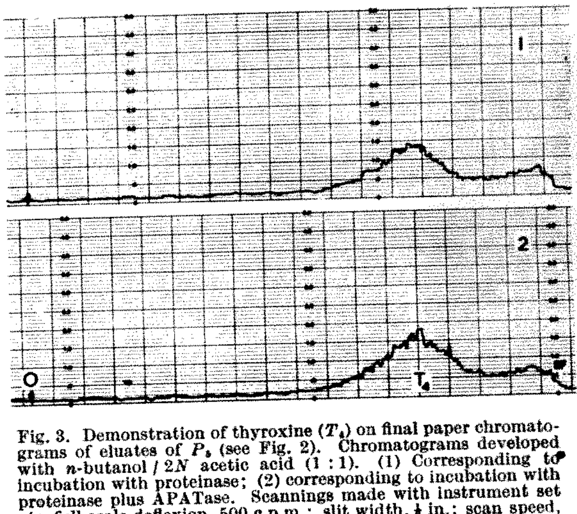

Fig. 3. Demonstration of thyroxine (T_4) on final paper chromatograms of eluates of P_5 (see Fig. 2). Chromatograms developed with *n*-butanol / 2*N* acetic acid (1 : 1). (1) Corresponding to incubation with proteinase; (2) corresponding to incubation with proteinase plus APATase. Scannings made with instrument set at: full-scale deflexion, 500 c.p.m.; slit width, ⅛ in.; scan speed, 3 in./hr.; time constant, 40 sec. O = origin; SF = solvent front; T_4 = thyroxine

produced by the proteinase as intermediates. In any event, as the peptidase had almost negligible action on intact thyroglobulin, it seems clear from the results that the two enzymes can act synergistically in the hydrolysis of the protein. It is not possible at this stage to make a concise evaluation of the respective contributions of the two enzymes, particularly as specific activities were not determined. In this connexion our earlier observation[4] may be recalled that the specific activities of enzymically released mono- and di-iodotyrosine were higher than those of the amino-acids isolated from the same sample of labelled thyroglobulin after complete chemical hydrolysis. This implied, possibly, a 'terminal turnover' in the biosynthesis and degradation of the iodo amino-acids.

Our present investigations are designed to clarify further the nature of the primary actions of thyroid acid proteinase and peptidases.

Mr. R. E. Loughlin was associated in preliminary experiments of this investigation. One of us (J. D. M.) has held the Thomas and Elizabeth Ross Scholarship and we are also indebted to the National Health and Medical Research Council for a grant in aid of this work.

DEMONSTRATION OF INTERACTION PRODUCTS OF ADENINE AND ADENOSINE PHOSPHATES WITH FORMALDEHYDE

By Dr. D. L. WOODHOUSE

Cancer Research Laboratories, Department of Pathology, Medical School, Birmingham 15

RECENTLY, Alderson[1] ascribed a special role to adenylic acid as the mediator of the mutagenic action of formaldehyde on *Drosophila* larvæ, the main postulated agent being an 'adenylate dimer' produced by the interaction of formaldehyde with the amino-group of this purine derivative in the food mixture. The evidence for such interaction products rests mainly on slight alterations in the ultra-violet absorption spectra[2] after incubation of purine bases, nucleotides, etc., with formaldehyde. In view of the scheme suggested by Alderson[1] for the utilization of the postulated metabolite in deoxyribonucleic acid synthesis and its role in mutagenic activity, further demonstration and, if possible, isolation of such reaction products seemed desirable: experiments have been made therefore to see whether they could be resolved from the reaction mixture by chromatography or paper electrophoresis.

In preliminary tests adenine, 2 mgm./ml., was incubated for 18 hr. at 38° C. in presence of 0·1 per cent formaldehyde. After confirming the effect on the maximum of the absorption curve, 20 μgm. samples (10 μl.) were chromatographed by the ascending method using various solvent systems. The positions of the areas containing purine were made visible by the usual method of photographing with ultra-violet light. Using isopropanol / $2N$ hydrochloric acid (65 : 35) evidence of several compounds was obtained, some with greater R_F values and some with less R_F values than adenine (Fig. 1). This is in accordance with the possibility of the formation of monomethylol and dimethylol derivatives, and the 'dimer' (A—CH_2—A) containing the methylene bridge by conjugation of two adenine residues. Formaldehyde may also react with the imino group at the 9 position of the free purine ring. Adenosine, after reaction with formaldehyde, gave evidence of a component moving faster than the adenosine comparison spot in the isopropanol–hydrochloric acid solvent and in methanol / 90 per cent formic acid / water (160 : 30 : 10).

When adenosine-3′-phosphate was examined after formaldehyde treatment, no separation of components was obtained. In all cases clean separation of the products, some of which are relatively unstable, seemed to be disturbed by the long exposure to the solvents, as shown by trailing.

Experiments were made therefore to see whether useful separation could be obtained by treatment with various ion-exchange materials including types of synthetic resins. When solutions of adenosine and formaldehyde-treated adenosine containing 41 μgm./ml. were exposed for 2 hr. to 'Amberlite *IRC* 50 (H)' resin, 0·5 gm.–8 ml., a much higher proportion of the unchanged adenosine was abstracted as shown by the absorption curves in Fig. 2, and by Table 1. Complete separation of the interaction products from the mixture was not achieved, however.

By paper electrophoresis a clear demonstration of reaction products was obtained with formaldehyde-

treated adenine (20 μgm.) or adenosine-3′-phosphate (60 μgm.); 2 m.amp. per 5 cm. strip for 5 hr. in 0·2 *M* acetate–acetic acid buffer, *p*H 4. Adenine–formaldehyde compounds with less mobility than the untreated marker were detected (Fig. 3) while adenosine-3′-phosphate showed a well-separated spot with greater mobility than the unchanged compound. Formaldehyde-treated adenosine solutions did not give good separation. It would appear that the structures of the riboside and any reaction products are too similar to be influenced differentially by the 'transporting charge' but that the phosphate group confers properties allowing the relatively small effect of the formaldehyde group to be utilized in the separation. Resolution was further improved when 0·1 *M* buffer (4 m.amp. per strip) was used for 3–4 hr. (Fig. 4). Similar separation of products from adenosine-5′-phosphate after exposure to formaldehyde is illustrated in Fig. 5, which shows the unchanged ribotide, and one (possibly two) compounds with greater mobilities than the 5′-phosphate.

Fig. 5 (bottom). Electrophoresis of adenosine-5′-phosphate (*a*) before; (*b*), after treatment with formaldehyde. Conditions as for Fig. 3

The resolution of the nucleotides allowed a computation of the proportions of the components to be made. First, from the dried papers the areas denoted by the positions of the spots on the photographs were cut out, extracted with 4 ml. 0·1 *N* sulphuric acid and the content estimated by ultra-violet spectrophotometry.

From the figures for adenosine 3′-phosphate electrophoresis strips given in Table 2 it can be calculated that some 77 per cent of the nucleotide deposited on the paper was present as unchanged ribotide. Since it was evident from the absorption curves of the

Extracted from undried paper with 4 ml. 0·1 *N* sulphuric acid.

relevant solutions that during drying the formaldehyde combination was reversed to a considerable extent, extraction from an undried paper was also carried out. In this case it is difficult to be sure that the positions for the separated components are selected accurately since they must be judged by the photograph of a dried paper run in parallel. However, the substance which had a greater mobility than the original ribotide then gave an absorption maximum at 363 mμ compared with 258 mμ for adenylic acid under the same conditions (Table 3).

This work was carried out with the support of the Birmingham Branch of the British Empire Cancer Campaign.

GLUTAMYL PEPTIDASES IN RAT AND GUINEA PIG KIDNEY SLICES

By GEORGE G. GLENNER and JOHN E. FOLK

National Institutes of Health, Bethesda, Maryland

Histochemical Demonstration of γ-Glutamyl Transpeptidase-like Activity

UNTIL now, only the purely hydrolytic character of the amidase group of enzymes has been demonstrated histochemically. Recent reports[1,2] have described methods for the colorimetric estimation in serum and tissues of enzyme-catalysed cleavage of γ-L-glutamyl peptides possibly mediated by γ-glutamyl transpeptidase[3]. In order to localize this enzymic activity to tissue sections at a histological level a potentially chromogenic substrate *N*-(γ-L-glutamyl)-β-naphthylamide was synthesized for use in a simultaneous azo-coupling reaction.

The synthesis of *N*-(α-benzyl-N^{α}-carbobenzoxy-γ-L-glutamyl)β-naphthylamide was performed from N^{α}-carbobenzoxy-1-glutamyl α-benzyl ester[4] and β-naphthylamine using the mixed anhydride technique with isobutyl chlorocarbonate in dioxane. The product was crystallized from ethyl acetate–petroleum ether, and had a melting point of 142–44° C. *N*-(γ-L-glutamyl)β-naphthylamide was obtained by catalytic hydrogenation in the presence of palladium black in 80 per cent acetic acid as solvent. The product was crystallized from dilute acetic acid ; its melting point was 228° C. (Analysis found : C, 66·4 ; H, 5·9 ; N, 10·2 ; carboxyl-N, 4·9 (ref. 5). Calc. for $C_{15}H_{16}O_3N_2$: C, 66·2 ; H, 5·9 ; N, 10·3 ; carboxyl-N, 5·1). $[\alpha]^{20}_{D} + 2{\cdot}0°$ (*c*, 1·2 in dimethylformamide made 2 *N* with concentrated hydrochloric acid).

Kinetics of the release of naphthylamine from *N*-(γ-L-glutamyl)β-naphthylamide in a biochemical system using previously reported methods were investigated with rat kidney homogenates. The substrate, which was dissolved in 0·1 *N* sodium hydroxide and then neutralized, was used at a concentration of 0·001 *M* in 0·1 *M* *tris*(hydroxyamino)methane buffer at *p*H 8·5 with 0·0164 mgm. wet weight kidney/ml. No spontaneous hydrolysis of the substrate was noted. Pronounced activation by 0·003 *M* glycylglycine was noted with inhibition by γ-L-glutamyl-L-alanine but no inhibition by α-L-glutamyl-L-valine. There was complete inhibition by disodium phenoltetrabromophthalein sulphonate ('Bromsulphalein')[1]. It was of interest that release of naphthylamine from the naphthylamide substrate was enzymically catalysed many times faster than release of aniline from an analogous DL-anilide compound previously reported[1].

Histochemical work on the characteristics of enzymic release of naphthylamine from *N*-(γ-L-glutamyl)β-naphthylamide was performed predominantly on slide-mounted freshly frozen 10μ sections of guinea pig kidney using an incubating solution consisting of 0·5 ml. of a 4 mgm./ml. (0·013 *M*) stock suspension of substrate in acetone, 0·5 ml. of a 20 mgm./ml. (0·150 *M*) aqueous solution of glycylglycine in 10 ml. of 0·1 *M* *p*H 7·2 *tris* buffer, 28 ml. of water and 1 ml. of a solution containing 15 mgm. of the stable diazonium salt of *o*-aminoazotoluene (fast garnet *GBC*) at 37° C. for 20 min. A sub-optimal *p*H for transpeptidation[3] was used to facilitate simultaneous azo-coupling of the naphthylamine enzymically released. No effect on enzymic hydrolysis was noted after the addition to the incubating medium of 0·01 *M* L-glutamine, 0·01 *M* α-L-glutamyl-L-asparagine, 0·001 *M* magnesium chloride, 0·005 *M* *p*-chloromecuribenzoate, 0·001 *M* sodium iodoacetate, 0·01 *M* and 0·0005 *M* potassium cyanide, 0·01 *M* disodium ethylenediamine tetraacetic acid, 0·001 *M* sodium pyruvate, 0·0001 *M* di-iso-propylphosphorofluoridate or 0·004 *M* sodium taurocholate. 'Bromsulphalein' (0·0001 *M*) completely inhibited enzymic activity as did 0·005 *M* oxidized glutathione. No evidence of enzyme activation was noted using 0·01 *M* phosphate buffer at *p*H 7·2. When acetone-fixed paraffin embedded or acetone-washed frozen sections were incubated in the presence of glycylglycine as the γ-glutamyl acceptor, an estimated 50 per cent increase of activity was noted over incubation in its absence.

From the above histochemical and biochemical evidence it can be concluded that the enzyme which releases naphthylamine from *N*-(γ-L-glutamyl)-β-naphthylamide cannot be identified with glutaminase I since there was no inhibition by either *p*-chloromercuribenzoate or L-glutamine and phosphate did not activate the system. Moreover, it is unlikely that a sulphydryl-dependent enzyme, such as glutaminase I, would be demonstrated by a simultaneous azo-coupling reaction since the sulphydryl group would either be oxidized by, or coupled to, the diazonium reagent. Aminopeptidases described histochemically do not appear to be implicated since potassium cyanide failed to affect the reaction. In view of the above findings and the fact that enzymic release of naphthylamine is inhibited by oxidized glutathione and 'Bromsulphalein' and activated by glycylglycine[1], it would appear that the enzyme demonstrated has many of the characteristics of γ-glutamyl transpeptidase as defined biochemically[1,3].

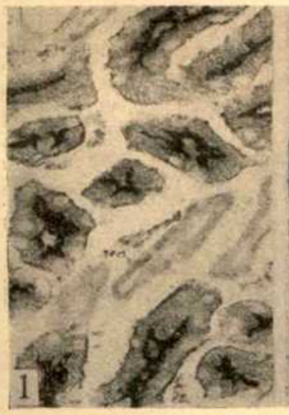

Fig. 1. Enzymic activity in brush border of proximal convoluted tubule

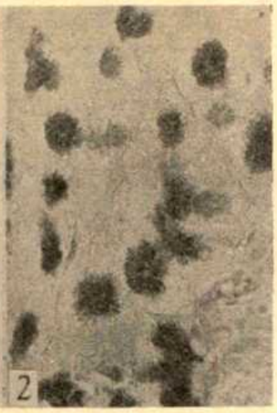

Fig. 2. Enzymic activity in acinar cells of pancreas. No activity evident in islet on the right

With freshly frozen tissues, acetone-washed or acetone-fixed and freeze-substituted paraffin-embedded tissues, γ-glutamyl transpeptidase-like activity was localized in the guinea pig kidney to the brush border of the proximal tubules in the outer medulla and the medullary rays (Fig. 1), and in the pancreas in acinar cells with no reaction evident in islets (Fig. 2). Although transferase reactions have been demonstrated histochemically previously by localizing the synthesized product of the reaction, this report is the first published description of a histochemically demonstrated transferase reaction in which kinetics of the reaction could be investigated during incubation.

Histochemical Characterization of a Unique α-Glutamyl Peptidase Activity

The use of histochemical substrates as a means of localizing known enzymic activities to specific cells or groups of cells in tissue sections has been well established. Histochemical techniques have also been used to distinguish selectively previously undescribed enzymic activity in single cells or groups of cells. The purpose of this communication is to report the identification and characterization of an enzyme(s) which catalyses the hydrolysis of *N*-(α-L-glutamyl)β-naphthylamide in the β-cells of the islets of Langerhans and the interlobular duct epithelium of the guinea pig pancreas.

The intermediate, *N*-(γ-benzyl-N^{α}-carbobenzoxy-α-L-glutamyl)β-naphthylamide, was prepared from *N*-carbobenzoxy-L-glutamyl-γ-benzyl ester[6] and β-naphthylamine using the mixed anhydride technique with isobutyl chlorocarbonate in dioxane. The product was crystallized from ethyl acetate, and had a melting point of 170° C. The substrate, *N*-(α-L-glutamyl)β-naphthylamide, was obtained by catalytic hydrogenation of the carbobenzoxybenzyl ester intermediate in absolute methanol. The substrate was crystallized from 90 per cent methanol-ether and had a melting point of 174–75° C. (Analysis found: C, 62·3; H, 6·2; N, 9·3; weight loss on drying at 100° C. under vacuum, 5·8; amino-N, 4·9 (ref. 7); Calc. for $C_{15}H_{16}O_3N_2.H_2O$; C, 62·1; H, 6·2; N, 9·7; weight loss, 6·2; amino-N, 4·8 $[\alpha]^{20}_{D}$ + 42·5° (*c*, 1·0 in dimethylformamide made 2 *N* with concentrated hydrochloric acid).

Initial investigations using a simultaneous coupling technique revealed localization of enzymic activity in the guinea pig pancreas to the β-cells of the islets of Langerhans (Fig. 3) and the epithelium of the interlobular ducts (Fig. 4). The *p*H optimum with *tris*(hydroxyamino)methane buffer was 6·2. Histochemical work was performed on slide-mounted fresh-frozen 10μ sections of guinea pig pancreas employing an incubating solution containing 0·105 mgm. of substrate and 0·375 mgm. of the stable diazonium salt of *o*-aminoazotoluene (fast garnet salt *GBC*) per ml. of 0·2 *M tris* buffer, *p*H 6·2 for 30 min. at 27° C. Substrate was added as a stock solution (4·2 mgm./ml.) in acetone in order to facilitate its dissolution.

Complete inhibition of enzymic activity was obtained with 0·01 *M* disodium ethylenediamine tetraacetic acid, 0·01 *M* citrate, 0·01 *M* phosphate or 0·001 *M* cadmium chloride, while marked activation of hydrolysis was evident on the addition of 0·001 *M* calcium chloride. The addition of 0·001 *M* potassium cyanide or 0·001 *M* cobaltous chloride resulted in a moderate activation. No significant effect on enzymic activity was evident with 0·001 *M* magnesium or manganous chloride nor with 0·001 *M* iodoacetate, 0·005 *M* *p*-chloromercuribenzoate, 0·001 *M* zinc sulphate, 0·0001 *M* di-iso-propylphosphorofluoridate or 0·001 *M* nickel chloride. The peptide α-L-glutamyl-L-phenylalanine caused pronounced inhibition of activity at 0·01 *M* concentration while no inhibition was observed with the same concentration of L-isoglutamine, L-asparagine, L-leucinamide, benzoyl-DL-arginine amide, L-glutamine, L-glutamic acid or glycylglycine.

From the above histochemical evidence it would appear that the enzyme(s) responsible for the hydrolysis of *N*-(α-L-glutamyl)β-naphthylamide in the β-cells of the islets of Langerhans and the interlobular duct epithelium of the guinea pig pancreas is activated by calcium, and inhibited by disodium ethylenediamine tetraacetic acid; in other words, it is a metal-activated enzyme. The fact that activity is not inhibited by leucinamide and the lack of effect of magnesium on the hydrolysis-rate of the histochemical substrate would tend to exclude the significant participation of the enzyme leucine aminopeptidase[8] in a hydrolytic reaction in the above sites. No other histochemical peptidase substrates including an *N*-(γ-L-glutamyl)β-naphthylamide (see previous communication) have been reported to be hydrolysed by an enzyme(s) having the activity characteristics or localizations of that reported here.

Many new potential peptidase substrates have been synthesized in attempts to characterize further this enzymic activity. Among these are the β-L-aspartyl,

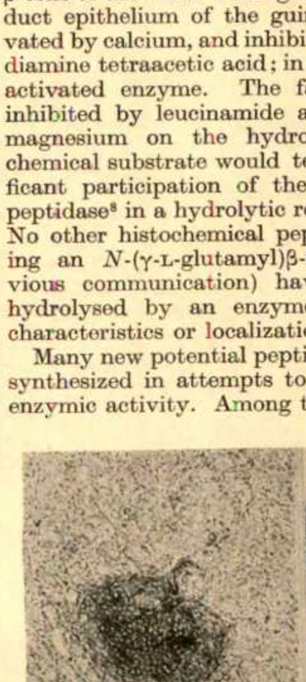

Fig. 3. Enzymic activity in β-cells of guinea pig pancreatic islet.

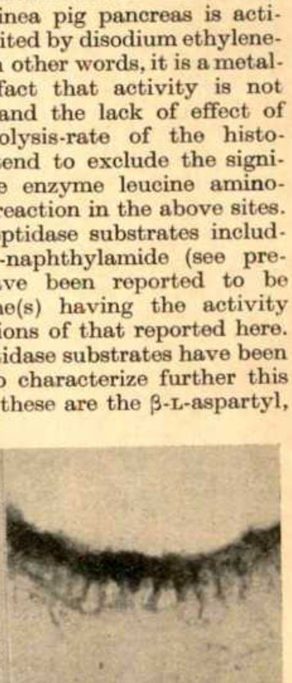

Fig. 4. Enzymic activity in epithelium of interlobular pancreatic duct

α-L-aspartyl, α-L-asparaginyl and α-L-glutaminyl-β-naphthylamides. None of the foregoing compounds was hydrolysed enzymically in the duct epithelium or β-cells of the islets of Langerhans of the guinea pig pancreas.

Attempts to purify the enzyme(s) responsible for the hydrolysis of *N*-(α-L-glutamyl)β-naphthylamide are in progress and a more detailed report of the kinetics and tissue localization of this activity will be the subject of a future communication.

ANTIBIOSIS AMONG LACTOBACILLI

By H. C. DE KLERK and Prof. J. N. COETZEE

Department of Microbiology, University of Pretoria

IN an investigation of lysogenicity in lactobacilli, 199 strains of lactobacilli were examined. One hundred and eighty-nine of these strains were isolated from as many different sources of human saliva, and many have previously been used in attempts to isolate lytic phage[1]. They comprised 140 homofermentative and 49 heterofermentative species. The remaining ten strains are type-cultures kindly supplied by Dr. M. Elizabeth Sharpe, of the National Institute for Research in Dairying, Reading, England. The composition of the tomato dextrose broth and agar used has been mentioned in ref. 1 and all cultures were incubated at 37° C. in an atmosphere of carbon dioxide. Lysogenicity was investigated as follows: supernatants of 10-day-old broth cultures were sterilized by shaking with a 1 per cent volume of chloroform. After all traces of chloroform had been evaporated, drops of these supernatants were spotted on lawns of all remaining strains. Plates were then incubated overnight. The supernatants of twelve cultures produced clear areas of inhibition of growth. On occasions a few colonies composed of resistant variants of the indicator strain were present in the zone of clearing. Sub-cultures of pieces of agar cut from the clear areas never showed growth. The maximum dilution in which supernatants are active is 1 : 10. Afterwards these twelve supernatants were tested against a further 269 homofermentative and 86 heterofermentative salivary strains of lactobacilli. Three of the supernatants, Nos. 253 *A*, 713 *A* and 838 *A*, possess identical spectra of activity. The remainder show very little overlapping and a total of 127 strains of lactobacilli are killed by the twelve supernatants. Results are shown in Table 1. Cultures from which active supernatants are derived are also inhibitory as indicated in Fig. 1.

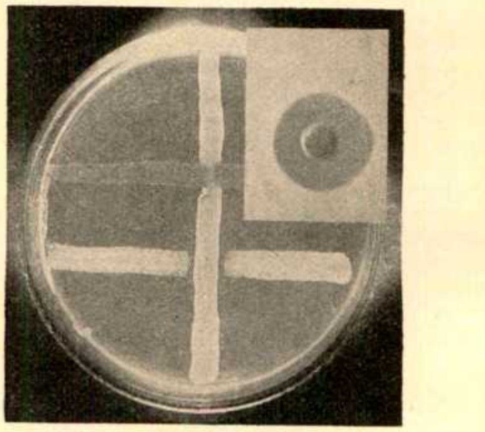

Fig. 1. Fermenti strain 466 washed and streaked on agar. Strain *F* 1 (Reading fermenti) and fermenti 206 cross-streaked. Plates incubated anaerobically overnight. Strain *F* 1 inhibited by strain 466

Inset: 0·2 ml. of a resuspended ammonium sulphate precipitate (*p*H 6·8) of supernatant 466 deposited in sealed hole in agar. After 8 hr. surface covered with sloppy agar containing strain *F* 1 and incubated. Area of inhibition of growth due to diffusion of antibiotic

* No activity demonstrated on 49 strains of *Lactobacillus casei*, 95 strains of *L. casei* var. *rhamnosus*, 13 strains of *L. plantarum* and 16 strains of *L. brevis*.

Figures in brackets indicate number of strains tested.

A, *L. acidophibus*; *B*, *L. bulgaricus* (Reading strain); *S*, *L. salivarius*; *H*, *L. helveticus* (Reading strain); *F*, *L. fermenti*.

The properties of active supernatants differ from those of phage suspensions in that no individual plaques are ever produced, activity is diffusable in agar (Fig. 1) and bactericidal titres are not affected by boiling for 15 min. The *p*H of the supernatants varies between 3·6 and 4·1, but activity is not affected by adjusting to *p*H 7 and/or conducting the tests on agar buffered to *p*H 7 with 1 per cent phosphates. In subsequent work the *p*H of supernatants was adjusted to 6·8. Microscopical observation of sensitive cultures treated with active supernatants demonstrated that the bactericidal action is not due to bacteriolysis and may correspond to the mode of action of colicins Particular attention was paid to avoiding the pitfall of mistaking this inhibition of catalase-negative organisms for the mere action of hydrogen peroxide which may have accumulated in the supernatants Using the methods of Coulthard *et al* [2], the hydrogen peroxide sensitivity of various strains was determined In no case is an inhibitory strain more resistant to hydrogen peroxide than its indicator lactobacilli and it is sometimes more sensitive Activity is not diminished by pre-incubating the supernatants with 0 1 per cent catalase (British Drug Houses) or using indicator strains seeded on agar supplemented with 10 per cent fresh rabbit serum Furthermore, it is possible to increase the titre of supernatants considerably by dialysis against 30 per cent polyethylene glycol Activity is not extractable with ether but is precipitated by saturated ammonium sulphate and also by ethanol The antibiotics often attain maximal bactericidal titres in the supernatants of overnight cultures Titres may decline on further incubation, and the detection of twelve antibiotic-producing cultures with the use of 10-day-old supernatants must be regarded as a minimal finding The antibacterial spectrum of the twelve supernatants (concentrated by ammonium sulphate precipitation) was tested on other members of the family Lactobacteriaceae, various enterobacteria and staphylococci A few strains of *D pneumoniae* and many isolates of enterococci are susceptible to a number of these antibiotics Enterobacteria and staphylococci appear to be immune The action of these antibiotics thus appears restricted to certain members of the family Lactobacteriaceae in much the same way as colicine activity is confined to the family Enterobacteriaceae

Apart from the spectrum of activity, no other differences have been noted between antibiotics derived from the eleven homofermentative strains and the single heterofermentative species Reactions to these antibiotics may serve as a useful complement to phage-typing schemes of lactobacilli[1]

Vincent *et al* [3] have considered the claims of workers who reported antibiotic effects produced by various homofermentative lactobacilli They conclude that the hydrogen peroxide effect can only be excluded in the report of Grossowics *et al* [4] and in their own particular case The antibiotic reported by Grossowics *et al* is produced by an unidentified homofermentative lactobacillus and is soluble in ether It is active on a large series of organisms but no activity against lactobacilli is indicated The antibiotic described by Vincent *et al* is produced by strains of *L acidophilus* It is only produced by aged agar cultures, is inactivated by ethanol and possesses a wide spectrum, including activity on certain *L acidophilus* strains

The antibiotics described here differ in many respects from the two just mentioned How their activity influences the ecology of natural populations of lactobacilli remains to be determined

This work is submitted with the permission of Prof C L de Jager, honorary director of the Nutrition and Dental Health Research Group of the South African Council for Scientific and Industrial Research

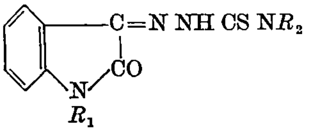
AGENTS WITH HIGH ACTIVITY AGAINST TYPE 2 POLIOVIRUS

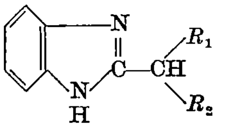
By Dr D G. O'SULLIVAN and Dr P W SADLER

Middlesex Hospital Medical School, London, W.1

ISATIN-β-thiosemicarbazone (I , $R_1 = R_2 =$ H) and some derivatives in which the terminal amino-group remains unsubstituted (that is, I ; $R_2 =$ H) have high selective activity against neurovaccinia[1], alastrim[2], rabbitpox (in tissue culture)[3] and smallpox[4], but show no inhibiting propensities towards ectromelia[5]. When, however, both hydrogen atoms at the end of the side-chain have been replaced by alkyl groups (I, $R_2 =$ alkyl), marked activity against ectromelia is introduced, but the compounds now have no inhibiting action against vaccinia[5] Following these observations on the effect of isatin derivatives on pox viruses containing deoxyribonucleic acid (DNA), assays have been carried out using enteroviruses containing ribonucleic acid (RNA) Here again an interesting difference is observed Most compounds were inactive against type 1 poliovirus, but compounds possessing two substituents on the terminal amino-group (I , $R_2 =$ alkyl) exhibited high activity against type 2 poliovirus



(I)



(II)

Tamm and his co-workers[6] have recently studied and surveyed activities of promising compounds (benzimidazoles and benzotriazoles) towards poliovirus type 2 and have concluded that, although many compounds show purely inhibitory action, only 2-(α-hydroxybenzyl)-benzimidazole (II ; $R_1 =$ Ph, $R_2 =$ OH) and its 5-chloro derivative are potentially useful, in view of their selective action on the virus As 2-hydroxymethylbenzimidazole (II , $R_1 =$ H, $R_2 =$ OH) and the 2-(α-hydroxyethyl)-compound (II; $R_1 =$ Me, $R_2 =$ OH) are both inactive, and as the 2-benzyl derivative shows slight activity, the presence of both the benzyl group and a suitably sited hydroxyl group are probably necessary for useful activity in this particular series

As 1-methyl-4′·4′-dibutylisatin-β-thiosemicarbazone (III) at 30 μM concentration and 2-(α-hydroxybenzyl)-benzimidazole at 100 μM concentration have similar effects on poliovirus type 2 in tissue culture (Fig 1), the structures were examined for comparable features The infra-red spectrum[8] shows the presence of intramolecular hydrogen bonding in the isatin derivative (III), and intramolecular hydrogen bonds are also possible in the benzimidazole (IV)

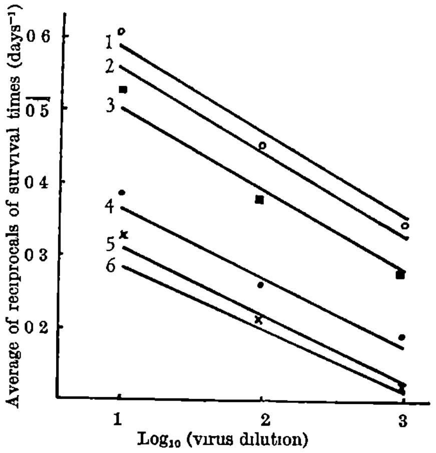


Fig 1 Poliovirus type 2 assays Variation of average reciprocals of survival times (in days) with logarithms of virus dilutions (in presence of 50 per cent of maximum tolerated dose of different compounds) (1) Control line without antiviral compound (2) 2-(*o*-Hydroxyphenyl)-benzimidazole (10 μM) (3) 2-(*p*-Hydroxybenzyl)-benzimidazole (100 μM) (4) 1-Methyl-4′ 4′-dibutylisatin-β-thiosemicarbazone (30 μM) (5) 2-(*o*-Hydroxybenzyl)-benzimidazole (50 μM) (6) 2-(α-Hydroxybenzyl)-benzimidazole (100 μM) For clarity, experimental points have been included only for line 3 (squares), line 4 (dots), line 5 (crosses), and for the control line (circles)

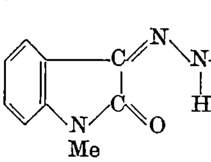
In the latter case, however, this bonding will be weak in view of the strain present in the small ring and in view of the strong tendency of benzimidazole derivatives to form intermolecular hydrogen bonds[9]

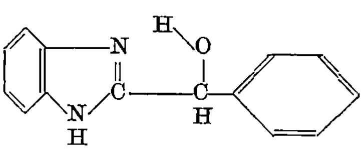
To shed further light on this, some related benzimidazoles were synthesized and tested. 2-(*o*-Hydroxybenzyl)-benzimidazole (V), which possesses the benzyl substituent and a hydroxyl group in the neighbourhood of the nitrogen atom, should form a similar, but slightly stronger, intramolecular hydrogen bond to that in compound (IV) Tissue culture experiments, described later, show that the *o*-hydroxy compound (V) has a similar selective action against poliovirus type 2 to that exerted by the α-hydroxy compound (IV) (see Fig 1)

The hydrogen-bonding hypothesis was further examined by assaying the *p*-hydroxybenzyl- and the *o*-hydroxyphenyl-benzimidazoles (VI) and (VII) respectively

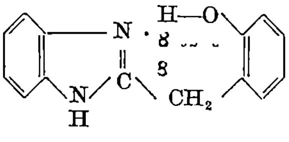
The *p*-hydroxy compound (VI) is incapable of forming any intramolecular hydrogen bonds, but can associate by intermolecular hydrogen bonds Bearing in mind the low activity of 2-benzylbenzimidazole itself, some activity might be expected in the *p*-hydroxy compound, but, if the existence of an intramolecular hydrogen bond is of importance, then the activity should be low Fig 1 shows that the activity of this compound is considerably less than that of the α-hydroxy compound (IV)



(III)

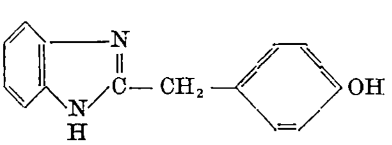


(IV)

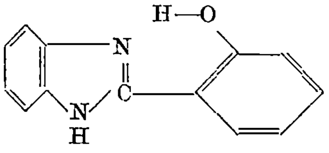


(V)

If the benzyl substituent were important for high activity in this series, then its absence from the *o*-hydroxyphenyl compound (VII) would affect the potential activity This compound can, of course, form intramolecular hydrogen bonds of reasonable strength Fig 1 shows that the activity is less than that of the *p*-hydroxybenzyl compound (VI) This result indicates that replacement of the benzyl group by a phenyl group reduces activity, and, consequently, conjugation between the benzimidazole and benzene rings may be detrimental to the antiviral action



(VI)



(VII)

Eggers and Tamm[10] have shown that the α-hydroxy compound (IV) acts by inhibiting virus multiplication Now the presence of intramolecular hydrogen bonding is a feature common to all antiviral agents of high activity in both the isatin-β-thiosemicarbazone and the benzimidazole series Thus it is probable that an active compound either chelates with a trace metal or forms intermolecular hydrogen bonds with some key molecule involved in the inclusion of nuclear DNA or perinuclear RNA into incomplete virus particles Many simple benzimidazoles[9] and benzotriazoles[11] of lower activity[6] cannot form intramolecular hydrogen bonds, but have been shown by their infra-red spectra to form intermolecular N—H N links Strong, but non-specific, bonding to protein is possible with these compounds

2-(*o*-Hydroxybenzyl)-benzimidazole was prepared by heating under reflux *o*-phenylenediamine (1 mole) and *o*-hydroxyphenylacetic acid (1 mole) with 2 *N* hydrochloric acid (2 moles) for 20 hr The hydrochloride, melting point 130°, crystallized on cooling After dissolving in water and making alkaline, 2-(*o*-hydroxybenzyl)-benzimidazole was obtained which, on crystallizing from aqueous ethanol, had a melting point of 229° (found C, 74 7, H, 5 2, N, 12 1, $C_{14}H_{12}N_2O$ requires C, 75 0, H, 5·4, N, 12 5 per cent)

2-(*p*-Hydroxybenzyl)-benzimidazole was prepared in a similar way using *p*-hydroxyphenylacetic acid After crystallizing from aqueous ethanol, it had a melting point of 270° (found C, 74 8, H, 5 2; N, 12 1 $C_{14}H_{12}N_2O$ requires C, 75 0, H, 5 4, N, 12 5 per cent)

2-(*o*-Hydroxyphenyl)-benzimidazole, melting point 231°, was prepared by the method of Hubner[12], and 2-(α-hydroxybenzyl)-benzimidazole, melting point 201°, as described by Bistzycki and Przeworski[13].

Antiviral assays were determined in tissue culture experiments Monolayers of *ERK* 1 cells[3] were grown in a number of tubes using *ELP* medium[3] After three days, the media were replaced by otherwise identical media, but containing half the maximum tolerated dose of the test compound Test compounds were absent from control tubes Different dilutions (ten-fold) of the virus were added to the tubes, which were then rolled continuously at 37° and examined twice daily for signs of cytopathic effects The end-point was taken when half the cells were affected Average of reciprocals of survival time was plotted against the logarithm of the virus dilution (Fig 1) Relative activities of compounds are given by displacement (to the left) of the line from that for the standard[14]

The results obtained indicate that both 1-methyl-4′ 4′-dibutylisatin-β-thiosemicarbazone (III) and 2-(*o*-hydroxybenzyl)-benzimidazole (V) have activities against poliovirus type 2 which compare favourably with those observed with other compounds and 2-(*o*-hydroxybenzyl)-benzimidazole shows considerable promise as an agent against poliovirus type 2

We thank Dr A P. Goffe, who kindly supplied the viruses (type 1 strain *Sc*, 2 *ab*, type 2 strain *P* 712 *Ch*, 2 *ab*) used in the assays, and Dr F W Sheffield for his generous advice.

RESPONSE OF CATFISH BARBELS TO TASTE STIMULI

By HIDEKI TATEDA*

Department of Biological Sciences, Florida State University, Tallahassee, Florida

TASTE buds were first discovered and their function correctly interpreted by Weber[1] on carp, and it was not until 1867 that Schwalbe[2] and Loven[3] discovered independently similar taste organs on the tongues of mammals Such taste-buds are found over certain areas of the skin of some fish, and are innervated by branches of the facial, glossopharyngeal and vagal nerves (Herrick[4]) In the catfish, these buds are abundant on the barbel, though they are also scattered over the whole body surface Using behavioural techniques, Herrick[4] and Parker[5] studied the effect of applying chemical stimuli to the barbel, and confirmed that these buds are chemosensory organs Later Hoagland[6] attempted to study chemoreception in the catfish electrophysiologically, but although he recorded activity from tactile fibres of the facial nerve innervating the barbel, he could record no spikes from the chemosensory fibres However, he did detect an increase of neural activity through the audio-system This suggests that, with the more refined techniques now available, responses from these fibres might be recorded, and in the present work this was attempted

The freshwater catfish (*Ameiurus melas*) used weighed 200–300 gm The fish was first anæsthetized by dipping into 0 03 per cent tricaine methanesulphonate solution for a few minutes, then transferred into 0 015 per cent tricaine solution and its head stabilized by a holder In order to stimulate the nasal barblet and record electrophysiologically, the dorsal region of the head was exposed to air (Fig 1) Only nasal barblets were used, since no response to chemical stimuli could be elicited from the maxillary barblet After removal of the skin near the basal region of the barblet, the branch of the facial nerve to the barblet was isolated from the surrounding tissue and severed centrally The nerve bundle was usually divided into small bundles, and one of them was placed on platinum electrodes to record the neural response Both nerve and electrodes were covered with mineral oil, and the electrodes connected with an a c pre-amplifier, followed by a cathode-ray oscilloscope and electronic summator to quantify the neural response (Beidler[7]) The stimulating solution was allowed to flow slowly into a special chamber which surrounded the barblet The barblet was washed with water after

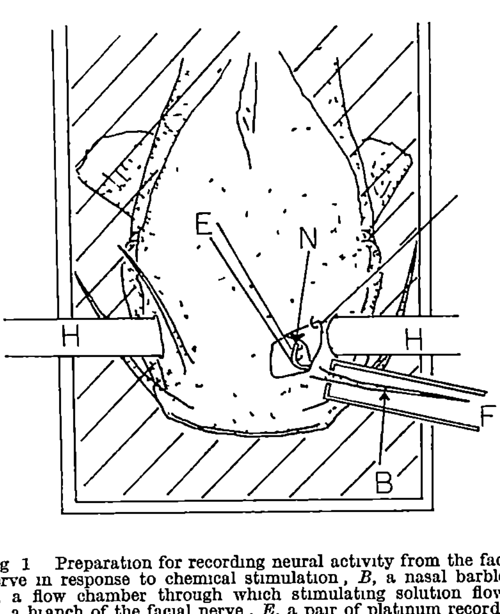

Fig 1 Preparation for recording neural activity from the facial nerve in response to chemical stimulation, *B*, a nasal barblet, *F*, a flow chamber through which stimulating solution flows, *N*, a branch of the facial nerve, *E*, a pair of platinum recording electrodes, *H*, animal holder

each stimulation The responses to adequate concentrations of chemicals were reproducible for several hours, if the blood supply were intact

---

* Present address Department of Biology, Faculty of Science, Kyushu University, Fukuoka, Japan

Hoagland[6] assumed that spikes from the tactile fibres were larger than those from the chemosensory fibres However, the present results show that many spikes caused by rapid flow of solution are of the same order of magnitude as those recorded from chemosensory fibres (Fig 2), although some of them are larger Since the rapid flow of solution causes a short burst of activity of such tactile fibres, only a gentle flow of solution was used

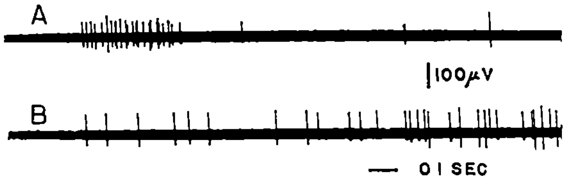

Fig 2 Spikes from the facial nerve, which includes a few intact nerve fibres *A*, responses of tactile fibres to rapid flow of tap water, *B*, responses of chemosensory fibres to 1 *M* sodium chloride The record shown in *B* was obtained after cutting the tactile fibres in the nerve used for record *A*

Application of sodium chloride resulted in a train of spikes which continued throughout stimulation The summated responses to various concentrations of sodium chloride are shown in Fig 3, while in Fig 4*a*, the responses are plotted against concentrations of various salts sodium chloride, potassium chloride, lithium chloride and ammonium chloride The maximum height of the integrated response to each stimulus was used as a measure of the magnitude of response It is interesting to note that potassium chloride is more effective for catfish than is sodium chloride, which agrees with results obtained from carnivores, but is in contrast to those obtained from rodents (Beidler *et al* [8]) The mean value of the ratio

$$\frac{\text{response to 0 25 } M \text{ sodium chloride}}{\text{response to 0 25 } M \text{ potassium chloride}}$$

is 0 36 Thresholds for these salts are about 0 1 *M* (Fig 4*a*) This value is comparable with that of 0 1 *M* obtained behaviourally by Stieck[9] for the minnow and that of about 0 1 *M* obtained by Koketsu and Kimura[10] for the frog, but is higher than that of 0 002 *M* for the rat obtained by Beidler[7] Divalent alkali salts of greater concentration than 0 5 *M* produce an irreversible reduction of activity, but the maximum magnitude of their response is not as large as that to potassium chloride The effect of different anions was tested by using the sodium salts, sodium chloride, sodium bromide, sodium nitrate, sodium sulphate and sodium citrate The magnitude of response to equi-normal concentrations of these salts was almost identical except the response to sodium sulphate, which was smaller than that to the other salts (Fig 4*b*) Application of hydrochloric acid elicited a large initial burst of impulses which declined rapidly until, within 10–20 sec after application, almost no spike activity remained The threshold for hydrochloric acid was about 0 0005–0 001 *M*, which is much higher than that of 0 00001 *M* obtained behaviourally by Allison and Cole[11] for the killifish, but is comparable with that of 0 001 *M* or less for the rat's tongue obtained electrophysiologically by me Hydrochloric acid, 0 01 *M* or higher in concentration, caused an irreversible reduction of response Maximum response to 20m*M* quinine hydrochloride was reached in ten or more seconds after application of the stimulus, and spike activity continued for a short time after washing the barblet with water, although no irreversible change in receptor activity was observed

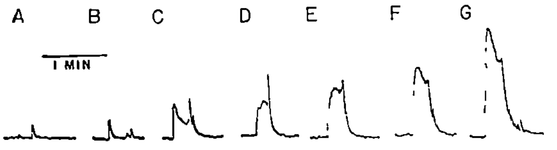

Fig 3 Summated response to tap water (*A*) and to sodium chloride of 0 1 *M* (*B*), 0 2 *M* (*C*), 0 25 *M* (*D*), 0 4 *M* (*E*), 0 5 *M* (*F*) and 1 0 *M* (*G*)

LETTERS TO THE EDITORS

GEOPHYSICS

Diurnal Variation of High-latitude Auroral Frequency on Magnetically Quiet and Disturbed Days

DURING the winters of 1957–58 and 1958–59 an all-sky camera was operated by the Danish Meteorological Institute at Nord in Greenland (geographical co-ordinates 81 6° N, 343 4° E, geomagnetic co-ordinates 80 9° N, 134 5° E)

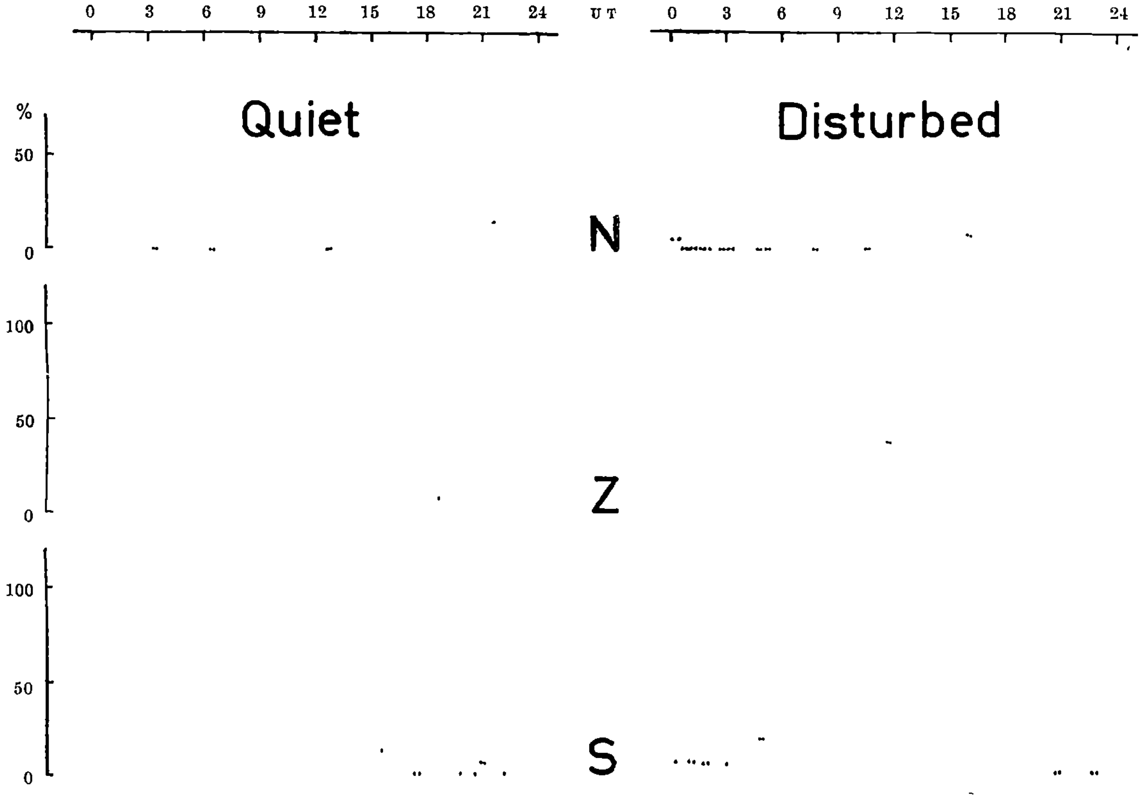

Fig 1 Diurnal variation auroral frequency, Nord, 1957–59

Following a proposal by Stoffregen[1] the sky was divided into sectors north (N), between 80° and 60° northern zenith distance, zenith (Z), between 60° northern and 60° southern zenith distance, and south (S), between 60° and 80° southern zenith distance, north being defined here as the direction perpendicular to the auroral isochasm[2] through the station, geographically this direction is approximately west-north-west

Fig 1 shows the diurnal variation of auroral frequency in the three sectors on international quiet and disturbed days, respectively It is seen that zenithal auroræ are most frequent in the day hours of international quiet days, with two principal maxima at about 5 and 13–14 hr U T On international disturbed days these auroræ are less frequent In S the quiet day variation similarly shows two distinct maxima, at about 6 and 11–12 hr U T, whereas the variation on disturbed days is of a different shape, with a single maximum at about 9 hr U T, that is, near magnetic noon in the Mayaud system[3] Smaller peaks at 9 hr may be seen in the diurnal variation on disturbed days at Z as well as at N

It is proposed that the observation should be interpreted as follows

At magnetic noon the auroral zone is situated not far to the south of the station When on magnetically disturbed days the auroral incidence near the zone increases, the zone broadens and zonal auroræ are observed from the station near magnetic noon

The auroræ which are observed above the station on quiet days become less frequent on disturbed days, possibly due to some sort of modulation effect They may be said to belong to a special polar population (inner auroral zone), or what may be the same in other words, to form a quiet-day appendix to the day-time part of the main auroral zone.

ASTROPHYSICS

Megashatter Cone Hypothesis of the Origin of Lunar Volcanoes

I BELONG to the school that interprets the main observable lunar topographical features as the result of impacts with asteroids and comets. To proponents of this belief, a stunning blow was delivered in 1959 when Kuiper[1] exhibited, during a space symposium in Washington, his beautiful pictures of small features that just could not be impact explosion craters. The discovery of release of carbon dioxide gas also strengthened the picture of some internal lunar feature through which gas could be released.

Now another possibility occurs that the lunar volcanoes are not volcanoes at all, but extremely large shatter cones (which will be referred to as megacones or megamegacones) produced by the shock-waves resulting from impact of an asteroid. These would appear as stumps in the central uplifts of very ancient eroded lunar craters, namely, lunar astroblemes. Dietz[2] has found terrestrial shatter cones as large as 6 ft long in the Kentland, Indiana, 'cryptovolcanic' structure. He proposed the term 'astrobleme' for features of the Kentland type.

It is proposed that megacones of extremely large size exist and that these are composed of the smaller groups of shatter cones discussed in refs. 3 and 4. It is proposed that the roots of a central uplift in a crater formed by a large impact explosion produced by a nickel–iron asteroid consist of a megamegacone in turn composed of many concentrically arranged megacones all originally pointing upwards and inward toward the centre of impact. Most of these will have been almost instantly blown outward leaving a centre region filled with explosion breccia and/or devitrified impact glass. If glass is present, it will undoubtedly contain small spherulites of nickel–iron vapour.

The rebound after impact will lift up this root structure a considerable distance, however, it would always remain below the original lunar surface. Hydrodynamic forces resulting from the melting of the original ground-mass under extreme pressure and plastic flow of breccia dust produced would also tend to force the cone structure upward and outward. This megamegacone structure would then consist of somewhat tilted megacones with vertically up-ended ground-mass and breccia filling the voids between megacones during the original uplift.

After a couple of billion years one would expect that erosion of the uncompressed shattered matter around the stronger megacones would be removed as dust by methods as proposed by Gold[5] for a few craters at least. Shock of later impacts might also tend to unearth the buried compressed megacones by scattering the enclosing dust and exposing the volcano-shaped structure. A crater-like centre might be present in the original megamegacone because of the upward and outward thrust of its megacone components and the shape charge type of ejection of matter from the final rest point of the asteroid. If the volcano-like lunar structures are megacones, then their geometry may be a clue to their mineralogical composition and to the general selenology of the Moon. If the subsurface features of the Moon are largely strained, compressed, cone-like buried structures, then the shallow seismic effects of these regions may be predicted by a study of similar terrestrial features. Sharp, shattered rocks would be expected to be present near megacones because of gradual flaking from the compressed material resulting in the well-known small shatter-cone shapes and dust. The shattered nature of lunar astroblemes would probably promote faster dust formation by action of the extreme variations of temperature during lunar day and night than by the radiation damage mechanism proposed in ref. 5.

Sun–Earth Relations and Associated Periodicities

PERIODICITIES of less than 27 days in geophysical disturbance data have been investigated for many years, with inconclusive results, due to inherent difficulties in determining the statistical significance of the computations. However, there is now an increasing amount of evidence, arising from the examination of independent data samples, to support the existence of such periodicities. Some of the recent evidence is summarized here.

Auto-correlation of the 3-hourly magnetic planetary index a_p, during short moderately disturbed intervals in 1952, disclosed periods of from one to four days[1]. Moreover, the times of occurrence of magnetic impulses seemed to be closely connected with the amplitude of these periodicities, and with changes from one periodicity to another.

Ward[2] computed the variance spectrum of the daily C_i, K_p, and A_p indices for some portions of 1941–56, and found periods of $27/n$ days, with $n = 1, 2, 3, 4, 5$ and 6. No interpretation of the overtones of the 27-day period was given.

An examination has been made of the time separation, ΔT, between 817 magnetic impulses occurring during 1949–59. Intervals of up to 70 days were tabulated. The declining portion of the sunspot cycle, 1949–54, shows maxima in the number of occurrences $N(\Delta T)$ at about the period of solar rotation. Similar maxima do not occur in $N(\Delta T)$ during 1955–59. The same data were examined for higher frequencies, using a one-day running average. During 1949–54, in addition to the solar rotation maxima, other maxima in $N(\Delta T)$ occur at multiples of about $3\frac{1}{2}$ days. Similar maxima during 1955–59 occur at multiples of about 3 days (Fig. 1). This periodicity in $N(\Delta T)$ was

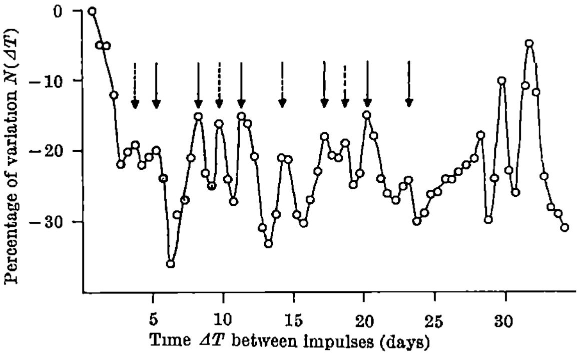

Fig. 1. The time separation ΔT between magnetic impulses, 1955–59

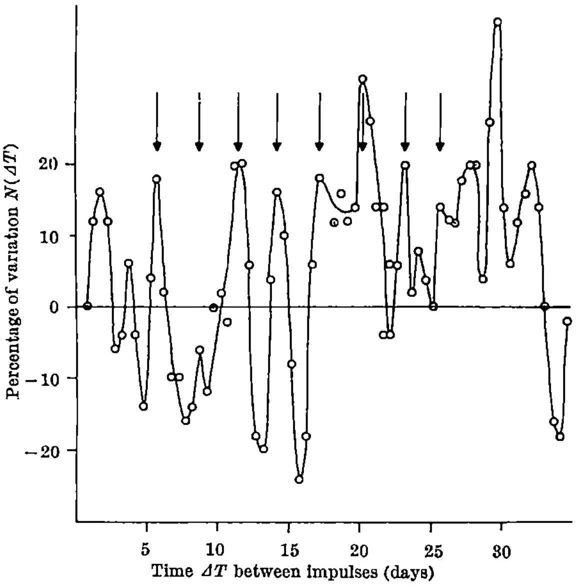

Fig 2 The time separation ΔT between magnetic impulses during the International Geophysical Year

particularly strong during the International Geophysical Year, and the mean period was 2⅞ days (Fig. 2) The data were insufficient to investigate periods of less than one day.

A separate investigation[3] was made of the time separation, Δt, between the occurrence of solar flares and magnetic *SSC* impulses during the International Geophysical Year All flares listed, from 1^{-} to 3^{+}, were given equal weight in the analysis Intervals of up to 14 days were tabulated to the nearest ¼ day, from *SSC* to flare ($-\Delta t$), as well as from flare to *SSC* ($+\Delta t$) The $N(+\Delta t)$ curves show a 1¾-day periodicity which is not present in $N(-\Delta t)$, and which could conceivably arise from the transit time of a disturbance from Sun to Earth Removal of the 1¾-day component leaves a 3-day periodicity in $N(+\Delta t)$ of about the same amplitude as a 2½-day periodicity in $N(-\Delta t)$ It could not be determined from this analysis whether the above difference between 2½ and 3 days is significant A one-day periodicity in the International Geophysical Year flare listings[4] made it impossible to decide whether the $N(\Delta t)$ contain a non-spurious one-day component.

The above periodicities in the time separation between geophysical disturbance data may be significant in the interpretation of statistical examination of upper atmospheric disturbances It was previously suggested[1] that the 1–4-day periodicities in a_p were consistent with repeated Sun–Earth transits of a hydromagnetic wave Although this is still a possibility, it now seems probable that the observed periodicities are more directly related to the timing of solar disturbance events The solar flare to *SSC* time analysis indicates that such solar disturbance events may occur within ¼ day of flare times, and this investigation is continuing

Possible Solar Flare Effects in the *F* Region of the Ionosphere

I HAVE read with interest the recent communication by Knecht and Davies on this subject[1] which reports a series of large solar flares accompanied by marked effects in the *F* region of the ionosphere A particular feature is that the ionospheric effects and the flares are simultaneous only at isolated locations

In this connexion, I should like to direct attention to a communication by Martyn, Munro, Higgs and Williams[2] In that communication a correlation appeared to be established perhaps even more clearly than in the communication by Knecht and Davies. I write, however, not to claim priority of discovery but to report subsequent developments which considerably modified the conclusions in that communication Continuation of that work brought to light two very significant new facts It was found that the ionospheric disturbances occurred much more frequently than solar flares, and, even more important, that they almost always appeared at Canberra and Sydney with an appreciable time difference They were, in fact, travelling disturbances It becomes obvious, therefore, that there is a high probability, at any single point, of a disturbance occurring close to the time of a flare and an even higher one of a coincidence somewhere

When the War began in 1939, much research work, including the above, ceased Moreover, publication of scientific results was also largely inhibited until after the War, and ionospheric literature and history tend to start from that epoch, after a gap of some seven years

These results, therefore, though reported locally to the Radio Research Board, were never published When ionospheric work was resumed at this Laboratory in 1947 attention soon became directed to ionospheric travelling disturbances[3], and it was realized they were the same phenomena observed earlier.

The characteristics of such disturbances have now been very fully investigated here[4], and their manifestations are becoming more familiar in a variety of ionospheric investigations throughout the world, particularly as a result of work done during the International Geophysical Year Their effects on ionosonde records are similar to those shown in Fig 1 of Knecht and Davies's communication and they can also cause changes in frequency of the signals received by an ionospheric path as in their Fig 2

It would seem that since the ionospheric effects of a solar flare are due to ultra-violet radiation they should all be observed simultaneously over the sunlit surface of the Earth

I would urge the authors, in their further work, to give very careful consideration to these aspects For a correlation to have scientific value it must be significant both statistically and physically.

[1] Knecht, R W , and Davies, K , *Nature*, 190, 797 (1961)

[2] Martyn, D F , Munro, G H , Higgs, A J , and Williams, S E , *Nature*, 140, 603 (1937)

[3] Munro, G H , *Nature*, 163, 812 (1949)

[4] Munro, G H , and Heisler, L H , *Austral J Phys* , 9, No. 3, 343 (1956)

Dr. Munro's scepticism regarding our recent suggestion[1] that certain large flares are associated with effects in the *F* region of the ionosphere is understandable As he points out, a solar photon phenomenon of this type would be expected to be evident over the entire sunlit hemisphere and not only at one or two isolated stations However, since the submission of our original communication, our work has revealed several new facts which may help to account for this apparent non-uniformity

First, from further examination of vertical soundings data, it appears that *F* region flare effects sometimes do occur simultaneously at a number of sunlit hemisphere stations The difficulty, of course, is to be able to determine with any degree of certainty whether or not an effect actually occurred in the presence of the normal variability of the *F* region and the flare-associated increase in *D* region absorption which usually is responsible for the loss of several crucial *F* region observations These factors, coupled with the relative infrequency of large flares, are undoubtedly responsible for the fact that the *F* region flare effect phenomenon has been so infrequently recognized in the past

The second new point concerns the height of the *F*2 layer just prior to the beginning of the flare We have found a strong tendency for the *F* region solar flare effect to occur only at those locations where the height of the *F*2 maximum electron density level ($h_{\max}$) at the time of the flare is relatively low (less than about 315 km)

The flare of November 12, 1960, has been chosen to illustrate these points Fifteen-minute values of *F*2 layer penetration frequency (*foF*2) are shown for six sunlit sounding stations in Fig 1 The stations are arranged in order of increasing $h_{\max}$ as determined by the manual 10-point method The time at which the flare begins (1323 U T) is shown by an arrow on the time-scale Considering pre-flare and post-flare trends, it seems clear that a flare-associated increase in penetration frequency, which is related to maximum electron density, occurred at at least four of the stations (San Salvador, Reykjavik, Belvoir and Talara) Flare-associated increases probably did not occur at Huancayo and Concepcion Note that the magnitude of the flare effect discontinuity seems to vary inversely with $h_{\max}$ This is what would be expected on the simple picture where the flare radiations have peak ionization-rates at a level significantly below the *F*2 layer, the rates falling off exponentially with increasing height above this level

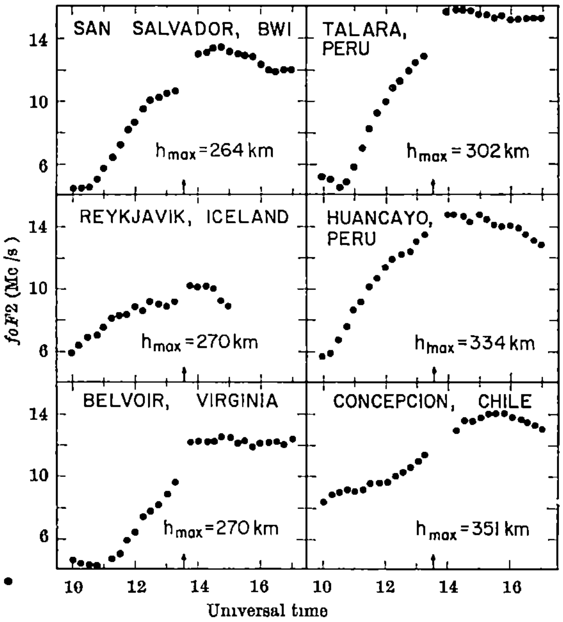

Fig 1 Variations in *F*2 layer penetration frequency at six sunlit sounding stations during the large solar flare of November 12, 1960 Arrow marks flare beginning

Because of the simultaneity of the increases over distances of 10,000 km or more, the possibility that the effects shown in Fig 1 are due to travelling ionosphere disturbances is, it seems to us, extremely remote. Moreover, travelling disturbances can be rather conclusively eliminated as the cause of even some single station occurrences, like that shown in our earlier communication[1] for Adak, Alaska, during the flare of November 15, 1960, since, during the 2½-year period from July 1957 until December 1959, on only one day were occurrences of discontinuities in *foF*2 of this magnitude (1 5 Mc /s increase in 15 min) observed during the corresponding period (1200–1800 L S T) To have one of the largest *F*2 layer travelling disturbances that occur at Adak pass over the station at almost exactly the same time as the occurrence of a large and relatively rare type of solar flare would seem fortuitous indeed Also, according to the earlier work by Munro and Heisler[2], travelling disturbances always take the form of first a reduction in penetration frequency and then an increase whereas in the present phenomena the increase occurs first Lastly, on the ionograms travelling disturbances are generally seen as additional cusps near the penetration frequency Cusps of this type have not been observed on the ionograms following the solar flare events.

Miss R E McDuffie has contributed substantially to the work discussed in this communication.

Interstellar and Interplanetary Communication by Optical Masers

In *Nature* of April 15, 1961, p 205, reference is made to seven stars of nearly the same luminosity and spectral characteristic as our Sun within 10 light years. Apparently this erroneous statement is derived from an earlier general statement in *Nature*, September 19, 1959, p 844, except that 15 light years was changed to 10 light years

Even within 15 light years, there is only one star with "nearly the same luminosity and spectral characteristic as our Sun", namely, the brighter component of the Alpha Centauri system, while possibly one other may be considered to qualify, namely Tau Ceti, with a luminosity of 36 per cent of the Sun and spectral type *G*4 (instead of *G*0 for the Sun)

Peter van de Kamp

Sproul Observatory,
Swarthmore College,
Swarthmore, Pa

Where the stars listed by Cocconi and Morrison are referred to in our article, 10 light years was erroneously written for 15 light years as noted by

Dr van de Kamp Even this is not strictly correct, since one of the distances is as large as 16 5 light years But these differences are not crucial for our purposes

The question whether certain stars are of "nearly the same luminosity and spectral characteristic as our Sun" is a more interesting one A term such as 'nearly' can have no absolute meaning and must depend on a scale of measurement relevant to the discussion at hand For example, it would not seem out of order for an astronomer to refer to stars within 15 light years distance as 'nearby' But such description may be shocking to a pedestrian when he learns that their distance is many trillions of miles In the case of our discussion, nearness or similarity should properly be measured in terms of what might be approximately equivalent for the possible development of life on planets somewhat similar to those we know On such a scale, ranges of about two magnitudes in luminosity and with spectral types *G* and *K*, which cover the stars in question, seem fairly small But it is understandable that Dr van de Kamp, accustomed to contexts where a different scale of measurement may be appropriate, does not find our statement a natural one

We hope that the actual list of stars, to which reference is given, leaves readers in no serious doubt about the facts

PHYSICS

Dependence of Thermo-stimulated Current Curves on Heating Rate

The use of thermo-stimulated current and thermoluminescent ('glow') curves, to determine the energy distribution and population of traps in insulators and semi-conductors, has recently been severely criticized[1] because of the interactions which are now known to occur between energy-levels in the forbidden gap Nevertheless, it has so far been assumed that the shape of such curves is only slightly dependent on the heating-rate in the specimen

During observations of thermo-stimulated currents in a number of cadmium sulphide single crystals following irradiation at 90° K with cobalt-60 γ-rays, we have noted in one specimen a current peak, the shape of which is critically dependent on the rate of temperature increase As shown in Fig 1, the thermo-stimulated current curve generally exhibited two peaks corresponding to trapping-levels at 0 09 eV and 0 13 eV determined using the formula of Grossweiner[2] For rates of rise in temperature between approximately 17° C per min and 19° C per min a very marked increase occurred in the amplitude of the peak corresponding to the deeper trapping-level, the increase appearing as a secondary peak of high resolution No significant changes in the shapes of the two main peaks were observed when the secondary peak was present

If Grossweiner's formula[2] is applied to the secondary peak, the derived energy-level is 1 0 eV, which is below the steady-state Fermi-level calculated from the dark current at room temperature

It seems clear that monomolecular and simple bimolecular models on which theories of 'glow' curves have been based in the past[2-4] do not account for the present observation, but it is reasonable to assume that the high peak is associated with a particular energy-level of traps, which is initially filled and may empty either directly into the conduction band or indirectly through a second energy-level which is initially empty

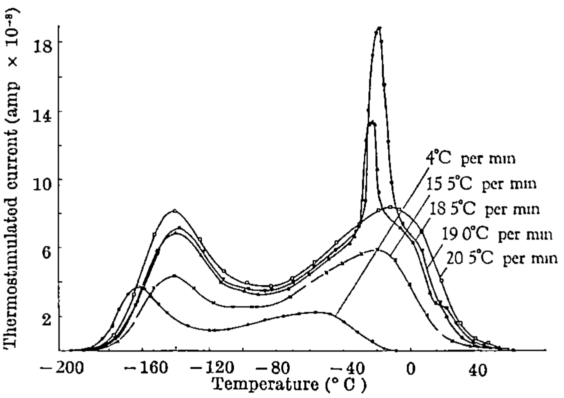

Fig 1 Typical thermo-stimulated current curves for a cadmium sulphide single crystal exhibiting a secondary peak highly sensitive to heating-rate

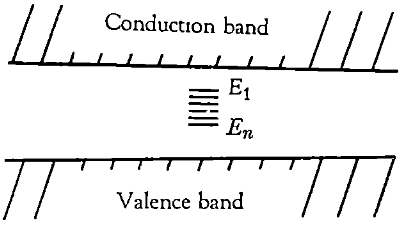

Fig 2

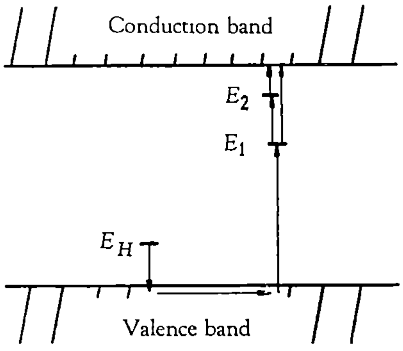

Fig 3

To account for the observation two possible models, shown in Figs 2 and 3, are suggested

In the first model, Fig 2, electrons are assumed to be held in traps of increasing depth E_1 to E_n It is also assumed that the escape frequency factor increases with depth of trap At low heating rates electrons are released directly into the conduction band from E_1 to E_n in turn, giving a broad thermo-stimulated current peak At high heating rates electrons are released from E_n to E_1 in turn, again giving a broad peak For particular values of trap depths and escape frequency factors, a high degree of simultaneous release may occur for a narrow range of intermediate heating rates resulting in a current peak of the type observed

In the second model, Fig 3, electrons associated with the appearance of the anomalous peak are assumed to be held in traps at the level E_1, and may be released either directly into the conduction band or indirectly through the second level E_2 with which E_1 is spatially associated The probabilities of direct or indirect release from E_1 to the conduction band depend on the heating rate and the escape frequency factors for the two levels

If the temperature of the crystal is raised slowly, the peak corresponding to E_1 does not appear since the electrons are all released indirectly through E_2

At some higher rate of rise of temperature the values of the escape frequency factors allow electrons from E_1 to be released directly into the conduction band giving a peak of the type observed

To account for the disappearance of the peak at higher heating rates, a hole trap, E_H, is introduced and E_1 is also assumed to act as a recombination centre

The escape frequency factor for holes in E_H is such that, for heating rates below that corresponding to the appearance of the anomalous peak, the holes are released after the release of the electrons from E_1 At higher heating rates, the holes, which are now released first, recombine with electrons at E_1 so that the anomalous peak no longer occurs.

The accurate evaluation of energy-levels from thermo-stimulated current and 'glow' curves depends on a satisfactory model being available Observations such as the present, and those reported by Hoogenstraaten[1] and by Halperin and Braner[4], indicate the limitations of the method and the care which must be exercised in the interpretation of results

Electrical Conductivity of Calcium Oxide at High Electric Fields

Interest in the study of the electrical properties of the alkaline earth oxides as an aid to understanding the physics of the oxide-coated cathode has led to an extension of work previously carried out on the electrical conductivity of calcium oxide at low electric fields[1] In order to obtain activation energies for the conduction processes[2], it is necessary to determine the conductance at zero applied field as a function of temperature, but information of some value can be obtained from a study of the conductance of the cathode material at higher electric fields than those commonly employed Reports of investigations at high fields are much less numerous than those of conventional measurements, but the work of Danforth and Goldwater[3] and of Nakai, Inuishi and Tsung-Che[4] may be referred to Of interest is the recent investigation by Adams and Jacob[5] on strontium oxide the behaviour of its high-field conductance appears to be dissimilar to that of barium oxide, the form of the graph of conductance versus applied voltage depending strongly on the temperature of the oxide The present work on calcium oxide may be of interest in a general comparison with results from the other alkaline earth oxides

Two types of experimental tube have been used in the present work the calcium oxide samples were contained between nickel or between platinum cathode bases The construction and processing of the tubes have been described in a previous communication[1] Conductivity currents were measured on a galvanometer for applied potentials of up to 100 V d c , and characteristics of conductivity current versus applied potential were traced at various values of the sample temperature The conductance of the calcium oxide sample at an applied potential V was determined by taking the gradient of the characteristic at the relevant value of V

Fig 1 shows a typical series of current-voltage characteristics for a nickel-based sample of calcium oxide for the range of temperature T of 598–926° K , and Fig 2 shows the variation of the conductivity with the applied voltage for these curves Currents in the voltage- and temperature-ranges shown were stable, but at temperatures greater than about 1,000° K for this sample the application of potentials greater than 10 V was sufficient to cause gross instabilities due to breakdown Curves of similar form were obtained with platinum-based samples, although conductivity currents were smaller as the activation process was less effective For the sample giving the results in Figs 1 and 2, the conductivity plot obtained by plotting log σ_0 (where σ_0 is the zero-field conductivity) versus $1/T$ shows two approximately linear portions intersecting at about 700° K , above this temperature the Loosjes–Vink hypothesis[2] predicts that the current-voltage characteristics should be curved towards the applied potential axis, and below it they should be linear Such a difference in the form of the characteristics is, in fact, observed The general form of the variation of conductivity with applied potential in the high-temperature region is broadly the same as that found by Danforth and Goldwater[3] in pulsed current measurements on barium oxide, strontium oxide and the mixed oxide the

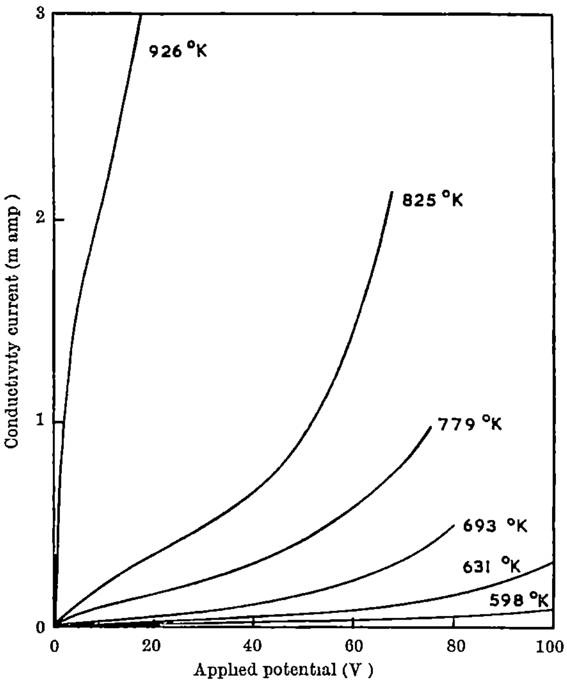

Fig 1 Conductivity current–voltage characteristics for a sample of calcium oxide

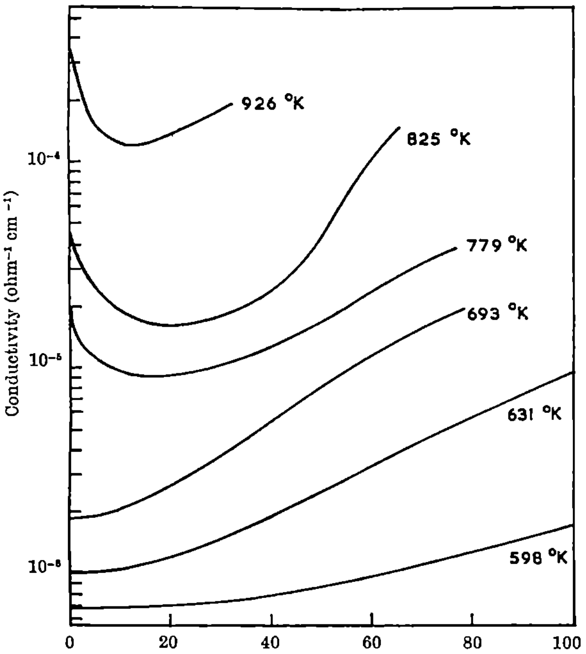

Fig 2 Conductivity as a function of applied voltage for calcium oxide

conductivity decreases to a minimum and then increases with increasing field An interesting feature of the characteristics is the increase in conductivity at high fields, which is observed throughout the temperature range Curvature of the current-voltage characteristics in this sense might be expected from a consideration of the Joule heating effect of the conductivity current, but an estimate of the orders of magnitude of the quantities involved shows that the curvature cannot be attributed solely to a heating effect In the range of temperatures above 700° K, where for this sample the conduction process is predominantly one of thermionic emission across the pores of the oxide, the increase of conductivity current with applied voltage is too rapid to be completely accounted for by the Schottky effect The fact that similar curves are obtained for nickel- and platinum-based samples indicates that the form of the characteristics is a property of calcium oxide rather than of any interface compound which may be formed between calcium oxide and the nickel cathode base

A detailed comparison between the results of different workers using the various oxides is not possible Among the difficulties involved is a satisfactory definition of the field across the porous specimen[5], and the possibility also exists of differences in the porosities of samples used by different workers, which may cause considerable differences in the shape of the characteristics[3]. The general conclusions reached as a result of the present work are that at low electric fields the shape of conductivity current-voltage characteristics for calcium oxide agrees with the predictions of the Loosjes–Vink hypothesis, at high fields an increase in conductivity is observed, similar to that previously observed in the other alkaline earth oxides and in the mixed oxide[3], and the field- and temperature-dependent effects obtained with strontium oxide[5] are not found with calcium oxide in the temperature-range investigated.

A Difference Band of a Fundamental and a Lattice Mode in the Infra-red Spectra of Lead and Other Carbonates

Lead carbonate, $PbCO_3$, crystallizes in the potassium nitrate structure, space group D_{2h}^{16}, with four molecules per unit cell[1] From crystallographic considerations, it follows that the carbonate ion occupies a site in the lattice of which the symmetry is C_s The degeneracies of ν_3 and ν_4 are removed by the perturbing crystalline field, and all the vibrational modes are active in the infra-red

'Vaseline' mulls of lead carbonate were prepared and the spectra were recorded with a Perkin–Elmer model 21 spectrometer fitted with sodium chloride optics The frequencies and assignments are given in Table 1 and the infra-red spectrum is shown in Fig 1

Table 1 FREQUENCIES AND ASSIGNMENTS OF THE INFRA-RED BANDS OF LEAD CARBONATE

Frequency (cm $^{-1}$)	Relative intensity	Assignment
2,405	vw	$\nu_1 + \nu_4$
1,731	w	$\nu_1 + \nu_3$
1,437	vs	ν_4
1,406	vs	
1,053	m vsp	ν_1
849	s sp	ν_2
824	vw	ν_2-lattice mode
690	sh	ν_3
678	s	

In agreement with the prediction based on the crystal structure, the degeneracies of ν_3 and ν_4 have been removed and the infra-red inactive ν_1 has become infra-red active

A small band occurs on the low-frequency wing of ν_2 of the spectra of the following salts

Lithium	carbonate	(work in this Laboratory)
Sodium	,,	,, ,,
Potassium	,,	(ref 2)
Lead	,,	
Calcium	,,	(ref 2)

Sodium	nitrate	(ref 2)
Lithium	,,	(work in this Laboratory)
Potassium	,,	,, ,,
Calcium	,,	,, ,,
Barium	,,	,, ,,
Strontium	,,	,, ,,

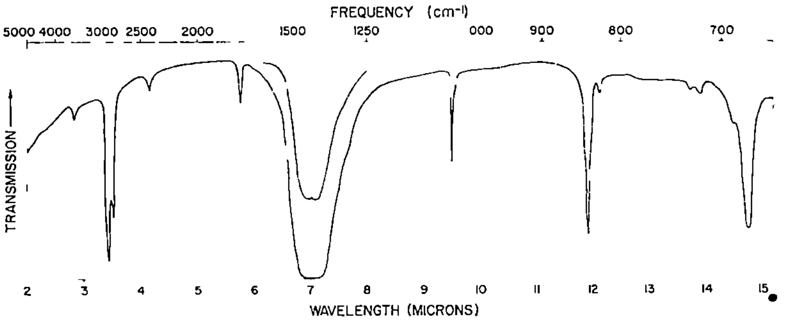

Fig 1 Infra-red spectrum of lead carbonate ('Vaseline' mulls) ν_4 is shown in detail with the 'Vaseline' bands compensated for by a 'Vaseline' sample in the reference beam of the spectrometer

The frequency difference between ν_2 and the small band is always of the order 10–30 cm $^{-1}$ An explanation of this phenomenon can be given on the following lines The ν_2 mode of planar XO_3^- ions can be described by a motion in which the central X atom moves perpendicular to the plane of the oxygen atoms This corresponds to movements in two directions in the crystal if the crystal contains a two-fold axis, and in one direction if a three-fold axis is present This directional movement is only present in the case of ν_2 It is evident that this situation greatly facilitates the transfer of energy between the ν_2 vibration and a translational lattice mode The result of this coupling is that a difference band appears of ν_2 and a translational lattice mode From these considerations it can be predicted that this difference band occurs in the infra-red spectra of all crystals containing flat XO_3 ions

CHEMISTRY

Products of the γ-Radiolysis of Aqueous Cystine Solutions

RECENTLY, Markakis and Tappel[1] determined the yields of cysteine, alanine, ammonia, hydrogen sulphide, sulphur and sulphate in hydrochloric acid solutions of cystine irradiated with γ-radiation from spent fuel elements However, their results indicate that especially at low doses ($< 10^6$ rads) not all the radiolytic products were identified The present communication describes the identification of products in cobalt-60 γ-irradiated unbuffered and acidified cystine solutions at relatively low doses

All solutions were made using doubly-distilled water and L-cystine (Mann-assayed grade from Mann Research Laboratories, Inc [α] = –216° in M hydrochloric acid) Oxygenation and deoxygenation of solutions were effected by bubbling oxygen and nitrogen respectively through the solutions during irradiation All irradiations were carried out at ambient temperature with a dose-rate of about 670 rads/min In order to inhibit cysteine oxidation 1 ml of 0 1 M N-ethyl-maleimide (NEM) was added to each solution (50 ml) after irradiation Cystine solutions (3×10^{-4} M) were concentrated (25 fold) at 30–32° C prior to spotting on paper for descending chromatography or electrophoresis Radiolytic products were detected on developed chromatograms and electrophoretograms using the polychromatic copper nitrate–ninhydrin reagent[2]

Table 1 R_A (R_F REL TO ALANINE) VALUES OF RADIOLYTIC PRODUCTS FROM CYSTINE

Compound	R_A* and (colour)†	R_A* and (colour)† of spot from irradiated solution
Cystine disulphoxide	0 41 (g–b)	0 38 (g–b)
Cystine	0 54 (g)	0 54 (g)
Cysteic acid	0 65 (p)	0 65 (p)
Cysteine sulphinic acid	0 80 (p)	0 78 (p)
Alanine	1 00 (p)	1 00 (p)
Cysteine (uncoupled with NEM)	0 94 (g)	0 94 (g)
Cysteine (coupled with NEM)	1 05 (r)	1 04 (r)

*, in $EtOH/H_2O/H_2SO_4$ (80 20 0 5)
†, g = grey, b = brown, p = purple, r = rust

In most cases excellent separation of ninhydrin-positive products was obtained using ethanol/water/sulphuric acid (80 20 0 5) for chromatography Although development with ethanol/water (80 20) and butanol/acetic acid/water (4 1 5) also yielded fair separation of products, the use of a strongly acidic solvent seemed desirable in light of the ease of hydrolysis of cystine disulphoxide The chromatographic data and spot colours (Table 1) suggest that cystine disulphoxide, cysteic acid, cysteine sulphinic acid, alanine and cysteine are radiolytic products

Although the reaction between NEM and thiols is known[3] to proceed more slowly the lower the pH, the 'uncoupled cysteine' spot was not observed in the chromatograms of acidified cystine solutions provided they were allowed to react with NEM for at least one day prior to spotting The presence of cysteic and cysteine sulphinic acids in unbuffered solutions was confirmed by paper electrophoresis at a number of pH values Some confirmation of the identification of cystine disulphoxide in certain irradiated solutions follows from the observation that the 'disulphoxide spot' was absent in chromatograms of aliquots (containing no NEM) to which cysteine had been added prior to chromatography This is to be expected since it has been shown[4] and confirmed in the present work that cysteine reacts with cystine disulphoxide to form cystine and cysteine sulphinic acid

No precise quantitative analysis of the products was attempted and the very approximate G-yields listed (Table 2) were deduced from visual comparison of the spots from irradiated solutions with those from appropriate amino-acid solutions

In hydrochloric acid solutions estimation of the amounts of cysteic acid on chromatograms developed with the ethanol/sulphuric acid solvent was not possible owing to interference from a grey-blue spot with R_A of 0 7 However, fair separation of the cysteic acid/cysteine sulphinic acid fraction from other species present was effected with ethanol/water (80 20) When this solvent was used, the irradiated solutions were first dried to remove hydrochloric acid and redissolved in 10^{-2} M acetic acid prior to spotting on paper

Table 2 PRODUCTS OF IRRADIATED 3×10^{-4} M CYSTINE SOLUTIONS (DOSE OF 8×10^4 RADS)

[Acid]	Initial degree of oxygenation*	Products† and (approx G-yield)				
Unbuffered	O	RSO_2SR‡	RSO_3H (1 1),	RSO_2H‡	RSH‡	RH‡
Unbuffered	A		RSO_3H (1 2),	RSO_2H‡	RSH (0 9),	RH‡
Unbuffered	D		RSO_3H‡	RSO_2H (0 1),	RSH (0 9),	RH‡
0 04 M HCl	O	RSO_2SR‡	RSO_3H (0 3)	RSO_2H‡	RSH (0 5),	RH‡
0 04 M HCl	A		RSO_3H (0 3),	RSO_2H‡	RSH (0 6),	RH‡
0 04 M HCl	D			RSO_2H‡	RSH (0 7),	RH‡
0 02 M H_2SO_4	O	RSO_2SR (0 4),	RSO_3H (1 5),	RSO_2H‡		RH‡
0 02 M H_2SO_4	A	RSO_2SR‡	RSO_3H (1 5),	RSO_2H‡	RSH (0 4),	RH‡
0 02 M H_2SO_4	D		RSO_3H‡	RSO_2H‡	RSH (0 5),	RH‡

* O, Oxygenated, A, aerated, D, deoxygenated
† RSO_2SR, Cystine disulphoxide, RSO_3H, cysteic acid, RSO_2H, cysteine sulphinic acid, RSH, cysteine, RH, alanine
‡ G-yield < 0 1

Discussion of the results is simplified by assuming that the following reactions occur

$$\begin{array}{lcll} RSSR + OH & \rightarrow & RSOH + RS & (1) \\ RSSR + H & \rightarrow & RSH + RS & (2) \\ RS + RS & \rightarrow & RSSR & (3) \\ RS + X & \xrightarrow{O_2} & RSO_2SR + Y & (4) \\ H + O_2 & \rightarrow & HO_2 & (5) \\ RSH + RSO_2SR & \rightarrow & RSO_2H + RSSR & (6) \\ RSH + RSOH & \rightarrow & RSSR + H_2O & (7) \end{array}$$

The sulphenic acid formed in (1) is assumed to be oxidized by hydrogen peroxide (or HO_2) through the sulphinic acid to cysteic acid Reactions (2) and (7) would explain the low yields of cysteic acid in deoxygenated solutions In aerated solutions apparently oxygen is depleted to such an extent (preliminary experiments indicate that in unbuffered aerated solutions 18 per cent of the initial oxygen content remains after 80,000 rads) that some hydrogen atoms are available for reaction (2) Reaction (6) helps to maintain high yields of cysteic acid in aerated solutions and, of course, ensures that high yields of cysteine and cystine disulphoxide are never detected in the same irradiated solution The low yields of cystine disulphoxide and cysteic acid in hydrochloric acid solutions is presumably in part due to chloride ion-inhibition of reaction (1) However, the mechanism of the inhibition must remain obscure until the grey-blue spot observed on chromatograms of irradiated hydrochloric acid solutions of cystine is identified The low yield of cystine disulphoxide in unbuffered solutions is not unexpected owing to rapid hydrolysis of the disulphoxide in these solutions Although the accuracy of the yield-estimates is poor, the results seem to indicate that yields may depend on the *p*H of the solutions It is possible that the observed increase in yield of cysteine and the decrease in yields of cysteic acid in unbuffered solutions is due to participation of the O_2^- ion which could conceivably reduce cystine to cysteine

Regarding the possible effect of dilute hydrogen peroxide on cystine, it has been found that chromatograms of cystine (3×10^{-4} *M*)–hydrogen peroxide (2×10^{-4} *M*), which had been concentrated in the normal manner, exhibited only one faint spot with R_A characteristic of the disulphoxide

We are indebted to Mr A Casselman and Dr R Greenhalgh for advice on electrophoresis and chromatography

Inhibition of the Formation of 3,4-Benzpyrene during Hydrocarbon Combustion

It is well known that polycyclic hydrocarbons including the carcinogen 3,4-benzpyrene occur in association with the carbonaceous deposits or smokes resulting from the incomplete combustion of a wide variety of organic materials Thus 3,4-benzpyrene has been identified in soots, carbon black, certain smoked foods, cigarette- and tobacco-smoke and in the exhaust smoke of Diesel engines The mode of formation of 3,4-benzpyrene has been reviewed by Badger *et al* [1], who have suggested possible intermediates during the pyrolysis of organic compounds, and have pointed out that the observed products can be accounted for by secondary reactions involving initial or primary free radicals A recent examination of the products from the pyrolysis of petroleum hydrocarbons by electron spin resonance supports the view that free radicals participate, the phenalenyl radical[2] has been identified

The subject of formation of carbon in flames has attracted attention in recent years, the mechanism is still obscure but polycyclic hydrocarbons are often associated with the carbonaceous material formed The present work was undertaken to determine whether the formation of 3,4-benzpyrene can be inhibited during hydrocarbon combustion It is well established that nitric oxide exerts a remarkable inhibiting effect on the chain-decomposition of some hydrocarbons[3] A substance was sought which would give rise to nitric oxide as a product of pyrolysis It is known[4] that the carbon zone in a diffusion flame is a region where the hydrocarbon is decomposed thermally in the absence of oxygen (although OH radicals do reach this zone) and it seemed plausible that the production of nitric oxide within this zone might lead to inhibition of free-radical reactions leading to polycyclic hydrocarbons Grey *et al* [5] have investigated the thermal decomposition of nitroalkanes and have found nitric oxide in the products (with formaldehyde and some nitrogen dioxide, etc)

In the present work, known amounts of nitroethane were introduced into a stream of commercial propane ('Bottogas') which was burned as a laminar diffusion flame in air The air supply was reduced to give heavy soot formation in the absence of additive and the soot was collected, mainly on a brass target placed just above the flame, but also from the walls of the surrounding 'Pyrex' chimney A weighed amount of

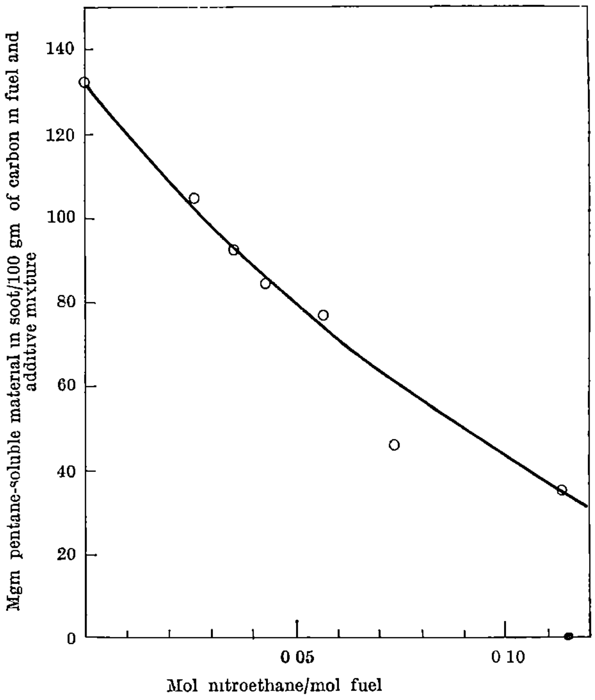

Fig 1

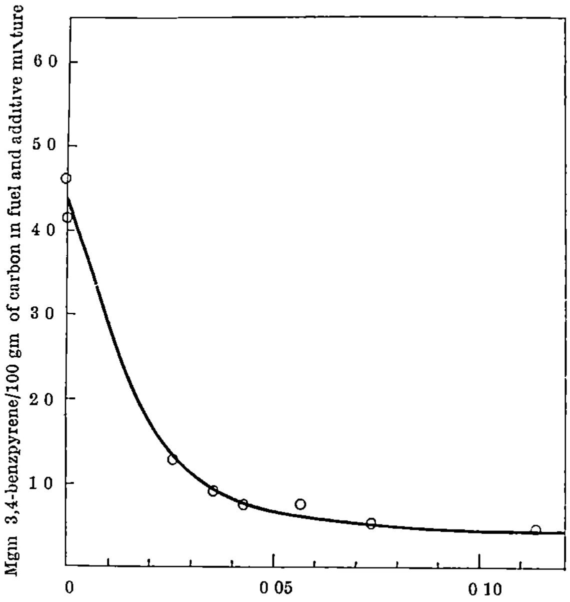

Fig 2

soot was extracted with A R chloroform in a Soxhlet apparatus for about 3 hr The solvent was removed by distillation in an atmosphere of nitrogen and the residue was extracted repeatedly with *n*-pentane The extract was filtered and the *n*-pentane removed in an atmosphere of nitrogen, the residue was weighed and reported as mgm *n*-pentane-soluble material per 100 gm of carbon input in the fuel + additive mixture (Fig 1) The 3,4-benzpyrene content of the *n*-pentane-soluble material was determined by the method described by Sawicki *et al* [6] This depends on the fact that 3,4-benzpyrene in a concentrated solution of sulphuric acid exhibits a characteristic peak in its fluorescence spectrum at 545 mμ when irradiated by ultra-violet light of activating wave-length 520 mμ This peak is unaffected by the presence of other polycyclic hydrocarbons The fluorescence spectrum was obtained by means of an Aminco-Bowman spectrophotofluorometer In order to eliminate the effect of concentration quenching, the concentration of total polycyclic aromatic hydrocarbons was kept constant in each determination at 50 μgm/ml Calibration was effected using a pure sample of 3,4-benzpyrene It can be seen (Figs 1 and 2) that small additions of nitroethane lead to a marked reduction in the formation of *n*-pentane-soluble material in the soot and in the amount of 3,4-benzpyrene

Nitro-compounds (including nitroethane) are known to raise the cetane number when added in small amounts to Diesel fuels[7] Although the present work has not been extended to engine studies we suggest that a reduction in emission of 3,4-benzpyrene from Diesel engines might be expected when nitroethane and similar additives are employed

It has been found by a number of workers and recently confirmed by Pichler and Deschner[8] that no 3,4-benzpyrene is present in soot-free Diesel exhaust gases but under conditions of low revolutions and high load it does occur in the exhaust smoke Although Diesel engines are probably relatively minor contributors to atmospheric pollution compared with industrial and domestic fuel-burning equipment[9], any attempt to reduce the emission of 3,4-benzpyrene in Diesel exhaust smoke, either by attention to engine design and maintenance or by chemical means, would be valuable

We are indebted to the Coal Tar Research Association for the gift of a pure sample of 3,4-benzpyrene and to the Department of Surgery of the Medical School for permission to use the Aminco-Bowman spectrophotofluorometer

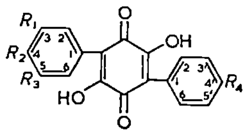
A Novel Type of Antioxidant related to Polyporic Acid

IN the inhibition of the autoxidation of 1,4-dienes, for example, linoleic acid and its esters, it is generally assumed that polyphenolic compounds act as chain breakers in accordance with the mechanism $RO_2 + AOH \rightarrow ROOH + AO$, where RO_2 is the chain propagating peroxy radical and AOH is the antioxidant The efficiency of the latter is determined not only by the rate of the inhibitory reaction but also by the stability of the intermediate AO radical[1]. Recently it was shown that certain polyhydroxy flavones[2] exhibit a remarkably high antioxidant efficiency In this work, which was carried out with the view of finding better antioxidants for fat-containing foods, attention was concentrated on a group of compounds which were related to certain terphenyl quinones occurring in some edible fungi They can be represented in terms of the following structure



The compounds which were investigated include polyporic acid (R_1, R_2, R_3, R_4 = H), atromentin (R_1, R_3 = H, R_2, R_4 = OH) and leucomelone (R_1, R_2, R_4 = OH, R_3 = H), which occur in certain fungi and lichens (A detailed discussion concerning the structure of leucomelone will be presented elsewhere)

In addition, a number of related compounds which do not occur naturally were synthesized They include trihydroxypolyporic acid (R_1, R_2, R_3 = OH, R_4 = H) and its *tert*-butyl derivative (R_1, R_2, R_3 = OH; R_4 = *tert*-butyl)

The synthesis of leucomelone has been described by Akagi[3], and in this investigation a similar method was used for the synthesis of the compounds mentioned above

In the preparation of the new trihydroxypolyporic acids the reaction of 2,5-dichlorobenzoquinone with the appropriate *N*-nitrosoacetanilide gave 2,5-dichloro 3-phenyl 1,4-benzoquinone and 2,5-dichloro 3-(4-*t*-butylphenyl) 1,4-benzoquinone, which were then treated with diazotized 3,4,5-trimethoxyaniline The dichloroterphenyl quinones thus prepared were hydrolysed to the corresponding dihydroxyquinones Demethylation of the dihydroxy terphenyl quinones with a mixture of hydrobromic acid and acetic acid gave the pentahydroxyquinones directly, reductive demethylation followed by oxidation was not attempted

The antioxidant activity of the compounds was tested in pure linoleic acid and in pure methyl linoleate at a temperature of 25° C Uptake of oxygen was followed with conventional Warburg apparatus and this was correlated with peroxide formation, which was determined by means of an iodometric method[4] A special test was used for the determination of antioxidant efficiency in the presence of metal catalysts, using ferrous phthalocyanine in ethyl benzoate solutions as standard The results indicated that polyporic acid had no significant antioxidant activity, while atromentin and leucomelone were comparable with conventional antioxidants, for example, propyl gallate, for the inhibition of fat autoxidation The new antioxidants 3,4,5-trihydroxypolyporic acid and 4′-*tert* -butyl 3,4,5-trihydroxypolyporic acid showed outstanding activity In linoleic acid these compounds gave protection factors which were, respectively, about ten and twenty-five times that obtained with propyl gallate It should be noted that the *tert* -butyl substituent substantially increases the solubility of the trihydroxypolyporic acid in higher fatty acids and their esters

Anti-leukæmic activity of unsubstituted polyporic acid was reported recently[5], it would be interesting to compare the polyhydroxypolyporic acids which show greater antioxidant activity

The work was supported by the U S Department of Agriculture *P.L* 480 counterpart funds

Ionic-Covalent Bonding in Crystals

An attempt[1] to resolve misunderstandings regarding ionic-covalent bonding in solids has been criticized in a recent article by Mooser and Pearson[2] It should be pointed out, however, that their discussion of formal ionicity is limited to the simple and well-known case of atoms which each contribute one electron to a two-electron bond, and cannot be applied as it stands to 'dative bond' systems (such as are found in the zinc blende structure and in many other types of crystal, as well as in co-ordination complex molecules) In such systems formal covalency, defined as a state in which bonding electrons are equally shared between bonded atoms, can only be achieved by a donor–acceptor relationship with associated charge separation

The main point in my communication[1] was the importance of the neutral-bond state (defined as that with zero charge separation) as the logical zero for the scale of electronegativity (It should be noted that this is generally applicable, thus it holds for bonds in diatomic molecules, since for such molecules neutral-bonded and formally covalent states are identical) This suggests that 'ideal covalency' (so termed for want of a better name) is associated with zero charge separation rather than with equal sharing of electrons If this is so, the difficulty pointed out by Mooser and Pearson regarding the zero of the scale of bond ionicity used in my communication[1] can readily be resolved It may well be that some revision of the accepted definition of the covalent bond on these lines is needed However, in terms of the definitions used, the conclusions regarding charge separation presented in ref 1 are still valid In this connexion the concluding statement by Mooser and Pearson that "any attempts such as have been made to determine effective charges from formal bond ionicities are bound to fail" is certainly not a dogmatically required belief It is my opinion, on the contrary, that useful qualitative information regarding charge separations in crystals can be obtained, although, for obvious reasons, some of which are referred to in my earlier communication, no quantitative estimates are as yet possible

C H L Goodman
Standard Telecommunication Laboratories,
London Road, Harlow, Essex

---

[1] Goodman, C H L , *Nature*, **187**, 590 (1960)

[2] Mooser, E , and Pearson, W B , *Nature*, **190**, 406 (1961)

Goodman's comments on our recent article[1] in no way affect our views on the subject of ionic-covalent bonding as outlined there Since it is obvious, however, that Goodman is misinterpreting these views, we should like to stress once again the following points

(1) The 'effective bond ionicity' is defined in terms of the actual charges associated with the constituents of a compound It is, therefore, a physical quantity which can, at least in principle, be measured

(2) The 'formal bond ionicity' is a purely theoretical concept It is, in fact, an abbreviation with which to indicate to what extent various arbitrarily chosen valence structures are mixed to describe the bonding in a molecule or a solid Contrary to Goodman's remark, the formal bond ionicity is defined also for 'dative' bonds

(3) The covalent bond is defined as arising from the sharing of two electrons between two bonded atoms It does not specify the charges associated with these atoms and a covalent valence structure cannot, therefore in general, be taken as the zero of the bond-ionicity scale

(4) All the definitions given by us[1] and repeated here are in agreement with chemical tradition The intention of our article was merely to point out that two different meanings are currently attached to the term 'bond ionicity' To distinguish between them, we introduced the names effective and formal bond ionicities

BIOCHEMISTRY

Lipase Activity in the Slow- and Fast-contracting Leg Muscles of the Cockroach

THE recent work of Becht and Dresdon[1] and Smit[2] has brought to light certain histological and physiological features of the slow- and fast-contracting mesothoracic leg muscles of the cockroach, *Periplaneta americana* Smit[2] has shown that the slow-contracting muscle fibres contain more lipids and possess a stronger reducing capacity for methylene blue than the fast-contracting ones Histochemical investigation of these two types of fibres[3] has shown that there is more lipase activity in the slow-contracting muscles Here we report the results of a quantitative investigation of lipase activity in the slow- and fast-contracting leg muscles of the cockroach

Only the metathoracic and mesothoracic leg muscles of the male and female cockroaches were used According to Becht and Dresdon[1] the muscles 136, 137 and 135*a* and *c* (Carbonell's numbering) are fast-contracting and 135*b*, *d* and *e* are slow-contracting The slow muscle in this case is the tergo-trochanteral muscle, which is an exceptionally large muscle passing down the coxa to be attached to the trochanter The fast muscles which are the extensors, and act antagonistically to the above muscle, arise from the coxal rim and are attached on the coxo-trochanteral joint These two types of muscles were carefully dissected and removed separately from the coxa of the leg into separate ice-cold watch-glasses and weighed Separate aqueous extracts of the above samples of muscles were prepared at 4° C The extract was centrifuged at 2,500 r p m for 5 min and the supernatant was used as the enzyme material in each case The method used for the assay was adopted from Martin and Peers[4] using a Warburg apparatus Tributyrin was used as substrate with a bicarbonate–carbon dioxide buffer system of *p*H 7 4 at 37° C The reaction flask contained 1 5 ml 0 025 *M* bicarbonate solution and 1 ml enzyme solution in the main chamber and 0 5 ml substrate (4 per cent v/v tributyrin in 0 0148 *M* bicarbonate solution emulsified by shaking with a drop of 'Tween 80') in the side arm The flask and manometer were gassed for 3 min with a mixture of 95 per cent nitrogen and 5 per cent carbon dioxide After equilibrating the flask in the constant temperature water-bath of the apparatus for 10 min the substrate was tipped and the initial readings were taken after 3 min The subsequent readings were taken after a 30-min interval for 1 hr Lipase activity was calculated on the basis of the protein content of the enzyme solution used and is expressed as µl carbon dioxide / mgm protein / hr Protein was estimated by the micro-Kjeldahl steam-distillation method[5]

Table 1 LIPASE ACTIVITY IN THE SLOW- AND FAST-CONTRACTING LEG MUSCLES OF THE COCKROACH

Tissue	Lipase activity* (µl CO_2/mgm protein/hr) Male	Female
Slow muscle	129 31	81 43
Fast muscle	75 65	68 47

*Average of 12 experiments

From the results obtained it is evident that the slow-contracting muscle has a higher lipase activity than the fast-contracting muscle It is also seen that the activity of the enzyme in the same muscle is considerably lower in the case of the female than that in the male Again the difference between the concentrations of the enzyme in the two types of muscle is more in the male than in the female A histochemical study[3] of lipase and certain oxidative enzymes in these muscles also indicated a correspondingly sharp difference in the amount of these enzymes present in these two types of muscles, the slow muscles having more of them The greater concentration of the enzyme, lipase, in the slow- and fast-contracting muscles could be well correlated with the higher lipid content of these muscles, the slow muscle fibres being more pigmented and showing considerably greater ability to stain for fat than the fast muscle fibres The higher concentration of lipase and the greater fat content of the slow muscle, which could indulge in sustained contractions for considerably longer periods than that of the fast one, is suggestive of more fat being split for utilization for energy in the former The higher lipase value in the muscles of the male could also be regarded as an index of the greater capacity for sustained activity involving greater fat utilization in the male

Comparison of the Serum Protein Fractions of the Developing Chicken Embryo by the Technique of Starch-Gel Electrophoresis

SEVERAL workers have investigated the serum protein composition of the developing chicken embryo, by moving boundary[1-3] and paper electrophoresis[4,5] The ultracentrifugal analysis of the serum proteins of the early stage of embryonic development of chicken, as investigated by two groups of workers, are not in agreement in regard to the complexity of the molecular structure in that stage[1,2] Electrophoretic investigation does show, however, the multiplicity of the components in the early stage, although no complete agreement exists in regard to the number of the components and their relationship to those found in newly hatched and adult birds[6] Thus Hradec and Lemez[4] reported that the serum proteins of chicken embryo undergo considerable qualitative transformation throughout the development The technique of starch-gel electrophoresis suggested by Smithies[7] enables one to detect in the serum pattern fractions that cannot be observed by other methods of electrophoresis The pooled sera of five different age-groups of chicken embryo, incubated for 10, 13, 16, 19, and 21 days were examined by the technique of starch-gel electrophoresis, run simultaneously on the same gel The electrophoresis was performed on a vertical tray[8] for 18 hr , using borate buffer of *p*H 8 6 and a field-strength of 4 V /cm Twelve fractions could be distinguished on the pattern of the serum from the embryo aged 21 days as is shown in Fig 1 (two pre-albumins are not shown), as was also indicated in ref 6 At least nine components (except the pre-

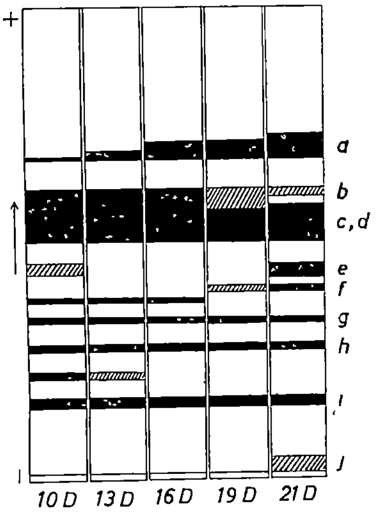

Fig 1 A schematic representation of the starch-gel electrophoretic pattern of serum of the developing chicken embryo The letters *a* to *j* refer to albumin and γ-globulin The numbers 10, 13 16, 19 and 21 indicate the days of incubation The striped bands represent the areas that could scarcely be distinguished on the original patterns

albumins) could be distinguished on the pattern from the 10-day old chicken embryo, of which at least seven components corresponded in mobility to those found in the day-old chick The patterns from the sera of 13, 16, and 19 days of incubation also showed similarity in pattern to that of the day-old chick A component present in the sera of the 10-day and 13-day old embryo and situated somewhere between components *h* and *j* of 21-day old embryo was not distinguishable in the sera of the older embryos The results presented here indicate that apparently with the exception of γ-globulins and some other fractions, as demonstrated in Fig 1, almost all other components present in the day-old chick are present in the serum of 10-day old embryo, as is revealed by the method of starch-gel electrophoresis, and that the transformation occurring throughout this period of development is apparently of a quantitative rather than qualitative nature

A Zinc-requiring Alkaline Phosphatase in the Ventral Lobe of the Rat Prostate

Zinc has been shown to play an important part in the activity of phosphatases$^{1-7}$ We have now found evidence for the existence of a zinc-dependent alkaline phosphatase in the ventral lobe of the rat prostate The hydrolysis of 0 002 *M* adenosine monophosphate in 0 065 *M* *tris*-(hydroxymethyl)-amino methane buffer at *p*H 9 4 by homogenates of the gland was progressively inhibited by increasing concentrations of zinc (Fig 1)

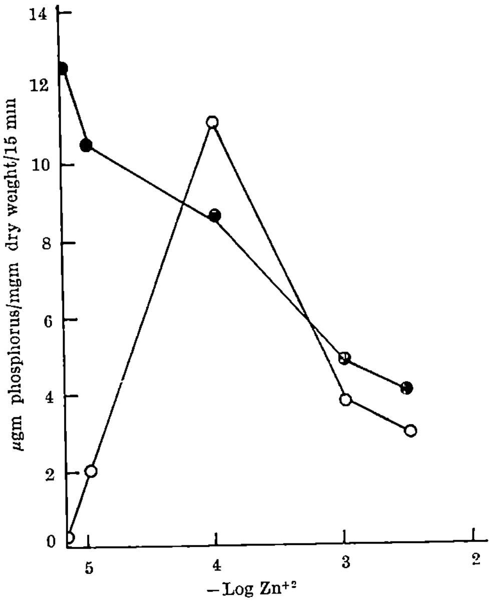

Fig 1 Effect of zinc on the hydrolysis of adenosine monophosphate by prostatic homogenates from the rat ventral lobe The effect of the addition of zinc to a homogenate dialysed for 3 hr against *tris* buffer at *p*H 7 0 at 0° (●) and the addition of 10^{-3} *M* EDTA to the homogenate followed by dialysis for 3 hr (○) Phosphatase activity was measured by the method of Fiske and Subbarow (ref 9) Incubation mixture contained 0 5 ml 0 25 *M* *tris* buffer at *p*H 9 4, 0 1 ml 0 04 *M* adenosine monophosphate, 0 9 ml water, 0 5 ml homogenate, the mixture was incubated for 15 min at 37°

The addition of ethylenediamine tetraacetic acid (EDTA) at concentrations greater than 10^{-3} *M* to homogenates inhibited the phosphatase activity by 30–50 per cent When EDTA treatment was followed by dialysis against *tris* buffer at *p*H 7 4, the inhibition was practically 100 per cent

The addition of zinc acetate restored the activity of the inhibited enzyme to about 80 per cent of its original value Sodium acetate had no effect After reactivation of the enzyme, increasing the concentration of zinc caused normal inhibition (Fig 1)

In contrast to zinc ions, magnesium and calcium ions reversed to a slight extent the inhibition caused by EDTA and dialysis Since the logarithms of the stability constants for EDTA complexes of zinc, calcium and magnesium are in the ratio 16 3 10 6 8 7 (ref 8), the greater activity of zinc did not depend on the binding capacity of EDTA

We wish to thank the British Empire Cancer Campaign for a grant to support the work

Demethylation of the Plant Œstrogen Biochanin *A* in the Rat

GENISTEIN and biochanin *A*, 4′-methylgenistein, have been isolated from red clover and have been found to account for the œstrogenic activity of this plant[1] Though their œstrogenic potency is very weak, the substances may nevertheless be of importance in animal physiology because they are ingested in considerable amounts by grazing animals

Very little is known about the metabolic transformations of these compounds Biochanin *A* was found to be demethylated to genistein by the influence of rumen micro-organisms[2]. The present investigation has been undertaken with the aim of studying the metabolism of biochanin *A* in rats The compound was synthesized by known methods[3] and labelled with tritium[4]

Each of twenty rats was injected intraperitoneally with 25 mgm of a fine suspension of biochanin *A* in saline Urine and fæces were collected separately An ether extract of the urine was prepared and fractionated on a 'ChroMax' preparative paper column (LKB, Stockholm) with butanol/2 *N* ammonia (1 1) as eluant Radioactive biochanin *A* (12 7 mgm) and genistein (3 5 mgm) were isolated from the eluates Their melting points and ultra-violet and infra-red absorption curves coincided with corresponding values of authentic test samples Both these isoflavones were isolated in the same way from an ether extract of fæces

The demethylation of biochanin *A* to genistein was demonstrated by incubation experiments with rat liver slices The experiments were performed as follows liver slices, 1–1 2 gm dry weight, were prepared by hand and incubated with 6 μmoles of tritium-labelled biochanin *A* (specific activity 2 μc per μmole) in 20 ml *p*H 7 4 Krebs–Ringer phosphate buffer The incubation was performed at 37° C for 2 hr To the volume of the incubation medium was added 4 times this volume of alcohol The mixture was centrifugated The slices were homogenized and extracted with 80 per cent alcohol. The solvent was evaporated in a partial vacuum under nitrogen The dry residues were dissolved in 5 per cent sodium bicarbonate solution and extracted with ether. The sodium bicarbonate solution contained conjugates of the isoflavones The ether extracts were evaporated and subjected to paper chromatographic analysis on Whatman No 3 paper, using benzene/acetic acid/water (165 34 1) as the solvent system The isoflavones were located by their absorption in ultraviolet light The chromatograms were cut into strips, eluted with 80 per cent alcohol, and the eluates analysed for radioactivity in a liquid scintillation counter Ekco *N* 612 at a temperature of $-20°$ C (Fig 1 *A*) The radioactive eluates from the genistein spots on the chromatograms were rechromatographed in different solvent systems[2] They were found to coincide with genistein in all the systems Incubation experiments were also performed as above with intestine contents and labelled biochanin *A* No radioactivity except from the biochanin *A* spots could be found on these chromatograms (Fig. 1 *B*) Traces of the radioactivity remained at the starting point on the chromatograms both with material from incubation experiments and controls, probably due to insufficient elution

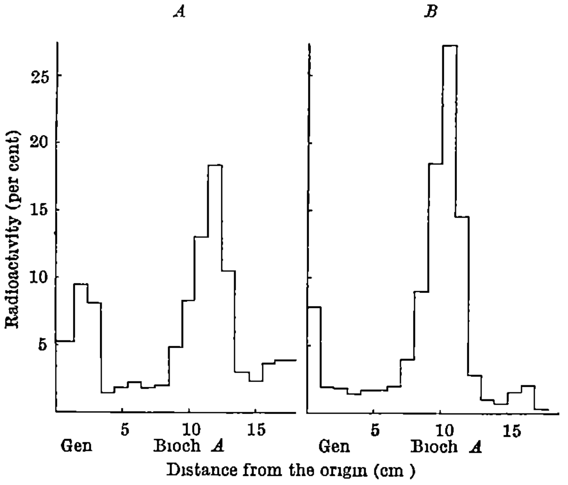

Fig 1 The distribution of radioactivity on paper chromatograms with biochanin *A*, incubated with liver slices (*A*) and intestine contents (*B*) The radioactivity of the eluates is expressed as percentages of the sum of recovered activity from the chromatogram and indicated on the abscissa The positions of the test substances are indicated below the diagrams

These preliminary experiments show that a demethylation process occurs in the liver Several other aromatic ethers have been found to be split in the liver[5] It is known that methylation of the hydroxyl groups of many synthetic œstrogens retards or decreases their œstrogenic action[6] It is, therefore, generally believed that these molecules have to be demethylated before becoming active It is not known if the presence of free —OH groups is also necessary for the action of the isoflavones However, genistein with three free —OH groups is the most active one of the four œstrogenic isoflavones[7].

Work on the demethylation of methyl ethers of other œstrogens and with different experimental animals is now in progress

Enhancement of Steroidogenesis by Rat Adrenal Slices *in vitro* with Œstradiol-17-β

RECENT experiments have shown that the concentration of corticosterone in adrenal vein blood of female rats is 2 4 times that in male rats[1] The possibility that this difference is due, at least in part, to the direct action of œstrogen on the adrenal cortex is the subject of the present study.

Male or female rats of the Sherman strain, weighing 120–150 gm , were maintained in a constant-temperature room for at least one week prior to use. Female rats were bilaterally oophorectomized at 21–30 days of age and used about 6 weeks later Adrenal slices were prepared according to a modification[2] of the technique of Saffran and Schally[3] The final incubation medium was modified by addition of U S P adrenocorticotrophic hormone (5 milliunits/100 mgm adrenal tissue) and œstradiol-17-β 7 5 × 10^{-6} *M* In each experiment, comparable tissue pools were treated by addition of the appropriate diluent alone (saline and propylene glycol respectively). Corticoid yields were determined by ultraviolet absorption and expressed as μgm./100 mgm. adrenal tissue.

The effects of œstradiol addition are shown in Table 1. Significant increments in corticoid production were obtained on addition of œstradiol to male adrenal slices in the absence or presence of adrenocorticotrophic hormone. No effects were observed with female adrenal slices. However, increased corticoid yields, comparable with those obtained with male tissue, were found when adrenal tissue from oophorectomized female rats was employed.

Table 1. EFFECTS OF ŒSTRADIOL ON STEROIDOGENESIS *in vitro*

Adrenal source	No. of observations	ACTH (m.U.)	Corticoid yields* (μgm./100 mgm.) Control	Œstradiol
Male	4	0	9·2 ± 0·6	16·4 ± 1·1†
	4	5	14·9 ± 1·7	20·3 ± 1·8†
Female	4	0	19·1 ± 1·6	20·1 ± 2·0
	4	5	24·8 ± 1·4	25·9 ± 1·0
Oophorectomized female	4	0	11·8 ± 0·8	17·8 ± 0·5†
	4	5	15·5 ± 0·9	19·8 ± 0·9†

* Mean ± standard error.
† Significant at the 1 per cent level.

Administration of adrenocorticotrophic hormone or a standardized stress to adult female rats has been shown to result in significantly higher peripheral plasma corticosterone concentrations than those obtained in male animals[1]. Yates *et al.*[4] have demonstrated that the capacity of liver homogenates from female rats to reduce the *A* ring of corticosterone is significantly greater than that of male animals. These authors have proposed that this more rapid metabolism of steroid is the principal mechanism responsible for greater adrenal secretory capacity in the female rat. The present findings indicate that œstrogen may also affect steroidogenesis directly and independently of its action on liver metabolism. A comparable degree of stimulation was found when œstradiol was added to either male or oophorectomized adrenal tissue. The failure to demonstrate a stimulatory effect on adrenal slices from intact female animals suggests that such tissue has already been subjected to maximal œstrogenic stimulation. The significantly higher control corticoid-levels obtained with intact female adrenal tissue compared to tissue from the other sources are consistent with this hypothesis.

Utilizing an essentially similar assay system, McKerns[5] found that the addition of œstradiol-17-sodium sulphate *in vitro* to intact male or female adrenal tissue resulted in no change in corticoid production. The discrepancy between his findings and those of the present work perhaps may be explained by differences in either the form or the dose of œstrogen added.

These results will be discussed in greater detail in a subsequent publication. This study was supported by a research grant (*A*-3370) from the U.S. Public Health Service.

Female Rat Preputial Glands as a Source of β-Glucuronidase

THE preputial gland of the adult female rat has been shown by Beyler and Szego[1] to be an extremely rich source of β-glucuronidase. However, it may not generally be realized that laboratories needing a steady supply of this enzyme and having access to a rat colony have a cheap and readily available source. Adult female rats which are being discarded can be used, and the two glands, each weighing approximately 50 mgm., are easily dissected free from the surrounding tissue (Fig. 1).

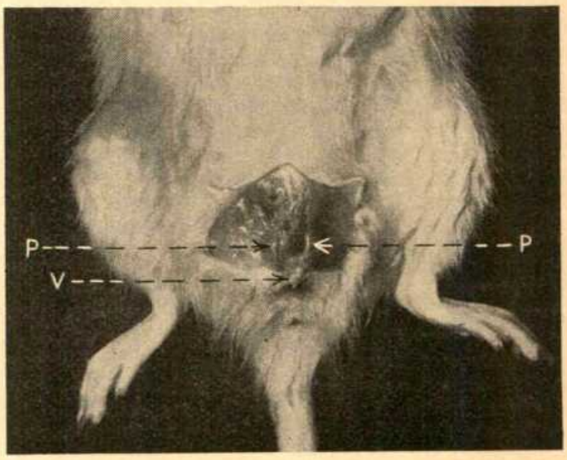

Fig. 1. Adult female rat dissected to show preputial glands. *P*, Preputial gland; *V*, vagina

Homogenization and extraction are then carried out as described by Levvy, McAllan and Marsh[2], though only one ammonium sulphate precipitation is necessary. An equal volume of saturated aqueous ammonium sulphate solution is added to the supernatant obtained, at the end of stage 2 (ref. 2). The ensuing precipitate, after separation from the aqueous phase, is then dissolved in a suitable quantity of 0·1 *M* sodium acetate buffer, *p*H 5·2, so that the resulting solution contains 0·5–1 × 10^6 Fishman units of β-glucuronidase per ml. The enzymic activity of the preparation is assayed by the method of Talalay, Fishman and Huggins[3]. The enzyme solution is stored in the deep freeze and deteriorates only slowly. It does not contain phenolsulphatase, as determined by the method of Roy[4].

The total working time involved in the preparation and assay of one batch is about 2 hr.

Extracts of β-glucuronidase, prepared in this manner from adult female rat preputial glands, have been used for more than four years in the enzymic hydrolysis of steroid glucuronides, notably those of pregnanediol and pregnanetriol.

Use of Phenol in determining Chromatographic Purity

WATER-SATURATED phenol is a well-known solvent for the paper chromatographic separation of polyphenols and was, for example, one of the solvents used by Roberts and Wood[1] for the two-dimensional paper chromatographic separation of tea-leaf polyphenols. This solvent was, however, later discarded in favour of water[2], or preferably 2 per cent acetic acid[3].

The use of 75 per cent (w/v) aqueous phenol (or *m*-cresol saturated with water) has proved to be of inestimable value in determining the chromatographic purity of various flavonoid compounds isolated in this laboratory. A fraction isolated from rooibos tea (*Aspalathus acuminatus*) and suspected of consisting solely of isoquercitrin was found by chromatography in phenol to consist of two major flavonoid components even though the material was chromatographically homogeneous in *n*-butanol/acetic acid/water (4:1:2·2 v/v), in water, in 15 per cent acetic acid, in ethyl acetate saturated with water, in propan-2-ol/water (1:3·5 v/v), and in chloroform/butan-2-ol/water (2:4:4 v/v). Separation also took place in 60 per cent acetic acid but was incomplete and not very convincing. The identity of the second component is still under investigation.

In the isolation of quercetin-4′-monoglucoside from the inner scales of the onion (*Allium cepa* L.)[4], difficulty was found in reproducing the melting point of the crystalline material obtained on successive recrystallizations from various solvents. The material was chromatographically homogeneous in all the more commonly employed solvent systems, only phenol and *m*-cresol resolving it completely into two components. The material was therefore purified by chromatography on Whatman 3*MM* paper sheets with 75 per cent (w/v) aqueous phenol as the developing solvent. The contaminant, which had a higher R_F in phenol than quercetin-4′-monoglucoside, crystallized from aqueous ethanol as fine yellow needles with melting point 259–261°.

Trypsin Inhibitor in Wholewheat Flour

PRELIMINARY work on a trypsin inhibitor in wholewheat flour was reported by Shyamala[1]. A crude concentrate containing the trypsin inhibitor was prepared by the 'ammonium sulphate' method of Borchers *et al.*[2] modified by Lyman[3] as follows:

(1) A homogenate of the wholewheat flour was prepared by mixing the flour with ten volumes of water in a blender. The *p*H was adjusted to 4·2 with acid and the mixture was allowed to stand overnight.

(2) The 'ammonium sulphate precipitate' was obtained by adding ammonium sulphate, 30 per cent of the volume of the extract. The precipitate containing the inhibitor was re-precipitated with ammonium sulphate. The material obtained was dialysed overnight and then lyophilized. Approximately 3 gm. of material was obtained from 300 gm. of flour.

The activity of trypsin was determined by the method of Anson[4] using the modification of Orringer *et al.*[5]. The degree of colour produced by the phenol reagent indicated the relative proteolytic activity of the trypsin. For testing the activity of the inhibitor, it was added to the enzyme at several concentrations and the degree of proteolytic activity inhibited was estimated. A logarithmic plot of this inhibition gave a straight line from which the point of 50 per cent inhibition could be readily obtained.

Crude material (6·5 mgm.) prepared as described here was needed for 50 per cent inhibition of the activity of trypsin while 55γ of a crude concentrate of soybean trypsin inhibitor prepared by the same method was needed for 50 per cent inhibition. The activity was lost when the preparation was heated in a boiling water bath for 20 min.

Table 1. TRYPSIN-INHIBITING ACTIVITY OF THE INHIBITORS FROM WHOLEWHEAT FLOUR AND SOYBEAN

Ammonium sulphate precipitation				Trichloroacetic acid	
Soybean inhibitor (γ)	Optical density at 765μ	Wholewheat inhibitor (mgm.)	Optical density at 765μ	Wholewheat inhibitor (mgm.)	Optical density at 765μ
0	0·480	0	0·470	0	0·480
13	0·412	1·0	0·440	1·0	0·395
26	0·355	2·5	0·375	2·0	0·320
52	0·270	5·0	0·285	3·0	0·270
78	0·180	10·0	0·170	5·0	0·172
50 per cent inhibition at 55γ.		50 per cent inhibition at 6·5 mgm.		50 per cent inhibition at 3·5 mgm.	

The crude concentrate prepared as described was used as the starting material for the extraction of the inhibitor with trichloroacetic acid by the method of Kalser and Grossman[6]. The inhibitor appeared in the trichloroacetic acid filtrate while the precipitate had no inhibitor in detectable amounts. The trichloroacetic acid filtrate was dialysed and lyophilized. 3·5 mgm. of this material was needed for 50 per cent inhibition. The appearance of the inhibitor in the trichloroacetic acid filtrate indicates a possible similarity in its behaviour to the pancreatic juice trypsin inhibitor. Further attempts to purify the material are under way.

Recently, Learmonth and Wood[7] reported the presence of a trypsin inhibitor in wheat flour using different assaying techniques.

PHYSIOLOGY

Prevention of Freezing Damage to Living Cells by Pyridine *N*-Oxide

PYRIDINE, like dimethyl sulphide, forms a high-boiling, water-soluble oxide, pyridine *N*-oxide (PNO). It was surmised that PNO might protect living cells against freezing damage in the same way as dimethyl sulphoxide[1] and some other aliphatic compounds[2]. The particular interest attached to PNO is that it would be the first aromatic compound to be used in this connexion.

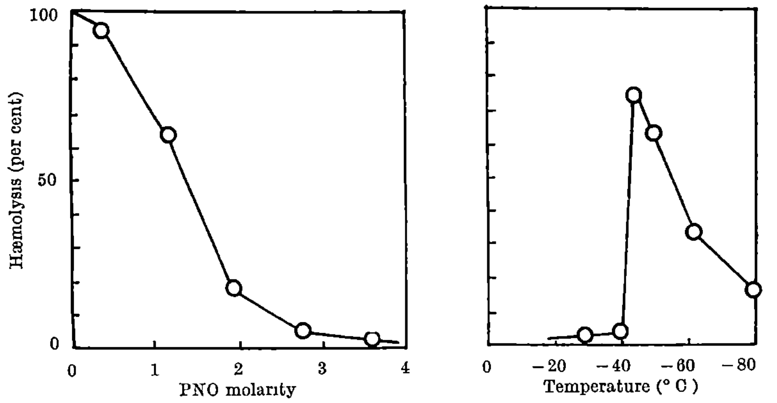

Fig 1 Hæmolysis of red cells suspended in a solution of pyridine N-oxide (PNO) and frozen for 15 min , as a function of PNO concentration at -40° (left), as a function of temperature with 3 2 M PNO (right)

Washed human red blood cells were suspended in buffered saline containing different amounts of PNO and frozen for 15 min at various temperatures between - 20° and - 80° C They were then thawed and spun down, and the amount of hæmolysis estimated colorimetrically in the supernatant Some of the results are shown in Fig 1, hæmolysis being expressed as a percentage of that found in controls without PNO, at each temperature

The sharp rise in hæmolysis at - 40°, and slower fall, recalls the behaviour of acetamide at - 51°, and is probably due to a rise in solute concentration to a toxic level[2] The protective effect is known to depend on permeation of the cells by the solute, and possibly more important than the limited protection found is the fact that PNO is both penetrating and physically non-toxic up to high concentrations On intraperitoneal injection into mice, PNO had a delayed toxicity (LD_{50} 1 5 gm /kgm) rather less than that of pyridine[3], to which it is probably reduced *in vivo* (could be smelt in the viscera) The high solubility of PNO in water is believed to be due to localization and enhancement of the three lone-pairs of electrons on the oxygen, by mesomerism with the aromatic ring It is hoped to discuss the structure of such highly soluble compounds in a later communication

I am indebted to Mr M J Ashwood-Smith for carrying out the toxicity experiments

Influence of Anaerobic Glycolysis on Release of Histamine in the Guinea Pig and Rat Anaphylactic Reaction *in vitro*

An increase of oxygen uptake has been observed during the anaphylactic reaction *in vitro*[1], and it has been shown that anaphylactic release of histamine is inhibited by lack of oxygen[2-4] It has also been shown that the anaphylactic reaction is inhibited by uncouplers of the oxidative phosphorylation[5] It would be expected that the energy-rich compounds formed during the glycolytic cycle would be available for release of histamine, as are those generated in aerobiosis The present investigation was undertaken in order to see if the anaphylactic reaction depends on oxidative metabolism, or if it could also proceed in the presence of an anaerobic metabolism The experiments were carried out with both guinea pig and rat tissues, in order to verify any possible difference in their behaviour, since it has recently been suggested that anaphylactic reaction in rat tissues is not affected by lack of oxygen[6,7]

Sensitized guinea pig and rat lung-slices were incubated in Ringer-phosphate or Ringer-bicarbonate medium with or without glucose, in nitrogen or oxygen atmosphere, in Warburg flasks in which release of histamine was determined by the addition of antigen from the side arm Nitrogen was purified by passing it through melted phosphorus, and its purity verified in an Orsat apparatus[4] Rats were sensitized with horse serum treated by kaolin, according to the method in ref 8 The technique of histamine dosage and other experimental details were as described in ref 5

It has already been shown that a pure nitrogen atmosphere completely inhibits anaphylactic release of histamine in guinea pig lung-slices[4] In the presence of glucose the sensitized guinea pig lung-slices, maintained in anaerobic conditions, showed as would be expected a glycolytic activity, while histamine was released on tipping the antigen Addition to the glucose anaerobic medium of mono-iodoacetate, well known as an inhibitor of the anaerobic glycolysis, completely inhibited this release Table 1 shows the results obtained in typical experiments

Table 1 Effect of Glucose and Mono-iodoacetate on Metabolism and on Antigen Histamine Release from Sensitized Guinea Pig Lung-Slices under Anaerobic Conditions

Experimental conditions		Metabolism		
Atmosphere	Additions	Oxygen uptake Q_{O_2}	Glycolysis Q_{CO_2}	Histamine release (μgm /gm w w)
Nitrogen + 5 per cent carbon dioxide	—		0 85 + 0 09	0 0 ± 0 1
Nitrogen + 5 per cent carbon dioxide	Glucose		5 69 ± 0 34	3 2 ± 0 7
Oxygen	—	5 44 ± 0 30		3 9 ± 0 3
Oxygen	Glucose	5 25 ± 0 36		4 9 ± 0 3
Nitrogen + 5 per cent carbon dioxide	Glucose		6 90 ± 0 54	10 7 ± 0 6
Oxygen	—	5 90 ± 0 40		4 1 ± 0 1
Oxygen	Glucose	6 00 ± 0 19		4 7 ± 0 5
Nitrogen	Glucose	0 11 ± 0 10		5 3 ± 0 5
Nitrogen + 5 per cent carbon dioxide	Glucose		7 98 ± 0 45	17 5 ± 0 4
Nitrogen + 5 per cent carbon dioxide	Glucose + monoiodoacetate, 1 mM		0 45 ± 0 10	0 0 ± 0 1
Nitrogen + 5 per cent carbon dioxide	Glucose		7 06 ± 0 27	11 3 ± 0 4
Nitrogen + 5 per cent carbon dioxide	Glucose + monoiodoacetate, 0 5 mM		0 73 ± 0 09	0 4 ± 0 3

Medium was Ringer-phosphate, or Ringer-bicarbonate when atmosphere contained carbon dioxide Glucose, 0 01 M Spontaneous release of histamine was calculated from these data Each figure is the mean of results from three flasks ± $S E$

In sensitized rat lung-slices, anaerobiosis completely inhibited the histamine released by antigen and small quantities of oxygen were sufficient to remove this inhibition Addition of glucose to the medium also removed the anaerobiosis inhibition (Table 2)

Table 2 EFFECT OF TOTAL AND PARTIAL ANAEROBIOSIS AND OF GLUCOSE IN ANAEROBIC CONDITIONS ON METABOLISM AND ON ANTIGEN HISTAMINE RELEASE FROM SENSITIZED RAT LUNG-SLICES

Experimental conditions		Metabolism		
Atmosphere	Additions	Oxygen uptake Qo_2	Glycolysis Qco_2	Histamine release (μgm/gm w w)
Oxygen	—	7 23 ± 0 35		2 9 ± 0 3
Nitrogen	—	0 65 ± 0 05		0 0 ± 0 0
Oxygen	—	6 34 ± 0 11		2 3 ± 0 3
Nitrogen	—	0 70 ± 0 14		0 0 ± 0 0
Oxygen	—	7 75 ± 0 12		1 4 ± 0 15
Nitrogen + 2 per cent oxygen	—	1 58 ± 0 07		1 0 ± 0 1
Oxygen	—	8 10 ± 0 20		3 9 ± 0 2
Nitrogen + 4 per cent oxygen	—	2 15 ± 0 15		3 6 ± 0 3
Oxygen	—	7 30 ± 0 14		3 5 ± 0 3
Nitrogen + 5 per cent carbon dioxide	Glucose		6 52 ± 0 14	3 5 ± 0 0

Same experimental conditions as in Table 1 Each figure is the mean of results from two flasks ± *S E*

These experiments show that in both guinea pig and rat-sensitized lung-slices the anaphylactic histamine release is not specifically dependent on oxygen This reaction is able to proceed in complete anaerobiosis, if energy is available to the cell, such as that produced by a carbohydrate glycolytic metabolism

Effect of Monovalent Cations on the Blood Pressure of Intact and Hypertensive Rats

WE demonstrated in earlier experiments that it was possible to inhibit renal neurogenic hypertension in rats when potassium salts were mixed with their food[1]. It was likewise demonstrated that the degree of Grollman hypertension did not depend on the absolute quantity of sodium and potassium in the food but on the mutual proportions of the two electrolytes[2] Meneely's experiments[3] gave similar results rats, made hypertensive by excessive doses of sodium chloride, could be kept alive and the rise of their blood pressure stopped by feeding them potassium salts The blood pressure of hypertensive patients can be lowered by a high potassium diet[4]

Excessive consumption of sodium chloride is known to promote hypertension in human beings and animals alike Many workers ascribe this to the higher hydration of the sodium ion which leads to a swelling of the arterial walls[5] According to Pallman[6], an atom of sodium binds 4 3, and an atom of potassium only 0 9 mol of water If the hypertensive effect of sodium and the anti-hypertensive effect of potassium depend on hydration, it would be justified to expect that lithium, as the most hydrated monovalent cation, would produce higher blood pressure than sodium, and that rubidium and cæsium, which are less hydrated, would produce a stronger depressing effect than potassium (An atom of lithium binds 10, that of rubidium 0 5 and cæsium 0 2 mol of water)

In order to test this hypothesis we mixed rubidium and cæsium salts (Rb_2SO_4, CsCl) to the diet of male rats of 150–180 gm body-weight which had been made hypertensive by Grollman's method We also administered lithium salts (LiCl) to such animals since they refused the food which contained lithium it was given by means of intraperitoneal injection The daily doses of rubidium and cæsium were 15 mgm , those of lithium 4 mgm The basal diet contained 26 mgm. of sodium and 61 mgm of potassium per day, while there was 120 mgm. of potassium in the 'high-potassium diet' Figs 1 and 2 illustrate changes in the blood pressure of intact and Grollman-hypertensive animals after administration of different monovalent cations. We determined the blood pressure with our method[7] once a week It can be seen from Fig 1 that the blood pressure of the intact lithium-fed animals already showed an increase during the second week, while the blood pressure measured in rats which had been kept on a high-potassium diet or received rubidium or cæsium did not differ from that of animals kept on a normal diet

By keeping rats, operated by Grollman's method, on a high-potassium diet or by administering rubidium or cæsium to them, it was possible to arrest a further increase in their blood pressure (Fig. 2) Cæsium inhibited the development of hypertension almost completely after a small increase during the first weeks, blood pressure went back in the sixth week to the pre-operative (normal) level

Our experiments allow the conclusion that all monovalent cations are capable of influencing the blood pressure of rats Effect on blood pressure depends on the hydration of the atoms Cations of high hydrating power (lithium, sodium) promote hypertension This property of sodium ions has long been known Lithium has now been proved to be a substance which enables us to produce experimental hypertension in an easy and reliable manner This discovery seems to be of great significance in the field of experimental hypertension since it is now possible to study problems concerning the pathogenesis and treatment of hypertension promptly, without surgical intervention and without the administration of mineralocorticoids (in other words, under compara-

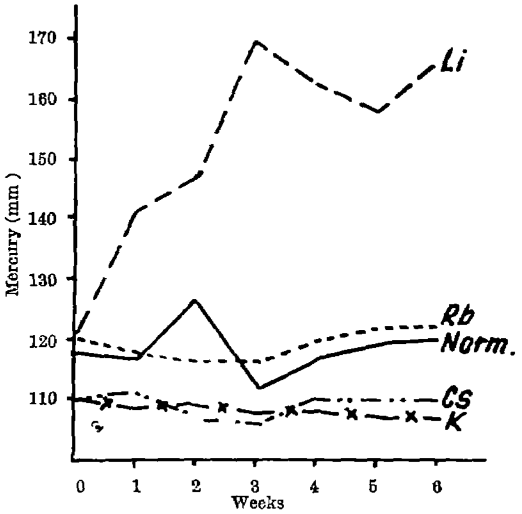

Fig 1 Action of Li, K, Rb and Cs on the blood pressure of intact rats Norm , normal diet, Li, normal diet plus 4 mgm Li, K, normal diet plus 59 mgm K, Rb, normal diet plus 15 mgm Rb, Cs, normal diet plus 15 mgm Cs

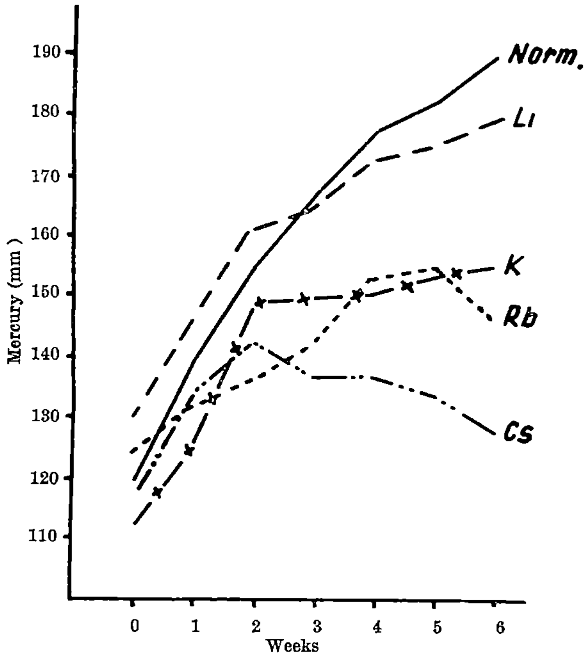

Fig 2 Action of Li, K, Rb and Cs on the blood pressure of Grollman-operated rats (key, see Fig 1)

tively more physiological conditions) The prevention of hypertension by means of rubidium and cæsium also supports (but does not definitely prove) our working hypothesis that the action of monovalent cations on blood pressure, as also the direction of the effect, depends on the degree of ionic hydration

Ambient Temperature and Depot Fat Iodine Number in Children

The degree of unsaturation of depot fat, as measured by its iodine number, has been shown to depend on species, temperature of the environment, diet and site within the body of the fat[1] During the course of investigations in Bantu children aged up to 4 yr in South Africa it was found that as the child got older, so the iodine number of the depot fat (taken from the anterior abdominal wall) increased and the difference between the means of the group under 1 yr old and those aged 1 yr was significant ($P = 0·025 - 0·01$) and between the means of 1 yr and 3 yr. the significance was 1 in 20 Comparison with the 2-yr -old group did not show any significance owing to the small number in the group (Fig 1)

These findings, it is suggested, are consistent with the view that the degree of unsaturation of the depot fat in children is related to the temperature of the environment, as has been shown in animals[2] Of the factors influencing depot fat iodine number the site within the body and species variability need not be considered here The composition of the fat in the diet has been shown to alter the composition of adipose tissue, but relatively large quantities of fat have to be consumed in order to demonstrate this effect[3] These children have no excess of dietary fat, their highest fat intake probably being while breast fed (fat in breast milk = 4 per cent)

Furthermore, the fat consumed by the mother and which is to some extent reflected in the composition of her milk[4] is the same fat as would be consumed by the child when weaned

The difference with age in the South African series could be explained by differences in temperature of the environment to which the child is exposed When this was done the atmospheric temperature varied from 5 to 18° C During early life the child is not exposed to this temperature for long periods of the day as it is carried wrapped in blankets on its mother's back. As it gets older it spends longer intervals of time away from its close contact with the mother and thus the temperature to which the skin is exposed will have lower mean values The iodine number of the depot fat in adult Bantu in South Africa is 67 (ref 5)

In a second series of children in West Africa where the atmospheric temperature was 28–33° C the iodine values showed no rise with age and were similar to those of the 0–1 yr age group in South Africa (Fig 1) The atmospheric temperature in West Africa was therefore close to that which would exist when the child is tied to its mother's back Gradual 'weaning' from the mother's back would not be associated with any marked fall in temperature

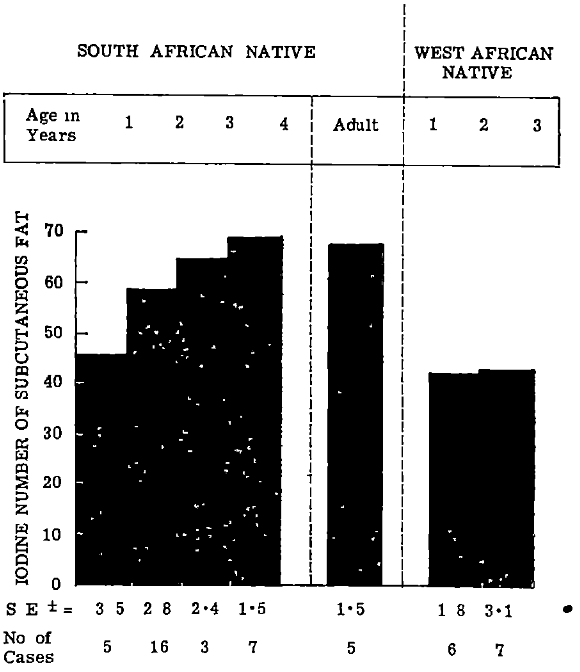

Fig. 1

exposed to the skin, and therefore no striking change in the degree of unsaturation of depot fat, and could account for these older children having the same iodine number as the very young age group in South Africa

It is therefore concluded that these results in children would be consistent with the hypothesis that the iodine number of depot fat is determined, to some extent, by the ambient temperature

Seminal Degeneration induced in Merino Rams by the Administration of Stilbœstrol Dipropionate

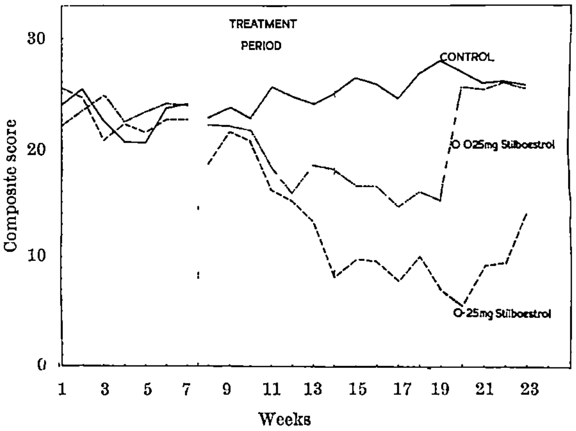
THE statement that rams are unaffected by the ingestion of œstrogenic pasture seems to be based on the failure to detect lowered fertility following mating[1], or metaplastic changes in the bulbo-urethral and prostatic glands of rams from properties where ewes exhibit the syndrome of 'clover infertility'[2,3] Substantiation has been drawn from the protection conferred by the administration of androgens to castrates treated at the same time with stilbœstrol[4] No reports have been noticed of the results of semen examination of rams fed œstrogenic pastures or treated with synthetic œstrogens, although it has been shown that injections of 35 mgm /week of œstradiol benzoate may alter semen characters of bulls in 3 weeks, these returned to normal within 5 weeks of the cessation of treatment[5]

In experiments conducted at the Ian Clunies Ross Laboratory, fifteen Merino rams, aged approximately 24 months, were divided at random within live weight classes into three groups, mean live weights were 45 kgm

Semen samples were collected from each ram by electro-ejaculation[6] at weekly intervals for 23 weeks beginning August 17, 1960 The samples were assessed for volume, sperm density and total sperm numbers, motility and for the percentages of morphologically normal and live sperm After a pre-treatment period of seven weeks, to allow each group to establish reasonably consistent base-lines, treatments were begun These consisted of intra-muscular injections of stilbœstrol dipropionate at daily dose-rates of 0 025 mgm /sheep for group 1 and 0 25 mgm /sheep for group 2 Peanut oil alone was injected into the control group 3 Treatments continued between the eighth and fourteenth weeks inclusive of the experiment, and were then stopped

Sperm motility was scored visually between 0 and 10, and the percentages of live and of normal sperm were converted to a scale of 0–10 by taking each 10 per cent as one point Because of the large variation that occurs in total sperm numbers in semen samples collected by electro - ejaculation (Mattner and Voglmayr, unpublished) this character was disregarded in the composite scores

Mean total scores for each week for each group of rams are shown in Fig 1, which reveals a depression in semen quality as the result of the treatments Group 2, which received 0 25 mgm stilbœstrol, had not completely recovered within 9 weeks of treatment being stopped, but group 1, which received 0 025 mgm stilbœstrol, showed substantial recovery within 6 weeks of treatment ceasing The control group remained unaffected



Of the individual semen characters examined, motility was most adversely affected, and in group 2 this fell to zero by the seventh week after stilbœstrol injections began The mean percentage of live sperm in semen samples from this group fell from 85 per cent before treatment to 40 per cent by the seventh week of treatment, and to 20 per cent by the twentieth week, that is, 6 weeks after treatment ceased The mean total sperm numbers of both groups 1 and 2 began to decline 5 and 7 weeks respectively after treatment commenced Four weeks after these declines became evident, mean total sperm numbers obtained from group 2 at each collection ranged between 100 × 10^6 and 300 × 10^6 and from group 1 between 500 × 10^6 and 1000 × 10^6 No upward trend occurred in group 2 until 9 weeks after treatment ceased, mean sperm numbers for group 1 rose to 2000 × 10^6 within 3 weeks and were maintained at this average until the ninth week after the administration of stilbœstrol stopped Mean total sperm numbers obtained from the control group during the whole of the experiment fluctuated between 4000 × 10^6 and 5000 × 10^6

Rams grazing highly œstrogenic pastures in Australia are unlikely to ingest the equivalent of 0 25 mgm stilbœstrol/day administered to group 2 Dose-rates of 0 03 mgm diethylstilbœstrol/sheep/day for 6 months adversely affected the breeding performance of ewes[7] Preliminary observations (Southcott, Braden and Moule, unpublished) indicate that Merino ewes grazing red clover (*Trifolium pratense*) pastures at Armidale (New South Wales) may have an œstrogen intake equivalent to 0 015 mgm stilbœstrol dipropionate/day, but bio-assay of collected subterranean clover (*Trifolium subterraneum*) fed to castrated guinea pigs has shown far higher œstrogenic equivalents[4] It is clear that the dose-rate of œstradiol benzoate/kgm live weight required to produce seminal degeneration in bulls[5] could be as much as twenty times the dose of stilbœstrol dipropionate/kgm live weight required to affect the semen of rams, thus it is unlikely that bulls could consume sufficient œstrogenic pasture to affect spermatogenesis The evidence available indicates that cattle are unaffected by grazing pastures that severely affect sheep[1]

It should not necessarily be concluded that grazing pasture possessed of high œstrogen equivalencies will induce seminal degeneration in rams. So far the activity of pasture in terms of stilbœstrol dipropionate has been estimated by the use of castrated male sheep and spayed ewes allowed to graze the pasture under test. On assimilation by the entire male, the isoflavones formononetin, genistein and biochanin A, and diadzein and the lactone coumestrol may not lead to the formation of substances likely to impair spermatogenesis. Furthermore, this experiment was conducted at a time of the year when the androgen output by the rams may have been low.

PHARMACOLOGY

Repetitive After-discharge produced by Drugs in Nerves treated with Cetyltrimethylammonium Bromide

A WELL-ESTABLISHED pharmacological property of tetraethylammonium ion (TEA) is the production of repetitive nerve action potentials in response to single stimuli[1]. We have recently been examining the relationship between quaternary ammonium ion structure and this type of activity. After several experiments, however, it became apparent that the effects of TEA and other ethonium ions were not reproducible except at very high concentrations of 30 m*M* or more. Accordingly, we resorted to testing these drugs on nerves treated with the cationic detergent, cetyltrimethylammonium bromide (CTMB). Certain methonium ions which normally have little or no effect on nerve produce conduction block after CTMB treatment[2,3]. The experiments described here reveal that CTMB also increases the capacity of ethonium ions to produce repetitive firing.

All experiments were done on sciatic nerves isolated from cold-adapted winter and spring frogs (*Rana pipiens*). Except for brief stimulating and recording intervals in air, the nerves were bathed in a buffered frog Ringer solution (*p*H 7·2) at a temperature of 16–18° C. Monophasic action potentials were recorded with differential amplification, displayed on an oscilloscope, and photographed. A square-wave stimulus of 0·1 m.sec. duration was applied every 2 sec. Stimulus intensity was supramaximal for the rapidly conducting *A* fibre group. The nerve chamber contained a small centre well located between the platinum stimulating and recording electrodes. Drugs and CTMB were added to the Ringer solution in this centre well only. The so-called treated segment of the nerve was initially bathed in CTMB–Ringer for 60 min., then in CTMB–Ringer–drug solution. CTMB concentration was kept at 1 μgm./ml.

The compounds used in these experiments were TEA chloride, phenyltriethylammonium iodide and 3-OH phenyltriethylammonium iodide. With the appropriate concentration of each compound, two effects were consistently observed: (1) an increase in amplitude and time-course of the negative after-potential; (2) repetitive after-discharge. Summation of asynchronous and low-amplitude repetitive spikes of many individual axons prevents accurate measurement of the negative after-potential. Therefore, only the repetitive firing was used as an indicator of drug action, and this response was treated as a graded one. The frequency, number and amplitudes of repetitive spikes were concentration and time dependent.

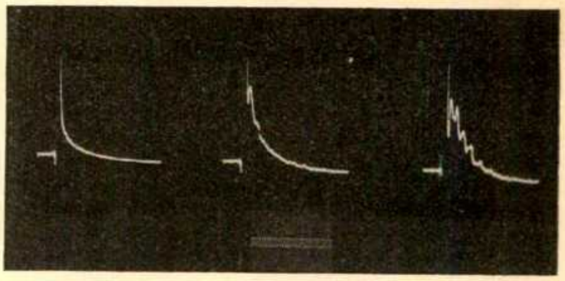

Fig. 1. Repetitive after-discharge produced by 5 μgm./ml. phenyltriethylammonium ion in presence of CTMB. Left, control record taken after 30 min. in Ringer; middle, threshold response obtained after 5 min. in CTMB–Ringer–drug solution; right, maximal response obtained after 30 min. in CTMB–Ringer-drug solution. Time line, 1,000 cycles/sec.

The approximate concentration of each ethonium ion required for a minimal response was determined on at least 4 normal and 4 CTMB-treated nerves. A typical response is illustrated in Fig. 1. For each ion, CTMB markedly lowered the approximate concentration required for threshold response (Table 1). The time between drug application and onset of effect was not altered by CTMB when using threshold concentrations; but when the threshold concentration as determined on a normal nerve was applied to a CTMB-treated nerve, the latent period was too short to measure. Our results might have been even more striking had we used a higher CTMB concentration. However, we wished to avoid the direct actions of CTMB on ion permeability which were recently observed in the giant axon of the squid[4].

Table 1. COMPARISON OF DRUG-INDUCED REPETITION IN NORMAL AND CTMB-TREATED NERVES

Drug	Normal nerves Threshold concentration* (m*M*)	Normal nerves Time to onset† (min.)	CTMB-treated nerves Threshold concentration* (m*M*)	CTMB-treated nerves Time to onset† (min.)
Tetraethylammonium	10–20	20	0·5–2	45
Phenyltriethylammonium	20–30	30	3–5	30
3-OH phenyltriethylammonium	30–40	10	3–10	13

* Range of approximate threshold concentrations on 4–7 nerves.
† Average of results obtained on 4–7 nerves.

Koketsu's experiments[5] indicated that TEA prolongs the negative after-potential in frog motor nerve terminals. The concentrations used by Koketsu approximated those needed in the present work to produce repetitive firing of CTMB-treated axons. The unmyelinated axon terminals are more sensitive than the rest of the axon to TEA, probably because the latter possesses a permeability barrier which impedes the access of quaternary ammonium ions to their sites of action. It is this barrier which a cationic detergent like CTMB appears to remove.

This investigation was supported by U.S. Public Health Service grant *B*–2605, National Institute of Neurological Diseases and Blindness.

Cholinergic Transmission Mechanisms for both Excitation and Inhibition in Molluscan Central Synapses

WE have previously reported[1] that the application of acetylcholine by perfusion or local injection to different central neurones of the mollusc *Aplysia depilans*, impaled with intracellular microelectrodes, always produced one of the two following reactions: (*a*) cells of one type, conventionally designated by us as *H*-neurones, are hyperpolarized and inhibited by the drug (Fig. 1, *H*1), and (*b*) cells of another type, or *D*-neurones, are depolarized and excited (Fig. 1, *D*1).

Further microphysiological analysis revealed that *H*-neurones receive both excitatory and inhibitory inputs, but that *D*-cells receive only excitatory input. A pharmacological investigation enabled us to demonstrate that acetylcholine fulfils almost all the requirements necessary in order that it be accepted as the chemical transmitter of synaptic inhibition in *H*-neurones[1,2].

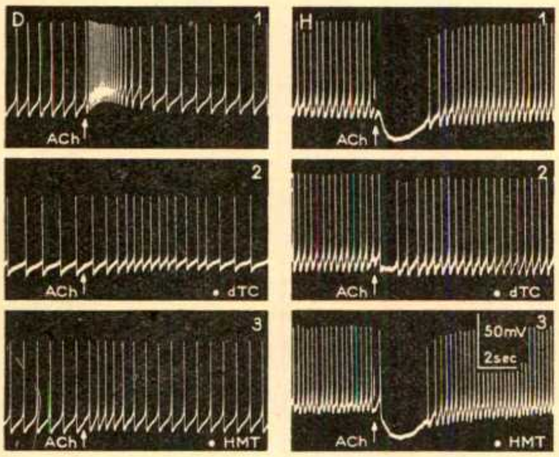

Fig. 1. (1) Effect of brief electrophoretical injections of acetylcholine (arrows) on the somatic membrane of a *D*-cell (left column) and an *H*-cell (right column) firing spontaneously. The drug depolarizes the *D*-cell and accelerates its firing, while it hyperpolarizes the *H*-cell and inhibits firing.
(2) Same amount of acetylcholine as in (1) is injected on the *D*-cell (left) and the *H*-cell (right) but in the presence, in the bathing fluid, of 10^{-4} gm./ml. of *d*-tubocurarine, which clearly inactivates both *D*- and *H*-cell membranes to the action of acetylcholine.
(3) The same electrophoretical injection of acetylcholine on *D*- and *H*-cells, as in (1), but in the presence, in the bathing medium, of 10^{-4} gm./ml. of hexamethonium bromide. This latter drug inactivates the *D*-cell membrane to the action of acetylcholine (left) but has no effect on the response of the *H*-cell membrane to acetylcholine

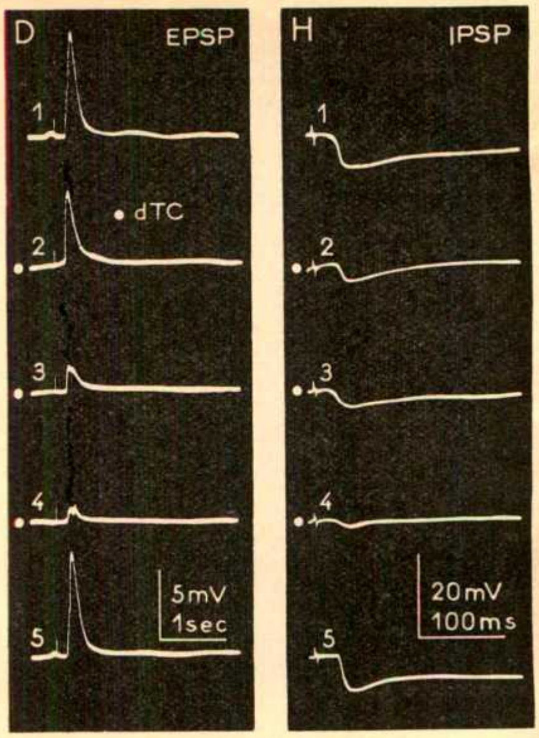

Fig. 2. Effects of *d*-tubocurarine in 10^{-4} gm./ml. concentration (white dots, 2–4) on the evoked excitatory postsynaptic potential in a *D*-cell (left column) and on the inhibitory postsynaptic potentials in an *H*-cell (right column). The synaptic potential in the *D*-cell is composed of two elementary excitatory synaptic potentials. In both cells the drug inactivates the postsynaptic membrane to natural excitatory and inhibitory transmitters respectively, as indicated by the gradual diminution (2–4) of the postsynaptic potentials. The removal of the curare restores the initial amplitude of the synaptic potentials (5)

Recent experiments brought out the surprising result that acetylcholine may also very likely be considered as the chemical transmitter for synaptic excitation in *D*-neurones. These neurones are highly sensitive to the drug; threshold effects on the cell excitability were observed with concentrations of less than 10^{-10} gm./ml. in absence of any anticholinesterase. Applied either by perfusion or locally injected, acetylcholine produces a spectacular drop in the *D*-cell membrane impedance, as in the neuromuscular end-plate of vertebrates[3] and the Purkinje fibres of vertebrate heart[4], where its transmitter action is well proved. Detectable increases of membrane conductance were observed for concentrations of acetylcholine down to 10^{-8} gm./ml. with a square pulse technique permitting the detection of impedance variations as small as 2–3 per cent.

Electrophoretical injections of acetylcholine on the *D*-cell membrane, following the technique of del Castillo and Katz[5], resemble the excitatory synaptic action (Fig. 1, *D*1). Like that of the excitatory synaptic potential, the equilibrium potential-level of this action is closer to the zero potential than the resting potential; if the membrane potential is artificially increased, the amplitude of both excitatory postsynaptic potential and depolarization produced by acetylcholine increases. The effects of electrophoretical injections of acetylcholine on the *D*-cell membrane (as well on the *H*-cell membrane) are diminished or abolished in the presence of a solution 10^{-4} gm./ml. of *d*-tubocurarine (Fig. 1, *D*2 and *H*2) or atropine. This block may probably be attributed to the inactivating effects caused by these drugs on the cell membrane cholinergic receptors It is highly significant that, in the presence of *d*-tubocurarine or atropine, the excitatory postsynaptic potentials in *D*-cells (and the inhibitory postsynaptic potentials in *H*-cells) also show rapid diminution of their amplitude or even disappear (Fig 2, *D* and *H*) This inactivating effect of curare and curare-like drugs on synapses constitutes an important argument in favour of the cholinergic nature of the synapses[6,7]

The action of hexamethonium was very remarkable (Fig 1, *D*3 and *H*3) In the presence of this drug, the *D*-cell membrane is inactivated to the action of the injected acetylcholine, whereas the *H*-neurone membrane is not affected and shows a normal hyperpolarizing response to acetylcholine Likewise, hexamethonium greatly diminishes the amplitude of the excitatory postsynaptic potentials in the *D*-neurones, but has no effect on the inhibitory postsynaptic potentials in *H*-cells This behaviour illustrates once more the pharmacological specificities of the *D*- and *H*-cell membranes, seen also with several other drugs[8]

The foregoing arguments seem to us to be a rather strong indication in favour of the cholinergic nature of the excitatory synaptic input in *D*-cells, especially if we remember that acetylcholine is normally present in *Aplysia* nervous system[9] and that a specific cholinesterase was demonstrated by both biochemical[10] and physiological[2] methods As in *H*-neurones, the extrasynaptic membrane of the cell body is highly sensitive to the natural transmitter

Recalling that the synaptic excitatory input of *H*-neurones is not at all affected by drugs which block cholinergic transmission[2], we presume that the excitatory synaptic input is conveyed by an unknown transmitter other than acetylcholine

Fig 3 illustrates the nature of the synaptic inputs on *D*- and *H*-cells. As the excitatory synaptic transmission in *D*-cells and the inhibitory one in *H*-cells appear to be cholinergic, the existence of interneurones capable of excitatory action through some of their synaptic endings and inhibitory actions through others at the same time is likely (dotted lines in Fig 3) This dual cholinergic mechanism emphasizes the importance of the postsynaptic membrane for the character of the transmission, the same transmitter in the same ganglion being able to produce opposite synaptic actions

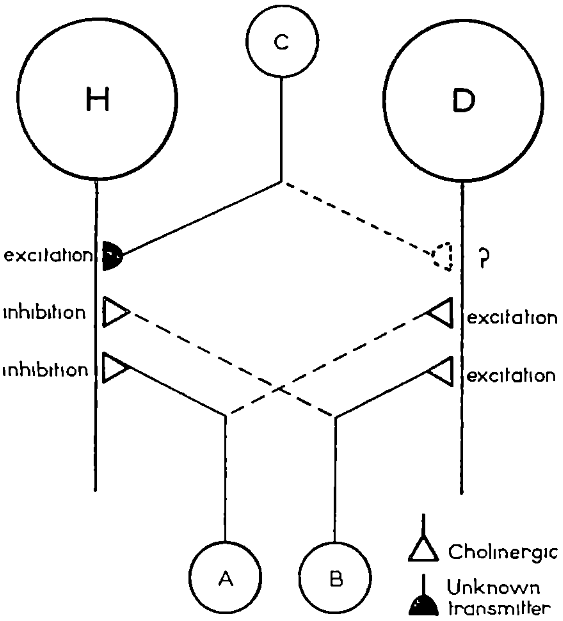

Fig 3 Diagram illustrating the nature of synaptic contacts on the *H*- and *D*-cells The inhibitory input to the *H*-neurone and the excitatory one to the *D*-cell are cholinergic A probable contact of a single presynaptic neurone (either *A* or *B*) with both *H*- and *D*-cells is indicated by the dotted lines The excitatory input on the *H*-cell is conveyed by an unknown transmitter different from acetylcholine A possibility of contact between the presynaptic cell *C* and the postsynaptic *D*-neurone is marked with a dotted line, no evidence exists concerning the effect of the unknown transmitter on the *D*-neurone

Conclusions from the above results may be summarized as follows (1) As was demonstrated elsewhere[1,2], acetylcholine, by its effects on *Aplysia depilans* neurones, enables one to distinguish two types of cells *D*-cells, depolarized and excited by the drug, and *H*-cells, hyperpolarized and inhibited The *D*-neurones only show excitatory synaptic input, whereas *H*-neurones present both excitatory and inhibitory synaptic input (2) In *D*-neurones, the synaptic excitatory input may be considered as cholinergic (3) In *H*-neurones, inhibitory input is also very likely cholinergic, but the excitatory input in these cells appears to depend on another, unknown chemical transmitter Hence, the character of synaptic transmission, excitatory in *D*-cells and inhibitory in *H*-cells, does not depend solely on the nature of the chemical transmitter—acetylcholine in both cases—but on physicochemical differences in the postsynaptic membrane that react in a specific way to the transmitter (4) Existence of interneurones which would simultaneously induce excitatory and inhibitory synaptic actions in different postsynaptic neurones is a real possibility

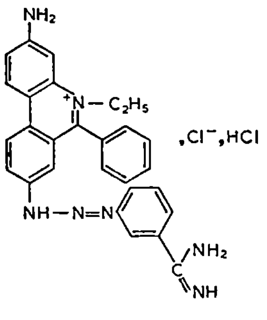
CHEMOTHERAPY

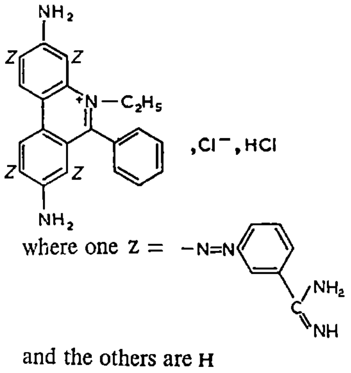
A New Prophylactic Trypanocidal Drug, 2,7-di-(*m*-amidinophenyldiazoamino)-10-ethyl-9-phenyl-phenanthridinium Chloride Dihydrochloride (*M & B* 4596)

THE properties of the trypanocidal drugs obtained from the coupling reaction of *m*-amidinobenzenediazonium chloride and homidium chloride have been described by Wragg, Washbourn, Brown and Hill[1], and Berg[2]. Metamidium was the mixture of the red (I) and purple (II) isomers (45 and 55 per cent respectively), and isometamidium was the pure red isomer (I)

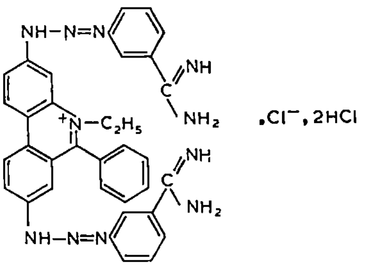
In the study of the structure–activity relationships among this series of compounds, many similar coupling reactions have been investigated. In an attempt to prepare the 2,7-di-*m*-amidinophenyl-



(I)



(II)



(III)

diazoamino derivative (III) of homidium, the coupling reaction of 2 mol. of *m*-amidinobenzenediazonium chloride and 1 mol. of homidium chloride was examined. Only (I) and (II) were present in the reaction product and none of the desired *bis*-compound (III) was obtained. The latter compound, however, was readily prepared by the coupling reaction of tetrazotized homidium chloride (1 mol.) and *m*-aminobenzamidine monohydrochloride (2 mol.). It separated from the reaction mixture as a brown granular solid, which was washed with aqueous sodium chloride and dried at room temperature. It usually contained approximately 10 per cent of sodium chloride and was submitted for biological examination without further purification as *M & B* 4596. It decomposed at 245°, and was approximately 1.5 per cent w/v soluble in water; the *p*H of a 1 per cent w/v solution being 4.7 at 20°. It could be stored in the solid state for at least two years without significant decomposition, but it began to lose nitrogen when heated above 70°. Aqueous solutions lost nitrogen when warmed above 40°. On heating (III) with cuprous chloride and 3 *N* hydrochloric acid for 7–10 min. the theoretical amount of nitrogen was evolved.

Table 1. TOXICITY AND THERAPEUTIC ACTIVITY AGAINST A LABORATORY STRAIN OF *T. congolense* IN MICE

Compound	*LD*50 (mgm./kgm.) subcutaneous	*CD*50 (mgm./kgm.) by subcutaneous injection
Homidium	75	0.03
Metamidium	210	0.0075
Isometamidium	260	0.002
M & B 4596	> 1,000	0.6

Table 2. PROPHYLACTIC ACTIVITY OF *M & B* 4596 AGAINST A LABORATORY STRAIN OF *T. congolense* IN DIRECT COMPARISON WITH METAMIDIUM CHLORIDE

Compound	Dose (mgm./kgm.) subcutaneously	No. of mice protected/No. treated Weeks after dosing 2	3	4	6	9	12	16	20	24
● Metamidium chloride	25		6/6		5/5	6/6	11/11	10/10	11/14	8/10
	5			4/4		4/6				
	1	6/6		19/19	9/14					
M & B 4596	25		6/6		5/5	6/6	20/20	19/21	15/15	10/10
	5			4/5		4/4				
	1	5/6		11/19	9/16					

The therapeutic and prophylactic activity of the compound against a laboratory strain of *Trypanosoma congolense* was determined by the methods described by Wragg *et al.*[1], and the results are summarized in Tables 1 and 2. The compounds were all examined as their chloride hydrochlorides, and the doses are given as weight of total salt.

Although *M & B* 4596 was much less active therapeutically than metamidium, it was no less active prophylactically. The local reactions produced by the subcutaneous injection of 10 per cent w/v aqueous suspensions of *M & B* 4596 into calves compared favourably with those caused by metamidium chloride and metamidium suraminate.

The prophylactic activity of *M & B* 4596 against *T. congolense* has been confirmed in cattle, and results of field-trials in Africa are very encouraging. The compound has also been presented for examination as its 12 per cent w/v water-soluble methane sulphonate (*M & B* 4596*B*), and its sparingly water-soluble β-naphthalene sulphonate (*M & B* 4596*A*).

We thank Dr. H. J. Barber, Dr. R. Wien and Dr. J. N. Ashley for their interest, and Mr. J. M. S. Lucas for the local tolerance studies.

ANATOMY

Staining Properties of Stressed Bone

THE recent communication by Prof. C. J. Dreyer[1] on this topic is of great interest in relation to the general matter of the staining reactions of (presumably) collagen fibres. The change in staining reaction from green to reddish-brown with a corresponding change from optical isotropy to anisotropy, in unstressed and stressed bone, respectively, accord well with what has been observed in this Department in work on developing collagenous tissues. Using the Falg technique[2,3], it has been found that there are three stages in the development of this tissue which may be called the initial, the semi-mature and the mature. These three stages are distinguishable with the greatest constancy by the readiness with which they accept acid fuchsin, that is, by what has been earlier termed their erythrophilia. In the initial stage, presumptive collagen fibres are weakly erythrophile, in the semi-mature stage they are moderately erythrophile, and in the mature stage they are strongly erythrophile. The Falg technique, as well as others based on a similar chemical process, enables the consequent differences in monochromatic coloration (amplitude) to be converted into corresponding differences in colour (wave-length). Weakly erythrophile elements (of any kind) are coloured blue, the moderately erythrophile are coloured violet and the strongly erythrophile are coloured a deep red. In these reactions the acid fuchsin, which is an amphoteric and not an acid dye, behaves as an acid towards the basic elements of the tissues stained by it. Other acid dyes, for example, light green yellowish *SF* in the Falg technique, attach themselves to the acid fuchsin basic side-chains in a manner discussed in the papers cited.

The Masson stain used by Dreyer is a very complex staining mixture, for it includes not only acid fuchsin and aniline blue (an acid triphenylmethane behaving like the other acid triphenylmethane, light green) but also hæmatoxylin. Recent work in this Department shows that hæmatoxylin will attach itself to free acid groups of the acid dye which has attached itself to acid fuchsin as mentioned above. Nevertheless, in all cases mature collagen fibres retain the red colour. Accompanying the increased erythrophilia of developing collagenous tissues there is a corresponding increasing birefringence, particularly well shown by the compound polarizer, the principles of which have already been stated in *Nature*[4].

It would appear then that Prof. Dreyer's results are explainable as a demonstration of a special maturation of collagen fibres in those regions of stressed bone which he has studied. This is in accord with the general principle that collagen fibres are to tension fields as iron filings are to magnetic fields[5], a principle well established both by gross and microscopic anatomy on one hand and experiment on the other.

PATHOLOGY

Experimental Atheroma in Budgerigars

Since Anitschkow and Chalatow[1] in 1913 first induced lesions simulating human atherosclerosis in rabbits by feeding a diet rich in cholesterol, many workers have used rodents for this purpose despite the fact that spontaneous atheroma, apart from microscopic lesions, rarely develops in these mammals. Experimental atheroma has been produced by various dietetic alterations in other animals, including monkeys[2,3], pigs[4], chickens[5,6] and geese[7], but the parrot family (Psittacidae) have rarely been used although the more aged, captive birds in this order develop spontaneous atheromatous-like arterial lesions of an intensity usually seen only in man[8,9]. This communication describes cholesterol atheromatosis induced in budgerigars (*Melopsittacus undulatus*), which are the least expensive and most easily reared and housed of the psittacines.

Twenty-eight adult female budgerigars, reputably aged between 2 and 5 years, were divided into four equal groups. Group 1, used as controls, were fed a diet of 60 per cent millet and canary seed and 40 per cent pin-head oatmeal. Group 2 received 60 per cent seed, 38 per cent oatmeal and 2 per cent cholesterol. Group 3 received 60 per cent seed, 23 per cent oatmeal, 2 per cent cholesterol and 15 per cent Danish lard. Group 4 were fed a diet of 60 per cent seed, 25 per cent oatmeal and 15 per cent Danish lard. Food, water and grit were available *ad libitum*. One bird in each group was killed at 30-day intervals over a period of six months. Three birds died during the experimental period. Tissues were examined by naked-eye and histologically, and in order to facilitate recognition of small lipid deposits in the gross aorta and brachio-cephalic arteries the opened vessels were treated with sudan IV.

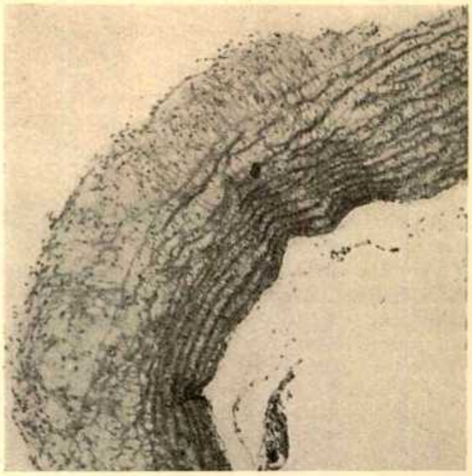

Fig. 1. Atheromatous plaque containing numerous foamy, lipid-laden histiocytes in aorta of a budgerigar fed on a diet containing cholesterol and lard for 4 months. Due to inversion the vessel lumen is at top left. Hæmatoxylin and eosin staining. (× 65)

Birds in groups 2 and 3 showed slight, sudanophilic lipid stippling of the inner walls of the aorta and brachiocephalic arteries after receiving their respective diets for two months. After three months, multiple, creamy white or yellow, lipid-containing nodules and plaques had formed in the intima and inner media of the arteries (Fig. 1). These lesions were more marked and more extensive at the end of the present experimental period of six months. Sub-endothelial accumulations of lipid narrowed several of the small coronary vessels (Fig. 2) and, in two instances, related small areas of myocardial infarction were seen. Vascular thrombosis was not observed. Blood cholesterol-levels were raised in all birds of groups 2 and 3; concentrations being greater than 300 mgm. per ml. as compared with cholesterol-levels

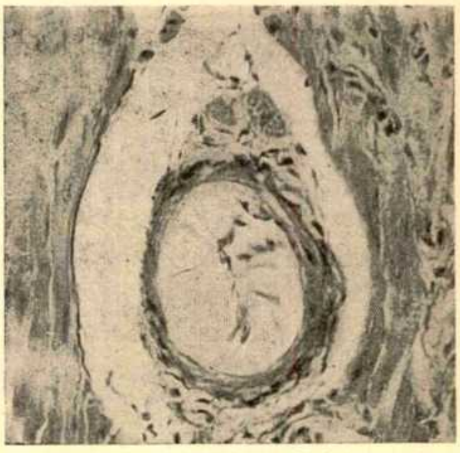

Fig. 2. Sub-endothelial lipid in small, intramural coronary vessel. Lumen distorted and narrowed. Weigert's elastic and van Gieson's stain. (× 300)

ranging from 150 to 200 mgm. per 100 ml. in group 1 (control) birds. The vascular changes were slightly more marked in group 3 as compared with group 2, but considering the small number of animals used this may well have been due to chance. No vascular lesions were observed in birds of group 1 and group 4, except for some light sudanophilic speckling of the thoracic aorta and brachio-cephalic trunks, associated histologically with small, focal lipid deposits in the non-muscular laminæ of the inner media of the arteries, of one bird in group 1.

The livers of birds in groups 2 and 3 were enlarged, pale and fatty. Initially the lipid infiltration was diffuse and largely within the cytoplasm of parenchymal hepatic cells; later the lipids accumulated more focally and appeared to be mainly within the cytoplasm of histiocytes. Lipid-laden histiocytes were seen also in the spleen, kidneys and ovaries. Birds in group 4 showed moderate fatty changes in the liver during the first three months of the experimental period. The liver and other viscera of birds in group 1 were normal.

Although experimentation has been limited, it would appear that diets containing added 2 per cent cholesterol or 2 per cent cholesterol and 15 per cent animal fat in the form of lard are highly atherogenic to young, adult female budgerigars, whereas a diet supplemented only by 15 per cent lard does not produce vascular lesions. Further work on naturally occurring and experimental atheroma in psittacines is being undertaken. While the pig is probably the most satisfactory animal for studies on atherosclerosis, it is suggested that the budgerigar may be of value where space and money are restricted.

One of us (R. F.) is indebted to Eli Lilly and Co., Ltd., for financial support. We thank Prof. J. W. S. Blacklock for advice; Mr. J. W. Miller, St. Bartholomew's Hospital, for technical assistance, and Mr. P. R. Crocker for photomicrography.

Orosomucoid in Schizophrenia

Orosomucoid, a glycoprotein extremely rich in carbohydrate, is the principal constituent of the perchloric acid-soluble seromucoid fraction of human serum[1]. In contrast to the seromucoid fraction which contains several proteins and represents more than one biological entity, orosomucoid is homogeneous and behaves as a single protein. With the production of specific chicken antiorosomucoid sera[2,3], it has become possible to investigate the clinical significance of orosomucoid. Interest in doing so arises from the fact that elevations of seromucoid and total serum glycoprotein-levels occur in a number of diseases; for example, in malignancy, tuberculosis, rheumatoid arthritis, and multiple sclerosis[4]. Elevations in this chemically defined group of proteins also occur in response to a wide range of non-specific stressors such as fractures, epinephrine injection, and burns[5].

Serum-levels of orosomucoid have now been measured immunochemically[2,3] in a large number of cancer patients and to a smaller extent in patients with other organic pathologies. Quite marked elevations of the protein have been observed, particularly in advanced malignancy[3], suggesting that processes destructive of tissue play a key part in increasing its serum concentration. However, such processes may merely serve as non-specific stressors which then act through systemic mechanisms to increase the serum concentration of orosomucoid. This communication concerns orosomucoid in schizophrenia, a disease in which tissue pathologies have never been demonstrated.

Comparisons were made between 41 non-psychotic control subjects (laboratory personnel) and 40 schizophrenic patients with respect to serum-levels of orosomucoid and albumin. These proteins were determined as in refs. 3 and 6, involving the precipitin reactions of specific chicken antisera. In previous work with cancer and tuberculosis sera, it was observed that when the orosomucoid concentration was markedly elevated, the albumin concentration was depressed. Thus the ratio of orosomucoid to albumin seemed to provide an even more sensitive indication of a pathological process than the orosomucoid-level alone. It was for this reason that both orosomucoid and albumin were measured in the controls and schizophrenics and that the orosomucoid : albumin ratio was computed for each subject.

Both the control and patient groups were off drugs and were free of physical disease so far as could be determined by physical examination, chest X-ray, routine complete blood count, and urinalysis. All the patients had been in hospital with schizophrenia for more than 4 years. Two-thirds of the group were under careful dietary supervision in a metabolic ward at the Lafayette Clinic, while the remaining third came from Pontiac State Hospital. The data for these two patient groups were combined, since there were no significant differences between them in the variables under investigation.

Table 1. COMPARISON OF ALBUMIN- AND OROSOMUCOID-LEVELS IN SCHIZOPHRENIC AND CONTROL GROUPS

	Control group ($N = 41$)		Schizophrenic group ($N = 40$)			
	Mean	*S.D.*	Mean	*S.D.*	t	P
Albumin	48·3	3·4	45·7	4·5	2·90	< 0·01
Orosomucoid	0·842	0·185	1·005	0·196	3·81	< 0·001
Ratio of orosomucoid to albumin	0·0175	0·0041	0·0223	0·0055	4·34	< 0·001

The mean albumin (Table 1) was significantly lower for the schizophrenic group than for the control subjects ($P < 0·01$). In contrast, the mean orosomucoid was significantly higher for the schizophrenic subjects ($P < 0·001$). The difference between the two groups was also evident when the orosomucoid/albumin ratios were compared: 0·0223 in the schizophrenic group against 0·0175 in the control group.

These findings are of interest in two ways: (*a*) they suggest that orosomucoid may be a reactor to a variety of non-specific stressors not necessarily associated with tissue destruction or proliferation, and (*b*) they indicate that other than purely psychological factors appear in the chronic schizophrenic illness and that either primary or secondary metabolic changes have occurred In this connexion the hypothesis that schizophrenic patients are in a chronically stressed state would seem to be supported

RADIOBIOLOGY

Activity of Deoxyribonuclease as related to Root-Growth

It has been repeatedly observed in the past few years that deoxyribonuclease (DNase) activity is increased in normal growing animal tissues[1-5]. As postulated by Brody[2], it is possible that the increase in acid DNase activity counterbalances the greatly enhanced activity of the deoxyribonucleic acid (DNA) synthesizing enzymes and indeed determines the normal character of the growth Cancerous tissues, on the contrary, have a lower DNase activity, at least when the activity is expressed per mgm DNA (ref 2), but not, apparently, when it is expressed per mgm nitrogen[6].

In plant roots, the mitotically active meristem can be easily separated from the upper regions where the mitotic activity is very much lower Pea seeds (*Pisum sativum*) were allowed to germinate on paper soaked with distilled water for 3 days at room temperature Roots of approximately equal length were then selected and cut in two fragments the tip, 1 5–3 mm long, and a longer fragment immediately above the tip The mitotic indices determined on sections of each fragment after Feulgen staining gave values of 35–45 a thousand in the tip and less than 1 in a thousand in the upper fragment

Fifty to hundred fragments of each kind of the same length are pooled and homogenized in cold distilled water in a Potter tube A sample of the homogenate is pipetted for total nitrogen determination by the Kjeldahl method The rest is used for measurements of DNase activity by viscosimetry at 37° C (ref 7) The activity of the acid enzyme is measured in acetate buffer 0 2 *M* *p*H 4 8 in the presence of sodium citrate (final concentration 0 017 *M*) and highly polymerized DNA (final concentration 0 4 mgm /ml) prepared from calf thymus[8] For neutral DNase, phosphate buffer 0 2 *M* *p*H 7 6 with magnesium chloride (final concentration 0 04 *M*) is used 0 02 ml 'Triton-*X* 100' 10 per cent is added just before introduction of the mixture into the viscosimeter The activity is expressed by the initial rate of decrease of the specific viscosity extrapolated to 10 min , or by the actual decrease in 10 min when a straight-line relationship with time is obtained For determination of the DNA content, at least one hundred root segments, cut exactly as for DNase assays, were homogenized in 70 per cent ethanol and processed according to the method in ref 9, a small modification was introduced and consisted in incubating the delipidated tissue in cold 2 *N* perchloric acid for 18 hr in order to get a better extraction of the ribonucleic acid (RNA) A diphenylamine reaction (Burton[10]) was performed on the hot perchloric extracts A sample of the alcoholic homogenate was pipetted for nitrogen determination the expression of DNase activity/mgm DNA rendered it indeed necessary to make a correction for any small differences in nitrogen content which might occur between the segments selected for DNA determinations and those selected for enzymic assays

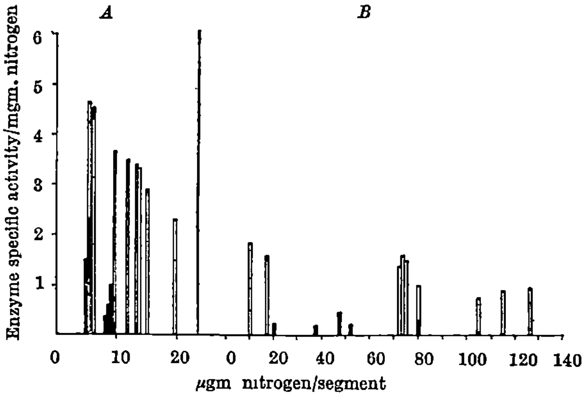

Fig 1 Specific DNase activity in two different segments of the pea root *A*, Tip of root, *B*, upper fragment (see text), white bars, acid DNase, black bars, neutral DNase

In Fig 1, the specific activity of DNases/mgm nitrogen is given for the tip of the root (part *A*) and for the upper fragment (part *B*) The length of the segment is indicated by the values of total nitrogen/segment, in μgm , on the abscissæ It is clearly seen that the specific activity of acid DNase is much higher in the tip than in the other part of the root, the shorter the tip fragment, the higher the specific activity Neutral DNase is also higher in the tip, but the difference between the two fragments is less marked than for the acid enzyme

In Table 1, the specific activity of acid DNase expressed per mgm nitrogen can be compared with the specific activity expressed per mgm DNA in four experiments

The ratio of enzyme activities between the tip and the upper part of the root ranges from 1 to 2 58 when the activity is expressed per mgm DNA and from 2 to 6 65 when it is expressed per mgm nitrogen

Table 1 DNA and Nitrogen Content and DNase Activity in Two Different Fragments of the Pea Root

	μgm DNA/ segment	μgm nitrogen/ segment	Acid DNase/ segment	Acid DNase/ mgm. DNA	Acid DNase/ mgm nitrogen
Tip	1 9	13 8	0 042	22 5	3 05
Upper part	6 7	75	0 124	18 5	1 53
Tip	2 8	19 8	0 045	15 6	2 27
Upper part	6 2	115	0 098	15 6	0 84
Tip	1 72	13 4	0 046	26 8	3 41
Upper part	10 5	126	0 109	10 4	0 86
Tip	1 32	9 8	0 036	27 3	3 66
Upper part	4 60	103	0 058	12 6	0 55

Thus, as in many animal tissues, the acid DNase seems also linked to the process of growth in pea roots Of course, many syntheses are going on at a high rate in the meristem, for example RNA, protein and DNA syntheses[11], but the metabolism with which the DNase is more probably connected is the DNA metabolism. It is known, however, from ref 12 that DNA synthesis goes on in the older cells above the meristem and that there is up to four times more DNA per cell during elongation, without mitosis. This fact has been confirmed on *Vicia faba* roots[13], it was observed by autoradiography that ^{3}H-thymidine was incorporated into the nuclei up to 7 mm behind the meristem, with decreasing intensity

Therefore, the decreased activity of acid DNase in the upper part may be a mere reflexion of a lower rate of DNA synthesis, or may indicate that DNase is also connected with the mitotic process and markedly decreases because the mitotic activity shows a dramatic drop above the meristematic part of the root.

The help of Dr Demalsy for the Feulgen staining is gratefully acknowledged

Enterohepatic Circulation of Bilirubin

The enterohepatic circulation of bile pigment has been the subject of protracted debate Recirculation of bilirubin, and its bacterial reduction products, the urobilinoids, has been postulated and denied[1]. The availability of bilirubin labelled with carbon-14 in this Laboratory[2] has obviated many of the problems previously inherent in the study of bilirubin metabolism The following is a preliminary report of investigations of the enterohepatic circulation of bilirubin

Radioactive crystalline (unconjugated) bilirubin was prepared by methods described previously[2] Radioactive conjugated bilirubin (in bile) was prepared by infusing crystalline labelled bilirubin intravenously into rats with an external bile fistula Essentially all the injected label was excreted in bile as conjugated labelled bilirubin during the ensuing 3-hr. period

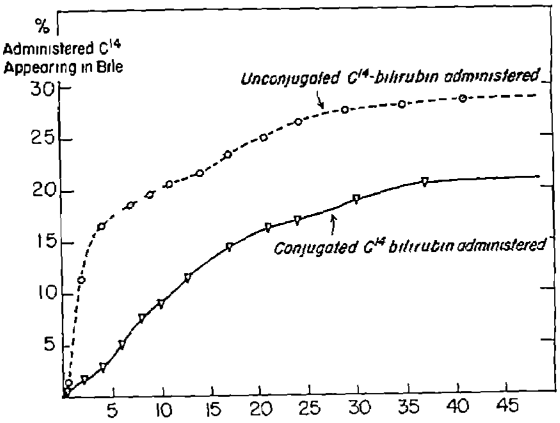

Fig 1 Appearance of radioactivity in bile following intraduodenal infusion of either conjugated bilirubin (▽——▽) or unconjugated bilirubin (○ – – – ○) labelled with carbon-14

For work on intestinal absorption, crystalline labelled bilirubin was dissolved in aqueous taurocholate, human albumin solution, or normal rat bile prior to administration, while conjugated labelled bilirubin was administered in bile The labelled bile pigments were infused through a transoral duodenal feeding tube into each of 9 rats with an external bile fistula The rats were allowed to recover from anæsthesia, and maintained, thereafter, in restraining cages permitting complete separation and recovery of excreta After infusing the labelled pigments into the duodenum, collections of bile, urine, and fæces were made at regular intervals for determination of total radioactivity Bilirubin was crystallized[2] from selected pooled samples of bile and the specific activity determined At the termination of each experiment animals were autopsied to ascertain the absence of operative complications and the persistence of the bile duct catheter *in situ*

Table 1 RADIOACTIVITY RECOVERED AFTER INTRADUODENAL ADMINISTRATION OF CONJUGATED AND UNCONJUGATED BILIRUBIN LABELLED WITH CARBON-14

	Infused radioactivity recovered in excreta (per cent) Conjugated ^{14}C-bilirubin	Unconjugated ^{14}C-bilirubin
Bile	21	28
Urine	2	trace
Fæces	40	32
Total	63	60

Data based on radioactivity recovered in two rats during the 72-hr period following intraduodenal administration of either 0 13 μc conjugated labelled bilirubin or 0 25 μc unconjugated bilirubin in a final volume of 2 ml at similar bilirubin concentrations

Representative results are given in Fig 1 and Table 1 In all instances, significant intestinal absorption and biliary excretion of the carbon-14 label were evident After the intraduodenal administration of both unconjugated labelled bilirubin and conjugated labelled bilirubin, much of the demonstrable absorbed radioactivity appeared in the bile as conjugated labelled bilirubin The initial phase of absorption was more rapid for unconjugated bilirubin than for conjugated bilirubin and the total absorption of the former appeared somewhat greater Little radioactivity was recovered in urine

BIOLOGY

Effect of Pupal Brain Surgery on the Rocking Response of *Automeris*

THE rhythmic rocking responses of Hemileucine moths may be released from insects which have been subjected to quite drastic surgical procedures[1], but they have never been observed in decapitated preparations[2] An attempt has now been made to investigate the role of the brain in mediating this response and in determining its quantitative strength, using the techniques of pupal surgery described by Williams[3] One hundred female pupæ of *Automeris cinerea* were chilled at 6° C. for eight weeks immediately following their reception from Argentina, and were then transferred daily (at 25° C) in batches of five in order to break diapause On the fifth to eighth day after transfer, they were chilled at 4° C for 1 hr , anæsthetized in carbon dioxide for 30 min while packed round with melting ice, and subjected to gross brain surgery through a window cut in the facial cuticle After surgery, the pupæ were sealed with the usual precautions[3] and returned to 25° C. The yield in terms of histologically acceptable lesions was approximately 50 per cent The surgical procedures, which were previously rehearsed on the large Indian *Antherea mylitta*, are summarized in Fig 1 It may be noted that while procedure 1 results in blind moths the optic glomeruli II and III of which remain intact, procedure 2 ablates the entire optic complex, while sparing the medial lobes of the protocerebrum Procedure 5 permits the development of a recognizable suboesophageal unit in isolation; while the resulting neuropil shows evidence of condensation, the normal features of its intrinsic organization may readily be recognized in favourably oriented sections, and moths so treated differ characteristically in their behaviour from those from which the suboesophageal ganglion has been extirpated.

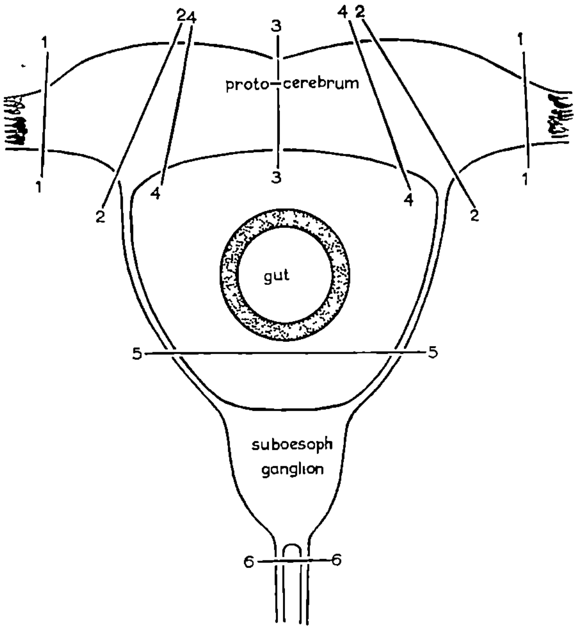

Fig 1 Diagram showing the pupal brain, and the six surgical procedures

Some 12 hr before emergence was due, and just after the absorption of the moulting fluid, each surviving moth was dissected from the pupal case, and its settling behaviour examined by the techniques which have been described in ref 2, some individuals were kept at 20° C and tested at intervals. The rocking response of *A cinerea* does not show the quantitative stability of that of *A aurantiaca*[2], and repeated testing at 5-min intervals typically yields a range of scores lying between 10 and 45 The brains of all moths were dissected out, fixed in Dubosq–Brasil solution, sectioned at 10μ, and impregnated by a modification of the Holmes[4] technique, similar to that of Larsen[5] but using 2,6-lutidine in place of pyridine

The results are summarized in Table 1; the left-hand column records the effective surgical procedure as scored at histological examination The highest

scores for each moth are marked with an asterisk, they may be compared with the highest response strengths scored for each of seven females at first settling after spontaneous hatching (38 , 36 , 43 , 34 , 17 ; 42 , 45), and with the scores yielded by 66 males aged 8–24 hr when settling for the first time following a disturbance[6] (mean = 23 39, σ = 11 53) Despite the striking abnormalities of behaviour characteristic of each lesion, the co-ordination of the rocking response was unaffected except by procedures 2 and 3 in combination, where the amplitude of the response was increased the only moth which gave a weak response after procedure 4 showed oscillations of shallow amplitude While this latter procedure necessarily ablates the medial protocerebral neurosecretory cells, and the corpora cardiaca and allata, procedures 5 and 6 eliminate the rocking response whether or not the brain and its associated organs are left *in situ* The role of the protocerebrum cannot, therefore, merely be that of providing endocrine priming for the lower neural structures Furthermore, while eserine potentiates the rocking response of intact moths, it is unable to cause its re-appearance in decapitated animals[6].

These results show that for *A cinerea* (i) protocerebral structures are necessary for the facilitation of the rocking response, which cannot be performed in their absence, (ii) within the limits of these experiments the quantitative strength of the response is independent of input from the optic complex, and (iii) it is probably independent of transverse connexions at the protocerebral level

I am grateful to Prof J B S Haldane and Dr Helen Spurway for sending pupæ of *A mylitta* from Calcutta The work was supported by grants from the University of London Central Research Fund, and from the United States Department of Health, Education and Welfare (Project *RG*-7109)

Role of Cell Division in Gastrulation of the Viviparous Toothcarp *Xiphophorus helleri*

Recently it was stated that morphogenetic movements in gastrulation of the viviparous teleost *Fundulus heteroclitus* occur in a normal fashion in cases in which cytokinesis is prevented by treatment with the antimitotic alkaloid colchicine[1] To establish whether a more general significance should possibly be attached to this phenomenon a corresponding investigation was performed with a fish bearing live young, namely the viviparous cyprinodont *Xiphophorus helleri*, the swordtail For this purpose pregnant females in the first phase of gestation were injected intraperitoneally with 0 5 ml of 0 001 *M* colchicine solution During gastrulation in stage 12 (beginning gastrula), 13 (advanced gastrula), 14 (further advanced gastrula) and 15 (closure of blastopore) both treated and control females were killed by decapitation and the ovaries were fixed in Bouin's fluid The blastoderms were sectioned at 5μ and stained with Heidenhain's iron hæmatoxylin The mitotic index, representing the ratio of cells in mitosis to the total number of cells, and expressed as per cent, was determined in each blastoderm on the basis of cell counts of the sections

Table 1 Mitotic Indices of Colchicine-treated and Control Embryos of *Xiphophorus helleri*

Stage 12 = beginning gastrula, 13 = advanced gastrula, 14 = further advanced gastrula, 15 = closure of blastopore

Stage	Mitotic index (per cent) Colchicine treatment	Control
12	6 9	2 2
13	15 3	2 4
14	28 4	3 0
15	35 6	3 7

As in *Fundulus*[1], also in *Xiphophorus* the colchicine treatment did not have any apparent effect on gastrulation, which was similar to that in control blastoderms and consequently morphologically normal The colchicine-treated blastoderms showed typical c-mitoses[2] On the strength of mitotic index determinations for control and colchicine-treated blastoderms it could be established that in the treated blastoderms the number of *c*-mitoses increased, indicating that mitosis was completely blocked (Table 1) Thus, in stage 15, 35 6 per cent of the cells are in mitosis, while the mitotic indices of control blastoderms are relatively low during gastrulation Consequently, also in early morphogenesis of viviparous teleosts cell division can be dismissed as a causative factor and apparently provides only material for morphogenetic movements[3] This result, corresponding very well with the findings of Kessel[1] obtained with *Fundulus* and consequently of more general importance, is an argument for the view that gastrulation is a problem of mass movements and not of growth[4,5]

Oxidase Activity in the Saliva of a Plant-Bug

In an account[1] of the origins of the salivary materials of a lygæid, *Oncopeltus fasciatus* (Dall.), it was reported that an oxidase other than cytochrome oxidase occurs in the accessory gland of the salivary apparatus, but not in the principal gland. No direct evidence was put forward for the discharge of the oxidase during salivation, but it was stated that the stylet-sheath material shows non-enzymic oxidizing properties that are not apparent in the precursors of the sheath material in the anterior and lateral lobes of the principal gland It was therefore suggested that an oxidase from the accessory gland acts on the precursors as they are discharged However, other evidence put forward suggested that the secretion of the accessory gland is a normal constituent of the watery saliva, which can be discharged independently of the sheath material Evidence for the existence of an oxidase in the watery saliva of another lygæid, *Aphanus sordidus* Fabr (the peanut trash bug or groundnut bug), has now been obtained, together with further evidence for the oxidation of the sheath precursors as they are discharged

The principal and accessory salivary glands of *Aphanus* were dissected into insect Ringer's solution and immediately transferred to Burstone's oxidase reagent[2], with or without inhibitors In the absence of inhibitors, the cells of the entire salivary apparatus coloured within half a minute, in the presence of 0 003 *M* potassium cyanide, there was no reaction, and in the presence of 0 003 *M* sodium azide, the whole of the accessory gland and the principal salivary duct, but no other part of the salivary apparatus, were coloured In view of Burstone's report[3] that cytochrome oxidase is inactivated if tissues are left in physiological saline for 30 min , it was interesting to observe that salivary glands which had been left in Ringer's solution overnight and were then transferred to the oxidase reagent showed the same reaction as fresh glands incubated in the reagent plus azide, that is, only the accessory gland and salivary duct were coloured When the lobes of the principal gland were ruptured in the reagent, either with or without azide, the emerging contents did not become coloured and no coloured precipitate was formed

Watery saliva was collected from the insects by forcibly extending the rostrum and collecting the liquid which exuded from the tip The salivation of bugs in these circumstances was erratic often no saliva could be collected, but sometimes a bug appeared to salivate so freely that the whole of the rostrum and head capsule became bathed in liquid To provide against the possibility that the latter phenomenon was due to bleeding caused by damage to the bug during handling, tests for oxidase activity were made both on the liquid assumed to be watery saliva and on blood withdrawn from the insect by puncturing an abdominal intersegmental membrane with a fine pipette

When the collected saliva was discharged into a drop of reagent on a white tile, a purple-blue precipitate formed, usually within a few seconds, and a blackish-purple border began to form around the drop of reagent within 5 min In contrast, the reagent alone left only a pink residue when it evaporated The insect's blood gave no reaction When the saliva was discharged into the reagent diluted with an equal volume of 0 005 *M* potassium cyanide, a slow, weak reaction occurred, and there was no reaction if the saliva was first mixed with its own volume of cyanide and then discharged into the reagent On the other hand, when the saliva was first mixed with 0 005 *M* sodium azide or with water, a rapid reaction occurred.

Sheath material was collected as the 'collar'[4] left at the surface of feeding punctures on peanuts In the oxidase reagent, the sheath material developed no more than a faint pink colour, and there was thus no evidence for oxidase activity in the material itself. However, experiments with oxidation-reduction indicators showed that the sheath material had a higher oxidation-reduction potential than the contents of any of the lobes of the principal gland A satisfactory indicator was 0 01 per cent thionin blue in veronal-acetate buffer *p*H 7 0 Before use, it was reduced by the dropwise addition of 1 per cent sodium dithionite until the indicator was almost colourless A salivary gland was dissected into a drop of insect Ringer's solution made 0 005 *M* with respect to potassium cyanide, and pieces of fresh sheath material were placed alongside All the lobes of the principal gland were punctured and the whole was enclosed under a coverslip in the reduced thionin The sheath material and the walls of the gland immediately became coloured, whereas the contents of the gland, which were observed both as they emerged and after some had coagulated, remained colourless On the other hand, when the indicator had first been re-oxidized by exposure to air, the contents of all the lobes stained to some extent, although the contents of only the anterior lobe approached the same intensity of staining as the sheath material

These experiments showed that an oxidase other than cytochrome oxidase is present in the accessory salivary gland and in the salivary ducts of *Aphanus*, that a similar oxidase is present in the watery saliva, and that the stylet-sheath material has a higher oxidation-reduction potential than the contents of any lobe of the principal gland The results are consistent with the view that an oxidase acts on the sheath precursors as they are emitted, however, the presence of a similar enzyme in both the accessory gland and the salivary duct is a complicating feature, since either or both parts of the glandular system could provide the oxidase in the watery saliva and an enzyme which oxidizes the sheath precursors Possibly both parts are functionally similar, and the accessory gland should be considered as purely a development of the salivary duct, as suggested by Baptist[5]

Pre-Harvest Prophylaxis for Infestation Control in Stored Food-Grains

STORED food-grains suffer from considerable losses due to insect infestations in the tropical and sub-tropical regions of the world[1] During post-harvest storage, cross-infestation by insect pests and the multiplication of pests as a result of field-infestation occur in stored grains even within a storage period of a few months in warehouses[2-3] Fumigation with noxious gases such as methyl bromide, carbon disulphide, carbon tetrachloride, hydrocyanic acid, ethylene oxide and others, although of use in the control of most infestations, is not easy for the producer or the warehouse-man to apply[2] Parkin[1] observed that application of such measures unfortunately lags behind the advance of knowledge in all but the most highly developed countries, and even in those is not always so widespread or up-to-date as it could be A new approach has therefore been made to replace the fumigation treatment with a relatively simpler prophylactic spray treatment of the grain under pre-harvest condition, using a chemical of low toxicity for mammals, for the control of pest infestation during post-harvest storage

Canada and the United States have set a tolerance limit of 8 p p m for malathion in stored food products[4] The U K Ministry of Agriculture, Fisheries and Food has permitted the admixture of malathion with raw unprocessed grains for their storage Godavari Bai *et al* [4] observed that more than 50 per cent of malathion from wheat flour was lost in one month through *A*-twill bags. The average concentration of malathion was less than 2 p p m. after two months storage At this concentration, malathion could exert little prophylactic action on pests of stored grain. The possibilities of disinfesting grain under field conditions with malathion spray at its permissible dosage and affording longer protection from cross-infestation by storing it in sacks impregnated with insecticides, were therefore investigated

The panicles of sorghum crop (*Sorghum vulgare*) were sprayed with malathion (Premium grade, American Cyanamid Co) water-dispersible emulsion at various dosages on different plots The grain was harvested, threshed and stored in lindane-impregnated *B*-twill sacklets Grain samples were analysed for malathion by the method of Norris *et al* [6] Sorghum harvested from the control plot was stored in impregnated and unimpregnated sacklets and, for comparison, control grain was fumigated and stored in these bags Experimental grain sacklets were incubated in an infestation room having large populations of *Sitophilus oryza* (Linn) and *Tribolium castaneum* (Hbst) for 150 days

The results of the experiment, shown in Table 1, demonstrated that this simple treatment can replace the fumigation treatments for pest control in stored grain.

Table 1 EFFECT OF PRE-HARVEST SPRAYING OF MALATHION ON THE POST-HARVEST STORAGE OF *Sorghum vulgare*

* Impregnated bag at 75 mgm lindane/sq ft
† As a result of field-infestation
‡ Grain fumigated with 32 mgm /litre methyl bromide for 48 hr

In most cases stored food-grains are fumigated in warehouses only when they show open signs of insect infestation, for untrained warehouse-men, in the tropics and in many other parts of the world, cannot detect incipient infestation On the other hand, field-spraying of crops with a pesticide is much more commonly adopted throughout the world The newer pesticidal substances having differential toxicities[7] to insect pests and mammals, such as malathion, present a unique means of introducing simple pest control treatments for stored food-grains. Spraying of malathion on the crop before harvest at a required level to obtain a concentration below the permissible limit in the threshed grain and storing in an insect-proofed structure or jute sacks can afford satisfactory protection from pest infestation in post-harvest storage Treatment of harvested grain with malathion would require elaborate machinery for spraying the regulated grain-flow on a conveyor, but applications in the field on the crop would be easy. This new approach to pest control problems of stored food-grains probably offers a simpler solution for large-scale application where fumigation with toxic gases cannot be easily applied. Although malathion is rapidly dissipated from the treated grains, the possible residual toxicity to consumers, of traces of the chemical on food-grains, needs further assessment in the present context

We thank Dr. V Subrahmanyan, director, and Dr A Sreenivasan, deputy director, of this Institute, for their interest in the work

Perennial Nodules on Native Legumes in the British Isles

IT is generally maintained that the normal life span of legume nodules in temperate climates is restricted to one season or growth cycle of the host plant Frost, drought[1] and insect damage[2], or developmental changes in the host such as flowering and fruiting[3], are recognized agencies leading to destruction of nodules

Nodules on certain tropical woody legumes and perennial species of *Lupinus* are classed as exceptional in developing annual or seasonal increments of bacterial tissue Various anatomical features are associated with the prolonged activity of such perennial nodules[4].

In an earlier paper[5] a successful over-wintering of nodules was described as a common event in winter annual, biennial and perennial legumes in Northern Ireland. During four seasons of investigation (1952–56) involving 29 native species, a life-span of 10–20 months was recorded for nodules surviving into a second season No evidence was obtained of nodules persisting into a third season of plant growth.

This communication reports the finding, in February 1961, of what are considered to be truly perennial nodules on the roots of gorse (*Ulex europaeus* L) and broom (*Sarothamnus scoparius* Koch) growing on drained peat bog near Randalstown, Co Antrim The nodules are multibranched structures measuring some 1–1½ in in length and weighing as much as 1 gm They are borne on thin fibrous roots traversing the upper layers of partially decomposed peat. Many show apogeotropic growth forms similar to those to be observed in root nodules of *Alnus* and various cycads.

The following findings support the view that the nodules are several years old and clearly equipped for at least another season of growth and nitrogen fixation :

(1) 3–6 annual growth rings can be counted in the parent roots of the larger nodules This suggests that the nodules are of a similar age, since nodule formation in both gorse and broom occurs at infection sites underlying the piliferous layers of very young roots

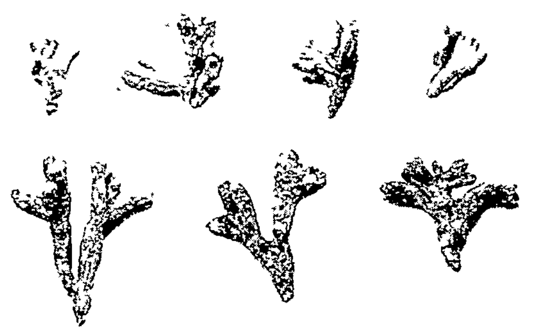

Fig 1 Perennial nodules on native legumes in Britain Upper row from broom, lower row from gorse Material obtained from a drained peat-bog, near Randalstown, Co Antrim, N Ireland (× ½)

(2) A mature nodule may show many constrictions along its length (Fig 1) These constrictions apparently demarcate seasons of growth activity

(3) Sectioning reveals several features reminiscent of those described for perennial nodules by other writers[4,6] Outer layers of the nodule cortex develop heavy suberization in all mature parts of the nodule Vascular tissue persists in healthy condition in older portions of the nodule, although all other inner tissues decay and may even disappear with age Healthy meristems terminate each nodule lobe Behind these occurs a zone of bacterial tissue pigmented with hæmoglobin Adjacent older tissues show an accumulation of green bile-type pigments The nodule cortex in these younger regions contains abundant starch, particularly in lines of cells adjacent to the vascular tissue Paper chromatography of the soluble-nitrogen fraction reveals that aspartate, glutamate, and their respective amides, asparagine and glutamine, accumulate in quantity in the nodule The latter amides and starch are the principal storage products in other parts of the over-wintering plants

It would be interesting to know whether perennial nodules are developed on native or introduced legumes in other parts of the British Isles. Nodules on gorse and broom are clearly equipped anatomically for perennation, yet this event may be achieved in Nature only after a series of mild winters, and possibly only in soil conditions where decay of older parts of the nodule is arrested.

Cultivation of Goitrogenous and Non-Goitrogenous Cabbage

RESULTS of earlier work on the goitrogenous properties of plants[1-3] supported the assumption that goitrogenous activity of vegetable foodstuffs, particularly that of *Brassica* species, depends to a large extent on the content of sulphur compounds as goitrogenous substances Therefore, in an attempt to supply experimental evidence for the relationship between cabbage goitrogenicity and the intake and rate of utilization of sulphates from nutrient environment, cabbage (*Brassica oleracea*, var. *capitata*, subsp Amager) was cultivated in pure silica sand (SiO_2), in vegetation pots, by means of nutrient solutions in which only the sulphate content was made to vary The results of the first experiment in this series had confirmed the above assumption, namely, that goitrogenous activity of the cabbage increased in relation to the sulphate content in the nutrient solution[4,5] However, efforts to grow cabbage without goitrogenous properties had failed In the second experiment I endeavoured to grow both the goitrogenous and the non-goitrogenous variants of cabbage side by side The same species of cabbage was again grown in vegetation pots with silica sand by means of nutrient solutions The composition of the solutions for variants I and II is given in Table 1

Table 1 COMPOSITION OF NUTRIENT SOLUTIONS

Type of nutrient salt ions	Concentration of nutrient expressed in mgm equivalents/l of nutrient solution Cabbage var I	Cabbage var II
Sulphate	1	25
Nitrate	25	23
Magnesium	8	8
Calcium	15	15
Phosphate	8	8
Potassium	12 66	12 66
Ammonium	0	2
Chloride	8	0
Sodium	1	10

Iron and micro-elements added in equal amounts expressed in mgm /l of nutrient solution for both the cabbage variants

Iron	5 0 mgm	(0 025 gm of ferric citrate)
Manganese	1 0 mgm	(0 00406 gm $MnSO_4$ $4H_2O$)
Copper	0 1 mgm	(0 0003928 gm $CuSO_4$ $5H_2O$)
Zinc	0 1 mgm	(0 0004397 gm $ZnSO_4$ $7H_2O$)
Boron	0 5 mgm	(0 002858 gm H_3BO_3)
Molybdenum	0 02 mgm	(0 000037 gm $(NH_4)_6Mo_7O_{24}$ $4H_2O$)

Beginning with the second half of the growth period, all sulphates were withdrawn from the nutrient solution for variant I by leaving out 1 mgm - equivalent of sulphate ion and sodium ion. The remaining nutrients, such as iron and microelements, continued to be supplied in equal amounts to the nutrient solutions for both the cabbage variants, as seen in Table 1 At the end of the period of growth the content of sulphur compounds was determined in both the variants. Total and inorganic sulphur, expressed in terms of sulphates, was determined gravimetrically, thiocyanates according to Aldridge's method[6], and SH-compounds polarographically according to Zuman[7] The results are summarized in Table 2

It was found that the content of total, inorganic and organic sulphur is several times greater ($P \leqq 0 0005$) in cabbage variant II than in variant I Thiocyanate content of variant II was likewise significantly higher ($P \leqq 0 02$) The values for SH-compounds were significantly higher ($P \leqq 0 001$) in the green leaves of variant II than in those of variant I, while no differences were noted in the cabbage heads In general, the content of sulphur compounds, with the exception of thiocyanate and SH-compounds, was markedly higher in the green leaves than in the cabbage heads

The goitrogenous activity of the cabbage variants was assayed on rats, where the relative thyroid weights, the thyroidal iodine-131 uptake in 24 hr. and the level of protein-bound iodine-131 in serum were followed and a histological evaluation of thyroid preparations was made A strong goitrogenous activity was observed in rats fed with cabbage variant II, while variant I failed to show any activity when the

Table 2. Results of Sulphur Compound Determinations in Cabbage

Type of test (n = 10)*	Variants of cabbage			
	I		II	
	Green leaves	Cabbage heads	Green leaves	Cabbage heads
Desiccated cabbage (per cent)	11.64 ±1.48	8.36 ±0.58	10.58 ±1.76	8.46 ±1.34
Total sulphur in mgm per cent sulphate	46.6† ± 9.6	66.1 ±29.5	427.3 ±208.1	164.0 ±45.6
Inorganic sulphur in mgm per cent sulphate	17.3 ± 8.2	34.1 ±29.1	322.8 ±156.2	89.6 ± 42.5

† Average ± *S.E.*

results were compared with those from a control group of rats, which had received Larsen's diet only. The nutritional value of both the cabbage variants was the same, for I failed to notice any significant differences in the sugar content, vitamin C, total nitrogen and calcium values between the two cabbage variants.

The plant material as defined here, considered from the point of view of cultivation, and the possibility of cultivating goitrogenous and non-goitrogenous variants of cabbage side by side, offer new opportunities for experimental research in this field.

I am grateful to Mr. Š. Kaločai, Mrs. J. Schillerová and Mrs. K. Gschwendtová for their technical assistance, and to Mr. P. Tkáč for translating the text into English.

Biologically Active Materials in Coal

That materials extractable from coal with polar organic solvents inhibit the growth of certain bacteria and fungi has been known for some years[1–5]. The name 'vitricin' has been applied to the group of biologically active substances found in coal[1]. Mills recently reported work on acetone and methanol extracts of coals of various ranks[5]. He found that bacteriologically active extracts contained acidic, basic, neutral, and phenolic components; attempts to separate active components by extraction of ethereal extracts with aqueous acids, alkalis or buffers met with little success. Testing the crude extracts against *Bacillus subtilis* in nutrient broth demonstrated bacteriostatic activity of the solute at a concentration of 30 µgm./ml. Mills did, however, by steam distillation of an acetone extract of Tupton coal (high-volatile bituminous), obtain an oil fraction which inhibited Gram-positive bacteria and certain moulds.

Research workers at the Federal Bureau of Mines prepared and investigated several methanol and acetone extracts of various coals. In agreement with previous workers[3–5], the most active extracts were obtained from high-volatile sub-bituminous or bituminous coals. Peat and lignites yielded lesser amounts, and anthracite practically no acetone- or methanol-extractable material. Contrary to Mills's observations, the most active material obtained was the 5 per cent aqueous sodium hydroxide-soluble fraction from ether solutions of materials obtained by acetone extraction of coals high in volatile matter. This material, recovered from the hydroxide solutions by precipitation with acid and centrifugation, was active in nutrient broth dilution tests against *Bacillus subtilis* at concentrations of 5–10 µgm./ml.

We recently obtained a large sample of material for more detailed study by treating 200 lb. of a high-volatile sub-bituminous *B* coal (Rock Springs, Wyoming) with 150 gal. of acetone. The work was carried out at room temperature on coal ground to pass a 200-mesh screen. When the solvent was evaporated, a brownish-black, soft tarry material remained. This represented about 1 per cent of the original weight of coal. Previous observations were confirmed with this extract.

A 400-gm. sample of the extract was subjected to steam distillation and 14 ml. (11.6 gm.) of a volatile yellow oil was obtained. The oil was separated into its acidic, phenolic, basic, and neutral components and these were tested in nutrient broth against *Bacillus subtilis*. Only minor activity was observed in the case of the acidic (partial inhibition at 100 µgm./ml.) and phenolic (partial inhibition at 40 µgm./ml.) fractions.

A 50-gm. sample of the residue from the steam distillation was cooled to − 68° C., crushed, and agitated for 5 min. in a Waring blender with 10 per cent (w/v) aqueous sodium hydroxide. The resulting suspension was mixed with a small amount of 'Celite' and then filtered. The filtrate was acidified with 6 *N* hydrochloric acid and extracted with ether continuously for 16 hr. This procedure yielded 6.4 per cent of the original residue. The hydroxide-soluble material inhibited *B. subtilis* at a concentration of 8 µgm./ml. in nutrient broth.

To confirm that phenolic materials were responsible for the observed activity at 8 µgm./ml., the trimethylsilyl ethers ($(CH_3)_3SiOR$) of the phenolic hydroxyls were prepared. A small sample of the hydroxide-soluble material was refluxed with hexamethyldisilazane for 8 hr. After refluxing, residual hexamethyldisilazane was removed by warming in a vacuum. The reacted material was active against *Bacillus subtilis* at a concentration of 40 µgm./ml. The reacted material then was refluxed for 6 hr. in ethyl alcohol (70 per cent v/v) to hydrolyse the trimethylsilyl ethers, and then heated (54° C.) *in vacuo* to remove the alcohol, water, and hexamethyldisiloxane formed during the reaction. The reconstituted material was active against *B. subtilis* at 8 µgm./ml. of nutrient broth and confirmed complete recovery of the originally observed activity.

The original acetone extract and samples obtained at the various concentration stages were analysed by mass spectrometry and were also examined in the ultra-violet. Mass spectrometer analysis of the total acetone extract showed peaks at mass units (in order of decreasing intensity) at 342, 324, 374, 376, 340, 350, and 392. These masses indicate a range of compounds in the six-ring series. Since ultra-violet spectra indicated a high percentage of three-ring systems, the six-ring compounds detected by mass spectrometry probably consist of diphenanthryl, or similar systems Control runs with acetone alone (no coal) demonstrated that polymerized solvent was not responsible for the mass peaks observed

The acetone extracts differed mainly from the parent coal in elemental composition in having a higher hydrogen content Analyses showed (per cent)

Coal C, 79 31, H, 5 41, N, 1 74, S, 0 90, O, 12 65, ash, 1 96

Extract C, 78 87, H, 9 92, N, 0 23, S, 0 21, O, 10 92, ash, 0 02

Acetone might be expected to extract more polar compounds from the coal matrix, enriching the oxygen content of the extract, but apparently this did not occur The oxygen content of the extract was 10 92 per cent, that of the whole coal 12 65 per cent Perhaps materials soluble in acetone serve as solvents for other materials in the coal which are not acetone-soluble On long contact with the coal, the extract then serves as a continuously changing solvent, contrasted to a soxhlet-type extraction, with resultant extraction from the coal of materials of high mass and low oxygen content

Calculation of the amounts of hydroxide-soluble materials present in the original coal indicate a concentration of 150 μgm /gm of coal The material inhibits the test culture at 8 μgm /ml of broth It is possible that such materials play a part in the resistance of coal to biological oxidation, and the limitation of the coal flora[6] to non-susceptible forms

MICROBIOLOGY

Relationship between Phage Type and Host Plant in *Pseudomonas mors-prunorum* Wormald

Pseudomonas mors-prunorum causes bacterial canker of cultivated *Prunus* spp. in England and is widely distributed on the plum (*P domestica*) and on the cherry (*P avium*) Strains from plum and cherry show some degree of pathogenic adaptation to their original host[1], but have not been distinguished by routine physiological or biochemical tests We now find that we can differentiate between them by phage typing

The bacterial strains used in these experiments were collected over a period of 7 years from plum and cherry plantations within a restricted geographical area of about a half-mile square at East Malling Research Station in Kent Bacteria were isolated from leaf surfaces, rain-water draining down the trees, and lesions on branches or foliage. The typing phages, with the original propagating host species in parenthesis, were as follows *A*1, *A*2, *A*3, *A*7, *A*32 (*P mors-prunorum*) and *S*3 and *S*8 (*P. syringae*) These phages were selected from a group of 57 isolated from soils by a method previously described[2] The phages were purified by repeated selection from single plaques, and stored as high-titre preparations of approximately 10^{10}–10^{11} particles/ml over chloroform at 4° C In these conditions most of the preparations have remained stable for two years

For phage-typing, 10^7 viable cells of the bacterial isolate under test were poured into plates with 12 ml of a medium having the following composition· 0 3 per cent Difco yeast extract, 0 5 per cent Oxoid bacteriological peptone, 2 0 per cent glycerol, 1 0 per cent B.D H Japanese agar When set, the plates were dried with the lids removed for 2 hr at 30° C and then spotted with 0 02 ml of the phage preparation at the routine test dilution, that is, the lowest dilution giving confluent lysis on the original propagating strain Finally, the plates were dried for about another hour and incubated overnight at 25° C The results of tests on plum and cherry strains are summarized in Table 1 and compared with similar tests on *Pseudomonas syringae* isolates obtained from diseased pear blossoms in widely separated localities of south-east England during 1959–60

		s	–	*s*	–	–	+	+

+, Confluent lysis, (+), innumerable plaques, *s*, isolated plaques, –, no reaction

Within each species or strain group there were different phage types The plum strains of *P mors-prunorum* differed from the cherry strains in failing to react with phages *A*2 and *A*7, and in giving no reaction or isolated plaques with *A*3 They were also less sensitive to *A*32 They resembled *P syringae* in typing pattern, except that, as a group, they were more sensitive to *A*1 and less sensitive to the *P syringae* phages *S*3 and *S*8 One plum isolate gave a typing pattern identical with one of the *P syringae* isolates

Phage sensitivity does not appear to be correlated with biochemical activities All the *P mors-prunorum* isolates tested, for example, were physiologically homogeneous and quite distinct from *P. syringae* in respect of the characters shown in Table 2

Over the period of 7 years during which the *P. mors-prunorum* strains have been collected there have been no signs of any major change in the phage types associated with cherry or plum in the field Some strains have been in culture for several years

Table 2 BIOCHEMICAL DIFFERENTIATION OF *P mors-prunorum* AND PEAR ISOLATES OF *P syringae*

P syringae	+ *	+	+	–	yellow

* One isolate failed to hydrolyse æsculin and arbutin

without passage through the host and appear, therefore, to be relatively stable *in vitro* The difference between the plum and cherry strains may merely reflect a different history of phage-infection in the field The cherry strains, for example, may have failed to acquire resistance to *A*2 and *A*7 or related phages because these are absent on cherry or their activity is in some way inhibited Alternatively, the phage types may be a result of selection by the host plants This would imply some form of association between phage sensitivity and specific virulence factors in *P mors-prunorum*

Serotonin in the Small Intestine of Conventional and Germ-free Chicks

THE function of serotonin (5-hydroxytryptamine) in the tissues of the small intestine is not understood even though it is found in relatively large quantities, particularly in the enterochromaffin cells[1] The most frequently repeated interpretation ascribes control of intestinal motility and vascular permeability to serotonin[2,3] Thus, if the tonus of the gut is dependent on serotonin-levels, germ-free animals, which possess poor tonus of the tract and distended cæca[4], might be expected to have a lower serotonin content in the gut than conventional animals On the contrary, however, this communication provides evidence that intestinal serotonin-levels are actually depressed by the presence of micro-organisms in the lumen of the gut

White Leghorn chicks were raised in a germ-free environment by methods similar to those previously described[5] on a complete starch-casein diet[6] Fertile eggs were obtained from local hatcheries after 19 days of incubation, immersed in 2 per cent mercuric chloride solution for 10 min at 39° C and put into sterile 'Plexiglas' isolators where they hatched Control chicks were treated in the same manner but were reared in a non-sterile isolator After four weeks the chicks were decapitated, the small intestine was excised and washed in cold water All germ-free animals were examined[7] for bacterial contamination when killed The various segments of the intestine were homogenized in 0 1 *N* hydrochloric acid in a Ten Broek apparatus at 5° C, and serotonin was assayed[8] on fresh specimens in a Turner photofluorometer (G K. Turner and Associates, Palo Alto, California)

Table 1 SEROTONIN IN THE SMALL INTESTINE OF GERM-FREE AN CONVENTIONAL (CONTAMINATED) WHITE LEGHORN CHICKS AT FOU WEEKS OF AGE

Conventional	20	8 3 ± 1 3		6 1 ± 0 8	
Significance of differences by the '*t*' test					
		t	*P*	*t*	*P*
Germ-free vs conventional		0 84	< 0 4	8 8	< 0 01

* Mean ± standard deviation

A significantly higher concentration of serotoni was found in the ileum of germ-free chicks than in control birds (Table 1) This is consistent with the observation[9] that rats and mice given peroral anti biotics produce significant increases of serotonin in the small intestine However, no such difference was apparent in the duodenum (Table 1) There is insufficient evidence to determine whether these results reflect differences between the microflora of the duodenum and ileum or an influence of the intense microbial activity of the cæca[10,11] due to the proximity of the ileum to the latter In any event, the presence of intestinal micro-organisms clearly affects serotonin in the ileum of chicks

Several reports suggest alternative explanations for the microbial inhibition of serotonin A few isolates of *Aerobacter aerogenes* and *Alcaligenes faecalis* appear to be capable of oxidizing serotonin *in vitro*[12] although it is not known if this event occurs in the lumen of the intestine In addition, many species of lactobacilli which are present in large numbers in the chick[13] require pyridoxine or its derivatives[14], pyridoxal phosphate is required as a co-factor in the decarboxylation of 5-hydroxytryptophan to serotonin[15] Thus bacterial removal of the coenzyme may inhibit serotonin synthesis A similar effect might be achieved by the interaction of a bacterial product with the coenzyme such as has been reported for norepinephrine and 3,4-dihydroxyphenylalanine[16]

Further work is required to determine the reason for the difference in intestinal serotonin between germ-free and conventional chicks and the physiological significance of this observation

This work was aided by research grants *E*–2999 and *A*–2660 from the U S Public Health Service

VIROLOGY

A New Mutant of Dermovaccinia Virus

During the course of serial one-day egg passages of a strain of the chorioallantoic membrane-adapted dermovaccinia virus (*DIE* strain)[1], a new minute pock mutant was observed. This arose at the 13th one-day egg passage, when tiny pocks mixed with larger pocks typical of dermovaccinia were seen. The former increased in proportion during further one-day egg passages, and finally excluded the original virus. The mutant strain (*DIs*) was obtained in a pure form by two cycles of clone purification. These were initiated by a single pock produced on one chorioallantoic membrane by the inoculation of limiting dilutions of the fifteenth one-day egg passage. Some biological characteristics of this mutant were investigated and are described in this communication.

(1) *Serological specificity.* The strain *DIs* was neutralized specifically by antivaccinia rabbit serum, but no neutralization was observed by normal rabbit serum or by antiherpes simplex rabbit serum. When inoculated on to the chorioallantoic membrane of 12-day eggs, it produced vaccinia–common complement-fixing antigen and hæmagglutinin. These were separable from infectious particles by differential centrifugation. As the size of pock of the mutant resembles that produced by a strain of pigeon pox, comparative chessboard complement-fixation tests were carried out. The results summarized in Table 1 indicated no cross-reaction between the strain *DIs* and anti-pigeon pox–pigeon serum, though a slight cross was observed between the pigeon pox chorioallantoic membrane antigen and antivaccinia rabbit serum. This could be eliminated by ether treatment of the antigen.

(2) *Host range.* The strain *DIs* grows well in one-day eggs, on the chorioallantoic membrane of 12-day eggs, in the yolk sac of 7-day eggs and in the amniotic sac of 11-day eggs. No significant growth was observed, however, when it was inoculated into the allantoic cavity of 11-day eggs. When a large amount of the virus was inoculated intradermally into adult albino rabbits, it produced a slight reddening and flat swelling on the first few days, which then waned. The reaction was nearly the same as that observed with variola virus inoculated via the same route. No lesion could be seen following inoculation on to the scarified skin of rabbits. The mutant produced no swelling when inoculated into the rabbit testicle, no keratitis when inoculated on to the scarified cornea of rabbits. New-born, weanling and adult mice showed no clinical signs, when inoculated intracerebrally, intraperitoneally or subcutaneously. Infection of the scarified plantar skin of weanling and adult mice from an ectromelia-free colony failed to give rise to any local symptoms. No clinical symptoms were observed in newly hatched chicks inoculated via the intracerebral, intraperitoneal or subcutaneous routes. Roosters and guinea pigs produced specific antibody without any sign of clinical symptoms after several weekly injections administered via the subcutaneous or the intravenous route.

(3) *Physical properties.* The mutant showed the same resistance to ether as did the parent strain. The infectivity of the mutant was as stable as that of the original strain at low temperatures (−70° C and 4° C). Electron microscopy of the elementary bodies of the strain *DIs*, partially purified by fluorocarbon treatment, indicated that the shape and size of the elementary bodies were approximately the same as

No antigen		0	0	0	0	0			0	0

those of the parent stram The mutant was as labile to heat as the parent strain, showing a marked loss of infectivity after being heated at 55° C for 30 min

(4) *Cytopathogenicity in tissue culture·* A moderate cytopathic effect was observed in primary monkey kidney monolayers culture infected with the mutant No cytopathic effect was observed when HeLa cells and *FL* cells were exposed to the mutant, while typical cytopathic effects accompanied by luxurious growth of virus were shown by the parent strain A cytotoxic effect was observable with *L* cells, when infected with a large amount of either the mutant or parent strains

(5) *Production of hæmagglutinin·* On the chorio-allantoic membrane of embryonated hen's eggs, the strain *DIs* multiplies with concomitant production of hæmagglutinin and complement-fixing antigens However, the ratio of pock-forming units to hæmagglutinin units appeared to be slightly lower (4 6 in $\log_{10}$ units) than that observed in the case of the parent strain (5 05) (ref 2) In HeLa cells in which no visible cytopathic effect could be obtained, a considerable amount of hæmagglutinin was nevertheless produced This was characterized by a low ratio of pock-forming units to hæmagglutinin units (3 0 at the twenty-fourth hour of infection, as compared with 4 46 with the parent strain[3])

These results indicate that the strain *DIs*, a minute pock-size mutant of dermovaccinia, is characterized by a reduced, or absent, virulence.

GENETICS

Segregation-ratio Advantage of Abnormal Hæmoglobins

As a consequence of extensive investigations on abnormal hæmoglobins in Jamaica[1-4], in many instances where this was feasible family studies were undertaken The impression was gained (as suggested in ref 3) that some unusual inheritance patterns energed and for this reason a statistical analysis of the available pedigrees was undertaken Only two of the most significant deviations from the expecte Mendelian ratios will be presented here

Since only limited material was available fron investigations in Jamaica, a search through th literature was undertaken In four publications relevant family studies were reported which hav been included in the analysis It should be pointe out that any deviation from expected ratios fron the Jamaican material was always present too in th same direction in these family studies In the com bined material approximately half the individual are derived from my own investigations, the othe half from ref 5

The results which will be discussed here come from families where one parent has the genotype *AS* and the other the genotype *AC*, these results are presented in Table 1

The most unusual finding is the very uneven distribution of *A* and *C* genes in the offspring of families where the mother has the genotype *AC*—twenty-four *C* against seven *A* with a probability of 0 002 When the father has the genotype *AC* there is no significant difference in the number of the *A* and *C* genes in his children, with, however, a very strong preference for the daughters (as compared with the sons) to carry a *C* gene ($P = 0\ 01$ for sex distribution) A further observation in accord with this is that of the nine children whom I examined from mothers with the genotype *SC*, eight inherited the *C* gene and only one the *S* gene ($P = 0\ 05$)

The finding that deviations from Mendelian expectation do occur is not new Apart from plants and *Drosophila* this is known to happen in *Sciara*, a mosquito[6], in the mouse in relation with the *T* locus (tail formation)[7], and has recently been described in two instances in man Stevenson and Jennings[8] explain the preponderance of affected sons of affected fathers in the dominant condition of ectrodactyly by germinal selection Shaw *et al* [9] describe the marked deficiency of the autosomal dominant condition of aniridia in the offspring of aniridic parents (100 affected for 164 normal children)

The findings reported here might therefore represent the third instance of non-Mendelian segregation ratios found in man and could be explained on the basis of gametic selection or differential gametic survival

It is suggested that the maternal or paternal gamete containing an *X* chromosome and the chromosome carrying the hæmoglobin *C* gene has a considerably better chance to occur or to result in a viable fœtus than the gamete containing the *X* chromosome and the hæmoglobin *A* gene The gamete carrying the *Y* chromosome would not have such a selective preference

</table>

Another possible explanation could be post-zygotic election, although nothing is known concerning xcessive abortions in the families reported here

If one accepts for the time being these findings as pproximately correct and representative, arguments an be presented to explain the high frequencies of he C gene in a small area of Africa For this purpose will postulate that the S gene has a neutral value (in view of the other family investigations which are not eported here, this is probably not true) and that herefore the effect of the C gene would be identical in AC–AS and AC–AA matings Starting with 0 001 per cent AC in a population, one can calculate, using the distribution of A and C genes presented in Table 1, that approximately thirty-two generations (about 800 yr) will be required to bring the frequency to 10 per cent This is a very short period of time and agrees well, therefore, with Neel's suggestion that the C gene must be the effect of a recent mutation, since it has not yet had time to spread beyond the Gold Coast

One might also expect that the number of AC heterozygotes is not evenly distributed among the sexes, the male to female ratio should be approximately 2 3 Only little proof for such a statement is available. For work on incidence of abnormal hæmoglobins in Jamaica[1], results from pregnant women were used, possibly leading to an unusually high figure Schneider[10] finds among 505 Negro blood-donors fifteen males out of sixteen with the genotype AC, but her blood-donors are predominantly male Smith and Conley[11] comment on the fact that of the fourteen cases of AC which they discovered, thirteen were females Garlick and Barnicot[12] find thirteen girls against six boys with the genotype AC in a group of 303 Nigerian schoolchildren with otherwise equal sex distribution

The calculations which I have used here are based on a very small body of material, and although the deviations from Mendelian ratios appear to be statistically significant, more extensive material will be required to confirm the views presented It seems possible, however, that besides balanced polymorphism (as in the case of hæmoglobin S (ref 13)) and a greater potential fertility of unions in which one parent carries a single abnormal hæmoglobin gene[14], still other forces may exist to explain the unusually high frequencies of abnormal hæmoglobins in certain populations

SOIL SCIENCE

Method of measuring Soil Hydraulic Conductivity *in situ*

Soil permeability or hydraulic conductivity is of great importance in the engineering design of foundations, dams, sub-surface drainage systems, irrigation systems, etc In spite of its importance, soil hydraulic conductivity remains one of the most difficult of soil properties to assess Laboratory methods have limitations due to the size of the samples Considerable progress has been made in the development of methods for measuring soil hydraulic conductivity in the field when a water table is present However, water tables are not always present in areas requiring seasonal drainage

In order to overcome some of these difficulties, a new field method of measuring the soil hydraulic conductivity is proposed In short, the method consists of measuring the rate of flow of water out of a cavity beneath a pipe The method bears some resemblance to the piezometer method described by Luthin and Kirkham[1] for the measurement of soil hydraulic conductivity beneath the water table

When water infiltrates into soil from a cavity as shown in Fig 1, for some time after the process of infiltration has started the wetting front forms a sphere around the cavity During this initial phase, the driving force can be considered due to the pressure gradient that exists between the cavity and a locus of points behind the wetting front The force of gravity has negligible effect on the pattern of movement during this initial pressure phase. The duration of the pressure phase depends on the pressure in the cavity and the pressure behind the wetting front as well as the soil properties Measurements during this initial phase should offer a method of determining the hydraulic conductivity of various soil layers or soil horizons The following analysis is based on flow due to pressure forces alone

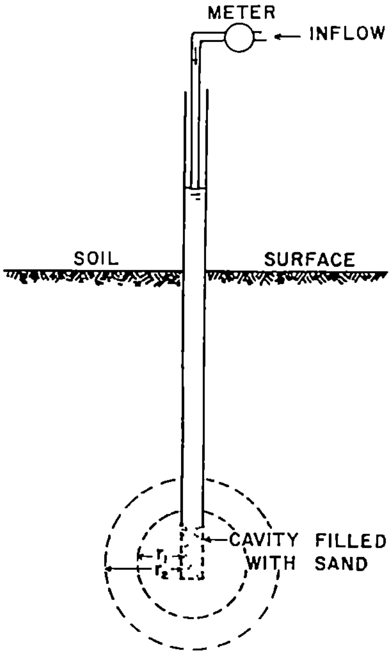

Fig. 1. Diagram of proposed method of measuring the soil hydraulic conductivity *in situ*

The assumptions which are made with regard to the flow régime are (1), The wetting front is sharply defined and the water pressure is known at some point behind the wetting front, and (2) the soil moisture content behind the wetting front does not change appreciably with time and is close to saturation

If Q is the volume flow per unit time out of the cavity, then as the wetting front moves radially outward·

$$Q = S4\pi r^2 \mathrm{d}r/\mathrm{d}t \qquad (1)$$

where S is the change in moisture content expressed as the volume of water change per unit volume of soil The $4\pi r^2$ term represents the circumferential area of the wetting front and this is multiplied by $\mathrm{d}r$ to give the volume of soil An alternative expression for the flow can be obtained by a consideration of the pressure distribution around a spherical source. The equation for the flow per unit time is given by:

$$Q = [k4\pi(p_w - p_c)]/(1/r_w - 1/r_c) \qquad (2)$$

Setting these two equations equal and solving for the hydraulic conductivity k, we have, after introducing the boundary conditions

$$k = [1/(t_2 - t_1)][(1/3)S(r_2{}^3 - r_1{}^3)/r_w(p_w - p_c)] - 1/2[S(r_2{}^2 - r_1{}^2)/(p_w - p_c)] \qquad (3)$$

where p_c is the pressure head behind the wetting front, p_w is the average pressure head in the cavity, r_w is the equivalent radius of the cavity and $t_2 - t_1$ is the time required for the wetting front to travel from r_1 to r_2

The above equation is used to calculate the hydraulic conductivity following the procedure outlined below Two measurements are needed the rate of flow from the cavity and the time for the wetting front to move from r_1 to r_2 as shown in Fig 1 The change in moisture content, S, is calculated by $S(r_2 - r_1) = Q(t_2 - t_1)/(4\pi r^2)$, where r is taken as the average of r_1 and r_2 The progress of the wetting front from r_1 to r_2 is measured electrically.

A laboratory experiment was performed to test the validity of the assumptions used in the development of the theory The experiment was performed in a sector tank filled with a Columbia fine sandy loam soil Pressure measurements were made with tensiometers located at various points in the tank The results of the tank measurement indicate that the assumptions are reasonable and the values of hydraulic conductivity obtained in the tank indicate that the method can be used to get an approximate value of hydraulic conductivity in the field

The method is at present being developed in the field and as additional information is obtained a further report will be made

Nature of Sulphate Retention by Acid Soils

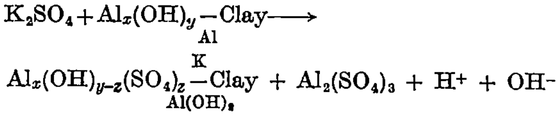
Certain soils containing oxides which occur in tropical and subtropical regions are known to retain an appreciable amount of sulphate when equilibrated with dilute solutions of sulphate salts[1,4] In our earlier work we found that the cation and anion are held in about equivalent amounts, with an increase in retention occurring as the pH was lowered or the sal concentration was increased So far as we are aware no satisfactory explanation for all the phenomena observed has yet been given

Recently we have found that the amount of sulphate which is held by an acid red soil increases with time of equilibration up to eight weeks (the longest period studied) Sulphate was added as K_2SO_4 and the amount retained was measured in two ways In the first, the K_2SO_4 was labelled with sulphur-35 and its disappearance from solution was recorded In the second, the cations in solution were measured and their sum assumed to be equal to the sulphate in solution The first method has the disadvantage that isotopic exchange with native soil sulphate occurs and makes the results higher than the true values The second suffers from lack of precision Taken together, however, they show about the same trend in the retention of sulphate with time As can be seen from Table 1, the greatest increase in sulphate held occurred during the first 24 hr

Table 1 EFFECT OF TIME ON THE RETENTION OF SULPHATE FROM 0 01 N K_2SO_4 BY CECIL SOIL

Equilibration time	Sulphate retained (m equiv /100 gm) By sulphur-35	By cation sum
1 hr	1 50	0 42
24 hr	2 20	1 74
1 wk	2 40	2 04
2 wk	3 24	1 92
4 wk	3 60	2 02
8 wk	—	2 38

It has been found[3] that the hydrolysis of exchangeable aluminium and the formation of hydroxy-aluminium compounds proceeds at a greater rate in soil systems to which a salt has been added In acid red soils the sulphate can exchange with some of the hydroxyl ions on the hydroxy-aluminium (or iron) polymers The overall reaction is described as follows



$$K_2SO_4 + Al_x(OH)_y\underset{Al}{-}Clay \longrightarrow$$

$$Al_x(OH)_{y-z}(SO_4)_z\overset{K}{\underset{Al(OH)_2}{-}}Clay + Al_2(SO_4)_3 + H^+ + OH^-$$

The replacement of hydroxyl groups from the hydroxy-aluminium groups results in the neutralization of hydrogen ions from the hydrolysis of exchangeable aluminium Similar reactions also occur with salts of chloride and nitrate

A reaction of this general form explains the increase in sulphate retention with increasing concentration and decreasing pH since under both these conditions hydroxyl ions would be replaced more easily The increase in retention of sulphate with time is explained by the hydrolysis of exchangeable aluminium to a dihydroxy-aluminium species[2] and the subsequent neutralization of the hydrogen ions thus formed by replaced hydroxyl ions This reaction provides sites on which both potassium and sulphate ions can be held

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 7 p m —Scientific Papers

Thursday, November 2

Royal Society (at Burlington House, Piccadilly, London, W 1), at 10 30 a m —Discussion on "Mechanisms of Virus Infections" opened by Prof Wilson Smith, F R S

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr J L Watling "Probability" *

Chemical Society (at Queen Mary College (University of London), Mile End Road, London, E 1), at 2 p m —Symposium on "Electron-spin Resonance".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Prof J J Pritchard "Bone Healing" * (Sixth of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

University College, London, and the Feldberg Foundation for German-English Scientific Exchange for Experimental Medical Research (in the Physiology Theatre, University College, Gower Street, London, W C 1), at 5 30 p m —Prof Herbert Hensel (University of Marburg) "The Electrophysiology of Thermoreceptors" * (Feldberg Foundation Lecture)

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 6 p m —Mr T Somerville "Acoustics and the Electrical Engineer"

Institute of Refrigeration (joint meeting with the Refrigeration Servicemen's Association, at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Borough Polytechnic, Borough Road, London, S E 1), at 7 p m —Mr J E Kumler "Modern Designs in Thermostatic Control for Refrigeration, including Air-Conditioning, Automatic Defrosting and Heat Pump Applications"

Royal Institute of Chemistry (joint meeting with the Brunel College of Technology Chemical Society, at the Brunel College of Technology, Woodlands Road, Acton, London, W 3), at 7 p m —Dr J Lewis "Modern Developments in Co-ordination Chemistry".

Friday, November 3

Mineralogical Society, Clay Minerals Group (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 11 a m. —Autumn meeting

Institute of Physics and Physical Society, Colour Group (joint meeting with the London Section of the Society of Dyers and Colourists, at Burlington House, Piccadilly, London, W 1), at 6 p m —Mr K MacLaren "A Daylight Illuminant"

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W C 2), at 6 p m —Discussion on "Information Theory in Relation to Biology" opened by Prof D M Mackay

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Prof B Lythgoe "The Wittig Reaction and its Application in Organic Synthesis"

Royal Institution (at 21 Albemarle Street, London W 1), at 9 p m —Dr S Brenner "The Handing on of Genetic Information in Living Matter"

Saturday, November 4

Association of Clinical Biochemists, Southern Region (at Queen Mary's Hospital, Roehampton, London, S W 15), at 2 30 p m. —Symposium on "Special Applications of Electrophoresis"

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Mr Frank W Lane "Kingdom of the Octopus" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant in Biochemistry in St Salvator's College—The Secretary, The University, College Gate, St Andrews (November 4)

Lecturer, Grade I (preferably with experience in the biochemistry of proteins or nucleic acids) in Biochemistry—The Registrar, The University, Leicester (November 4)

Lecturer (with a good degree in zoology, and preferably research experience) in Zoology—The Bursar, College of Advanced Technology, Gosta Green, Birmingham 4 (November 4)

Lecturers (honours graduates in engineering or in science), to teach the subject of applied thermodynamics to students of engineering—The Secretary of University Court, The University, Glasgow (November 7)

Assistant Lecturer or Lecturer (preferably with a special interest in Africa) in Geography—The Secretary, University College, Gower Street, London, W C 1 (November 10)

Assistant in Genetics—The Secretary of University Court, The University, Glasgow (November 10)

Lecturer (veterinary graduate with a special interest in the field of reproduction) in the Department of Animal Husbandry at the Veterinary Field Station, Langford, near Bristol—The Registrar and Secretary, The University, Bristol (November 11)

Superintendent (with administrative experience, and preferably some scientific experience) of the University Biochemical Laboratory—Prof F G Young, Department of Biochemistry, The University, Tennis Court Road, Cambridge (November 16)

Lecturer in the Electronic Computation Laboratory of the Applied Mathematics Department—The Registrar, The University, Sheffield (November 18)

Lecturer or Assistant Lecturer (with a good honours degree or equivalent in engineering, physics or mathematics and some research experience) in Vibration Theory—The Secretary and Registrar, The University, Southampton (November 18)

Botanist (with a degree, preferably majoring in botany, non-graduates with a knowledge of taxonomy and herbarium experience may be considered) in the Botanic Garden Department, Adelaide, South Australia, for general herbarium, duties, determination of plants, and the supervision of botanical assistants—The Agent-General and Trade Commissioner for South Australia, South Australia House, 50 Strand, London, W C 2 (November 20)

Wykeham Professor of Physics—The Registrar, University Registry, Oxford (November 23)

POSTDOCTORAL RESEARCH FELLOW IN ORGANIC CHEMISTRY at the University of Melbourne—The Registrar, University of Melbourne, Parkville, N 2, Victoria, Australia (November 25)

LECTURER (with postgraduate qualifications and research interests in experimental or social psychology) **IN PSYCHOLOGY** at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, November 27)

CHAIR OF PATHOLOGY in the Medical School, University College of Rhodesia and Nyasaland, Salisbury—The Registrar, University of Birmingham Edgbaston, Birmingham 15 (November 30)

CHAIR OF PHYSIOLOGY in the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 30)

LECTURER (with a degree in electrical engineering from a British university, or equivalent, preferably with first- or second-class honours, corporate member of the Institution of Electrical Engineers and preferably with experience in teaching at university level and/or of research work) **IN ELECTRICAL ENGINEERING** at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Hong Kong and London, November 30)

PROFESSOR OF EXPERIMENTAL PHYSICS—The Registrar, The University, Nottingham (November 30)

REGIUS CHAIR OF SURGERY in the University of Aberdeen—The Private Secretary, St Andrews House Edinburgh 1 (November 30)

SENIOR LECTURER/LECTURER IN BOTANY, a **SENIOR LECTURER/LECTURER** (preferably with qualifications in inorganic chemistry) **IN CHEMISTRY**, and a **SENIOR LECTURER/LECTURER IN MATHEMATICS** at the University of Khartoum—The Registrar University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (November 30)

LECTURER (preferably with experience in teaching, research and in the design and construction of hydraulic works and apparatus) **IN CIVIL ENGINEERING** (Hydraulics) at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall London, S W 1 (December 1)

BURNETT-FLETCHER CHAIR OF HISTORY AND ARCHAEOLOGY—The Secretary, The University, Aberdeen (December 9)

RESEARCH ASSOCIATE (with a Ph D in chemistry or physics) **IN SPECTROSCOPY**, for research in the field of chemical aspects of electron paramagnetic resonance spectroscopy—Industrial Engineering Services Research Council of Alberta, 87th Avenue and 114th Street, Edmonton, Alberta, Canada (December 15)

SENIOR LECTURER (with an honours or higher degree in science or engineering, and teaching and/or research experience in the field of physical metallurgy) **IN PHYSICAL METALLURGY** at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (December 15)

VISITING PROFESSOR OF OCEANOGRAPHY at the University of Cape Town, South Africa—The Secretary Association of Universities of the British Commonwealth (Branch Office), Marlborough House Pall Mall, London, S W 1), and The Registrar, University of Cape Town Private Bag, Rondebosch, Cape Town, South Africa (December 31)

ASSISTANT EXPERIMENTAL OFFICER (with a pass degree in biology (including zoology), F I M L T or equivalent qualifications, and preferably some experience in histological techniques) **IN THE PHYSIOLOGY DEPARTMENT**, to assist with histological investigations related to the endocrine research programme of the Department—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield Reading, quoting Ref 61/22

ASSISTANT LECTURER (Grade B) (with a degree or equivalent qualifications, teaching experience, able to teach to higher national certificate standard, and preferably some industrial experience) **IN CHEMISTRY AND METALLURGY**—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex

ASSISTANT PROFESSOR (with two or three years postdoctoral experience in a field allied with virology, and prepared to participate in a research programme on the virology of tumours) **ON CANCER RESEARCH**—Dr R Bather, Department of Cancer Research, University of Saskatchewan, Saskatoon, Saskatchewan, Canada

FISHERIES OFFICER (male, qualified biologist, with an honours degree in natural science, preferably zoology, and experience in research work) in Tanganyika, to investigate the ecology of inland waters in relation to fish production—Director of Recruitment, Department of Technical Co-operation, Carlton House Terrace, London, S W 1, quoting BCD 63/8/012

GRADUATE (with a degree in a biological science and an interest in cytogenetics) **IN THE BIOPHYSICS SECTION**—The Administrator, Radiobiological Research Unit, Medical Research Council, Harwell, Didcot, Berks

LECTURER or **SENIOR LECTURER IN CHEMISTRY** in the Training Department—The Warden, University of London Goldsmiths' College, New Cross, London, S E 14

RESEARCH FELLOW IN ORGANIC CHEMISTRY—Prof R C Cookson, Chemistry Department, The University, Southampton

RESEARCH FELLOW or **ASSISTANT** (with a good honours degree in mathematics or engineering and preferably experience in programming for a digital computer) **IN THE DEPARTMENT OF AERONAUTICS AND ASTRONAUTICS** for work in the field of hypersonic gas dynamics—The Secretary and Registrar, The University, Southampton

SECRETARY (with administrative experience in a responsible capacity in university of equivalent posts) of the College and Clerk to the Governors—The Rector, Imperial College of Science and Technology, South Kensington, London, S W 7

STATISTICIAN (graduate) **AT THE RADIOBIOLOGICAL UNIT** of the Medical Research Council, for work which includes a wide variety of physical and biological problems—The Administrator, Radiobiological Research Unit, Medical Research Council, Harwell, Didcot, Berks

TECHNICIAN or **SENIOR TECHNICIAN** (with general biochemical laboratory experience and a knowledge of electronics), for duties involving assistance with research and occasional classwork and maintenance of spectrophotometers, high speed centrifuges, etc—The Secretary, University College, Gover Street, London, W C 1 quoting "Biochem /1"

TECHNICIAN (Scientific Assistant grade) (preferably with experience of tissue culture methods), for work on respiratory diseases of animals—The Administrative Secretary, School of Veterinary Medicine Madingley Road, Cambridge

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Bulletins of Marine Ecology (formerly *Hull Bulletins of Marine Ecology*) Edited by Sir Alister Hardy, Dr C E Lucas and R S Glover No 43, Vol 5 The General Hydrography of the Clyde Sea Area, Scotland Part 1 Description of the Area , Drift Bottle and Surface Salinity Data By Dr H Barnes and the late E F W Goodley Pp 112–150 11*s* No 44, and 45, Vol 5 The Multi-Depth Plankton Indicator By R S Glover A Modification of the Small Hardy Plankton Sampler for Simultaneous High Speed Plankton Hauls By David Miller Pp 151–172 6*s* 6*d* (Edinburgh Scottish Marine Biological Association, 1961) [258

A NATIONAL YOUTH SCIENCE PROGRAMME

RECOGNIZING the great strides being taken by science to-day, the fact that, according to Sir Bernard Lovell, of all the scientists who ever lived 90 per cent are with us to-day, and, above all, universal acknowledgment of the fact that all and sundry are now in some way or another responding to the impact of science on themselves and on society (whether conscious of it or not), one must admit that there is need for everybody to learn something about what is behind this great and rather sudden social upheaval

Science yields power it renders physical power to industry and travel, further means of interpretation in the various arts, more facilities for enjoying one's leisure, but it is to be hoped that it will never succeed in giving power to the few who might use it for controlling the many Yet that risk seems very real to-day, due mainly to the widespread lack of understanding of the true aims and objectives of science As Mr Dean Rusk recently said ' Power is not a matter of arms alone Strength comes from education, fertile acres, humming workshops and the satisfaction and pride of peoples". Strength assuredly comes with education, and in this science must play a much greater part from the earliest years of a child's life This has also been emphasized recently by Lord Hailsham, the Minister for Science (see p 393 of this issue)

For many years one referred to pure science and applied science, this eventually being altered to fundamental and applied science Gradually it has become recognized that there is no hard and fast line of demarcation between the two—that one inspires the other, and that fundamental science is not entirely basic to applied science and vice versa To-day, one hears of science and technology, perhaps the day is not far off when the implied distinction between these two will disappear Accepting, perhaps with some reservation, Murray Schoonraad's statement that "to-day's science is to-morrow's technology" (*Nature*, **191**, 848, 1961), it would seem that there is no real distinction between science and technology, but that over a period of time one merges into the other and that the length of this period is quickly becoming shorter Science should eventually, therefore, be recognized for what it really is, namely, the search for the truth (using its own peculiar means), the exposition of the truth and its application wherever possible to man's needs and comforts

The 'balance of power' periodically changes even within the ranks of the scientists themselves, such changes being inspired by popular appeal or curiosity or sudden recognition of profitable application For example, in the Victorian era, Darwin and his supporters stirred the world with the conception of the origin of species As these ideas appeared to strike at the very roots of the religious faiths and beliefs of millions of people at that time, one can easily imagine how science (in this case, biology) was brought to the foreground in public debate, discussion and sometimes heated argument as exemplified by the Huxley–Wilberforce contretemps at Oxford and, much later the growth of so-called Fundamentalism in the United States which, starting as a denominational interest, eventually became a national concern when, in 1925, a teacher in Dayton, Tennessee, was tried and convicted for teaching the principles of evolution in a State school Thus, for a time, science made a spectacular appearance before a world-wide audience

One can think of other scientific spectacles, those of to-day obviously being feats in space science But such spectacles can sometimes do more harm than good to science itself, for it would be undesirable to have a scientific *élite* in any community, such as is now developing in the U S S R Science is actually proceeding on a very broad front, and many of its facets, highly important though they are, can never be spectacular So it can be only a very small majority of people who recognize this general advancement, and, to-day, no one person can be expected to understand all of it. Even now it would be a very small percentage of those who have not read biology to a fairly advanced level in school who could give the names of the scientists who discovered penicillin or insulin So clumsy is the way in which science is presented to the public that it is unlikely that Fleming's name will ever become such a household word as that of Gagarin Macromolecular biology is now making great strides in the field of scientific endeavour, but it will be some time before the non-scientist will be able to understand and appreciate this

This does not imply that all thinking people are not aware of the need for a much wider and deeper appreciation of science and its impact on human society The main problem is how to set about it It seems better to acknowledge the fact that among adults only those who wish to know something about this 'Age of Science' will take the trouble to learn This minority is fairly well catered for already In Britain, the British Association for the Advancement of Science, the Workers' Educational Association, the extra-mural departments of the universities, many local authorities, the British Broadcasting Corporation and television authorities are doing excellent work to enlighten those who wish to learn

This is by no means enough, for it is not only the mature grounds which need attention but also the newer, uncultivated yet potential fertile soil—men and women of to-morrow, who are recognizable as soon as they are able to speak

Governments, local authorities, industry, etc , are bringing pressure to bear in an all-out attempt to increase, widen and improve the standards of science teaching In some cases, no doubt, the results are proving disappointing and mediocre, this being due to many conditioning factors, the chief of which is the dearth of science teachers, unsuitability of some of these, lack of space and equipment, finance, and so forth, but above all the time-factor in school terms and hours.

Science teaching seems to have become too rigid, especially in its attitude towards the applications of science. This may be due to a schism in thinking of science as a cultural discipline in contradistinction to science as a practical need. (The examination systems may be largely responsible for this.) Heuristic methods of teaching, as practised and advocated by H. E. Armstrong earlier in this century, served a useful purpose at the time in that they pointed the way to an effective means of teaching the scientific method of experimentation. But such methods aim largely at training potential scientists, and though they inspire some children who have no intention of becoming professional scientists they might well repel others. They are, therefore, not entirely satisfactory if we are to capture the imagination of the majority of the very young in the appreciation of science. The practical application of *A* to *B* may not be so interesting as the application of *A* to self, for what touches the heart of the layman is the effect scientific progress is having on himself—that is, the practical applications of science to man, his health, his job, his creature comforts and, above all, his future. The laboratory is not the only room where science can be taught: it is not necessary to dissect a rabbit in order to learn about the bones of the mammalian skeleton, neither is it necessary to use earthworms with the ancillary apparatus to understand about respiration in animals. Many observations and experiments can be carried out on the pupil's own body, thus becoming more interesting. None of this need undermine the ultimate aim of treating science for what it is, namely, a cultural, and therefore not solely a technical, discipline.

Where, therefore, are the other and earliest grounds for successful scientific seeding? When does a child reach the critical point when he might become inspired with things scientific? The first lies within the ægis of the primary school (many of which have no laboratory), and the second depends on how successful is the seeding in the first. It was with the view of considering how the initial seeding could best be accomplished that the British Association for the Advancement of Science convened a conference, during September 29–30, jointly with the Association of Teachers in Colleges and Departments of Education, on "The Approaches of Science in the Primary School".

At this conference, Mr. N. Isaacs said that the "approaches" in this case are through a disciplined way of thinking, a way encouraged by a definite method of exploration of the physical, biological and psychological worlds. The natural learning processes of the child are akin to the development of scientific thinking—exploration, collecting and piecing together experiences, building up these into a connected scheme of knowledge and foresight. Such processes can be observed in the developing child, and become most marked when the child, in its third or fourth year, has sufficiently mastered language to discover the way of question-forms. The method of seeding should be one of accentuating and directing the natural learning process. This would, it is hoped, be achieved by creating in the primary schools specific environments aimed at developing the individual's interest by setting the scene, catching his innate curiosity and spurring him on to observe and bring forward the right kind of question and hence an attitude to exploration. So, by the time he enters the secondary school, the child is competent to know his world, capable of planning and ready for things scientific. Given an interest in science he will need nothing but opportunity to develop it. However, unless the child is deeply and naturally instilled with the human implications of his knowledge in the primary school, his approach to science teaching in the secondary school will not be satisfactory.

Much more can be done also outside school hours. A great deal has already been done in the United States in this highly important field of extra-mural endeavour. By 1940 some seven hundred 'science clubs' had been founded there. The movement was somewhat retarded by the Second World War, but the project gained momentum during the post-war years, and now there are about 25,000 science clubs of which approximately 500 are outside the United States. Through what is termed 'Talent Searches' individual boys and girls showing special aptitude are encouraged, and it is now claimed that 95 per cent of those winning honours in the Science Talent Search proceed to the universities. According to Science Service's *Growth of the Science Youth Program* (October 10, 1959), honours were awarded to about 10 per cent of the entries and about 50 per cent of these eventually gained doctorates. Yet it is to be hoped that those who were not so selected are now progressing through life with a better understanding of science than they would otherwise have had. If so then Science Service (Washington) is doing excellent work. This Service also inaugurated 'Science Fairs', first on a local and regional basis. By 1950 these had become so numerous that the National Science Fair was instituted. In 1958 this Fair became international through the entry of finalists from Japan's National Fair.

This project could well be followed elsewhere, as indeed it is in Britain, though two other methods of somewhat similar pattern might be considered. First, a central organization might be set up to encourage and direct the attention of science teachers to possible extra-mural activities aimed at young children and teenagers in most branches of science—astronomy, the physical sciences, archæology, natural history, engineering, agriculture, horticulture and so forth. Such an organization might invoke the aid and advice of national and local scientific societies. Thus it should be possible to encourage school teachers to become more flexible in their teaching by organizing extra lectures and exhibitions, and above all, by making available opportunities for practical work during term-time at specific centres.

These activities might, though not necessarily, be divided into age-groups, but should on no account be confined to those pupils who are aspiring to the science sixth form

It can be taken for granted that, once established, such a scientific centre would be able to rely on much practical assistance from local industry, though that would depend considerably on the personality and tact of those running the centre In any event, the time seems ripe for academic and industrial research centres to open up their laboratories, workshops and even factories more often than they do for organized visits by school children Museums play their part, but this is not enough Of course, a great deal is already being done, but much more is needed, for this will help to inspire interest among the many who may never become professional participants in future years, and it must be recognized that these are the laymen of the future so far as science is concerned

Certain sections of industry actually do arrange campaigns, and send their representatives to schools and universities, but their object is clearly to catch the future scientists, and in any event they, and others, might do still better by 'selling' themselves on their own premises rather than in the school lecture theatre

A second method of approach takes into account the fact that it is asking a great deal of any school teacher to take on still further responsibility, especially out of school hours, terms or grounds Yet much could be done, as in the Boy Scouts and Girl Guides movements, that is, not only outside school hours but also away from the daily school teacher with all due respect to him, a change of senior personnel might prove stimulating

The British Association is doing much towards educating youth During the recent annual meeting at Norwich there were three young people's lectures, a schools exhibition, the President's tea party for student exhibitioners and the annual session devoted to "Science in the Sixth Form" organized by Section X This is good and points the way to further endeavour with still younger children in view Nevertheless it must be recognized that such events are confined to a few days each year, to the comparatively small number of large towns and their catchment areas and to a fairly advanced age-group With its lecture services, young people's programmes, international youth science conferences, area committees, science fairs, etc , the British Association has made increasing and comprehensive contributions to the development of more widespread scientific education But it would be a greater step forward if such a body as the British Association made a survey of the needs and potentialities of the whole country, for there is much to be found—the entire country is not lying fallow There are numerous local scientific societies, many of them, it is true, confining themselves to natural history and archæology, but there they are, and some have junior sections Then what always seems to be overlooked is the fact that there are many individual enthusiasts and sometimes small groups of enthusiasts who are interested in a very practical way in most branches of science It is often stated that the days of the 'amateur' scientist are gone, but we believe this is far from the truth It was Will Hay who made very important contributions to astronomy using his 6-in Cooke refractor mounted in his home-made observatory, and by profession he was a stage and screen actor We believe there are many of his type, in various scientific disciplines, cultivating their interests to-day

Most of these local societies, clubs, and individual enthusiasts appear to depend mainly on themselves Yet it is they who might be prepared to form the nuclei for still further local endeavour with the young as their main objective They might well take into consideration the lines of approach suggested by Sir Eric Ashby in his British Association Granada Lecture in 1960 He proposed that an understanding of science could be imparted by emphasizing the importance of technique in science, for the ordinary man is a craftsman and he appreciates craftsmanship. This might well be extended to the children and youth of to-day

Such local individual and collective movements might be loosely unified under a sponsoring body such as the British Association, which is not only well equipped with the necessary contacts but also has the nucleus of the necessary staff Such a sponsoring body, set up on a national scale but using and inspiring local men and women, could offer to the boys and girls of Great Britain the encouragement in scientific activity and appreciation that the National Playing Fields Association, with the invaluable patronage of the Duke of Edinburgh, is giving them in sport and recreation

ELECTRODYNAMICS AND MECHANICS

Electrodynamics of Continuous Media

By L D Landau and E M Lifshitz Translated from the Russian by J B Sykes and J S Bell (Course of Theoretical Physics, Vol 8) Pp x+417 (London and New York Pergamon Press, 1960) 84s net

Mechanics

By L D Landau and E M Lifshitz Translated from the Russian by J. B. Sykes and J S Bell (Course of Theoretical Physics, Vol 1) Pp vii+165 (London and New York· Pergamon Press, 1960) 40s net

THE titles of the volumes in this series cover a vast range of topics and there seems to be little in physics on which the authors are not very well informed The volume on electrodynamics conveys a sense of mastery of the subject-matter on the part of the authors which is truly astonishing I myself have read only one other volume of the series and cannot lay claim to any specialized knowledge of any of the topics dealt with These remarks, therefore, cannot criticize any details of the physics discussed in this volume

The broad lines adopted by the authors become clear very quickly Maxwell's equations are assumed to hold on a microscopical scale and all macroscopical results are derived by a process of taking averages. Forces and energy relations are obtained by a systematic use of the concepts of thermodynamics—there is no place here for the transport of current filaments from infinity and similar 'elementary' devices. The ambiguities of sign sometimes associated with energy expressions are firmly resolved and all such quantities put into their proper perspective as thermodynamical quantities. But such matters are not the chief concern of this volume.

With the help of straightforward ideas of symmetry, linear dependence (and contour integration) the basic ideas of electromagnetism are developed to apply to a long list of topics. These include electrostriction, piezoelectricity, ferroelectrics, the Hall effect, contact potential, electrocapillarity, thermoelectricity, gyromagnetism, ferromagnetism, superconductivity, eddy currents, the skin effect, magnetohydrodynamics, dispersion, wave-guides, double refraction, etc. This list is by no means complete. The standard of explanation is admirable, being sufficient to give a moderately informed reader a grasp of the principles concerned, both physical and theoretical, without elaborate detail. The approximations which must be made to make a theoretical treatment feasible are explained and the theory developed starting from the field equations in most cases. It is the physical insight which accompanies and guides this development that conveys the sense of mastery mentioned here.

To-day the division of the subject-matter of physics into heat, light, sound and properties of matter is being superseded; this book will accelerate this change. In fact, one of the impressive features of the book is the way in which diverse phenomena, listed above, are shown to be related through the dependence of ε (permittivity), μ (permeability), or σ (conductivity) on the frequency of the radiation. Phenomena, which in elementary physics are explained by a closed and mathematically elegant theory, here appear related as a result of expanding ε, say, in terms of the frequency. The general effect is to demonstrate the full power and generality of electrodynamic theory in a way seldom achieved in a textbook.

The translators are to be congratulated on the effectiveness of their translation; the language is direct and could well be original English text. There are surprisingly few typographical errors, about a dozen were noticed, most of these being the omission of a letter or a symbol. Throughout the volume there are references from time to time to modern work, mostly in Soviet journals, a large proportion being available in translation. In short, *Electrodynamics of Continuous Media* is a book which can be thoroughly recommended to every physicist.

In the history of science it has always required a great intellectual effort to break free from established modes of thought and to establish a new outlook, exemplified in the change from the Ptolemaic to the Copernican view of the universe. To-day we are in the midst of a similar change with the advent of modern physics, and the volume on mechanics will contribute to the establishment of a new outlook.

Although the subject-matter is, of course, Newtonian mechanics, the basic outlook is different from the traditional Newtonian outlook. From the outset Hamilton's Least Action Principle is taken as the fundamental law governing all motion; an inertial frame is one for which space and time are isotropic and homogeneous, and the basic transformation is the Galilean transformation between two inertial frames. Considerations of symmetry lead to the law of inertia, and the equivalence of two inertial frames leads to the introduction of a coefficient identified as the mass of a particle. A system of particles which interact with one another but with no other body requires an addition, $-U$, to the sum of the Lagrangian functions of the particles to give the Lagrangian of the whole system. This function U, depending on the co-ordinates only (non-dissipative systems only ?) is the potential energy. There is no indication of how to find the form of U in any given case. The use of the equations of motion now introduces the concept of a force and we arrive at Newton's Second Law of Motion. Throughout this part one feels that without the familiarity gained from the traditional outlook and the associated intuitive appreciation of mass, force, etc., it would be difficult to appreciate the proper significance of many of the results. In some of the succeeding chapters these intuitive ideas are still necessary to 'feel what is going on'—the escape from traditional views is not complete.

On one point of the dynamics of a rigid body the treatment is not quite satisfactory. On p. 109 it is said that the equation for the rate of change of angular momentum "May be regarded as Lagrange's equation . . . for the 'rotational co-ordinates' ". Apart from the inverted commas it is not pointed out that there are no such co-ordinates, that a component of angular velocity is not, in general, the rate of change of any one angle, as is shown afterwards in equation (35.1). This topic should, strictly, be treated as a non-holonomic constraint according to the methods of a subsequent section. Nevertheless, this is a familiar point and the reader already knows the results. It does not affect anything else in the book.

When the reader has adjusted himself to the new outlook then the rest of the book, the greater part, is a vindication of the effort of making this adjustment. The scope and power of the methods used are made abundantly evident in fields of importance to physicists; little time is spent on artificial classical problems. The theory of collisions between particles is developed in a form in which physicists need it; this is followed by chapters on small oscillations, the motion of a rigid body, and finally Hamilton's equations, Poisson brackets, Liouville's theorem, Hamilton–Jacobi equation, etc. This last chapter lays the foundations for the transition to quantum mechanics.

In undergraduate courses on dynamics the treatment of small oscillations often leaves the impression that the theory is self-contained without room for development. Here it is clear that the familiar theory is one stage in the approximations necessary for the discussion of such motions. The development to anharmonic and non-linear oscillations follows naturally. This is typical of the way in which the reader is shown that classical mechanics is still capable of development. The illustrative problems are very carefully chosen and the accompanying solutions are admirable for conciseness, the salient points only being given.

It is a remarkable achievement to write a text on advanced analytical dynamics in the compass of 165 pages and to produce such a stimulating account. The translation is excellent and errors of typography are very few and far between.

A STUDY OF DIABETES

Diabetes in an English Community

A Study of Its Increase and Natural History By Joan B Walker and David Kerridge Pp 46. (Leicester The University Press, 1961) 7*s* 6*d*

A VALUABLE survey of the incidence and natural history of diabetes in a rural parish (Ibstock in Leicestershire) has been made by Dr Joan Walker of Leicester Royal Infirmary and David Kerridge of the University of Sheffield

The inquiry was initiated in 1955 by the British Diabetic Association in an attempt to arrive at a numerical evaluation of the problem of diabetes in Britain The figures available from the General Register Office vary from two to four diabetics per thousand of the population, but these figures refer to known diabetics It was well known from the United States and Canada that, in previous surveys, as many unknown diabetics were found as those already diagnosed

Many of the methods used by other investigators depended on the study of clinics, schools, factories, prisons and other such institutions, which are special groups with age and sex selection, while detection drives, although not restricted to special age or occupation groups, depend on voluntary initiative and tend to have low response-rates, and therefore allow too much room for bias Throughout the year 1956, these ways of determining the incidence of diabetes in Britain were discussed It was essential to find a method which would be practical, easily applied elsewhere, and be, at the same time, accurate. It was agreed that no census of known diabetics attending clinics could produce the information required As it was most important for the purposes of the investigation that follow up should be possible, it was finally decided to investigate a compact stable community

Because the diabetic clinic at Leicester Royal Infirmary served the City and whole County of Leicestershire, and because some of the Leicestershire villages had exceptionally static populations, it was decided to investigate a village community with the view of its becoming part of any larger national or international survey which might be undertaken later

The objectives of the inquiry were as follows· to establish the number of diabetics in a natural area where the population is static, to discover the undiagnosed cases of diabetes, to investigate the possible hereditary factors; to investigate the possible ætiological factors of physique, diet habits, stress. occupation, and parity in women, to follow up the cases of glycosuria discovered by the investigation, if possible, for as long as twenty years, and to watch for new cases developing in the area, to repeat the whole survey at a future date and to repeat it also in another area of England for comparison or contrast.

Every person living in the village who was over the age of five years was asked to supply a specimen of urine and to answer a questionnaire Altogether 2,071 males and 2,034 females were tested making an 81 per cent response of the population over the age of five years Details of thirty-three previously diagnosed cases were collected from general practitioners' and clinic records So far as could be determined the 19 per cent of non-co-operators were not different in age or other environmental factors from the rest, and in calculating rates, it was assumed that they were a random sample of the whole population

The results show that there are about thirteen diabetics per thousand of the population, half of whom are asymptomatic The relationship of diabetes to various social factors was examined. Plans for a follow-up study of the population are also described in the booklet

ANALYTICAL INSTRUMENTATION

Physical Methods in Chemical Analysis

Vol. 1 Edited by Walter G Berl Second Edition Pp xiv+686 (New York Academic Press Inc , London Academic Press Inc (London), Ltd , 1960) 19 dollars

ADVANCES and refinements in analytical instrumentation must, of necessity, call for periodic reviews of those publications which form such an essential part of that ever-expanding physicochemical noosphere from which the modern scientist draws both inspiration and knowledge This present revision (Volume 1) of a well-known authoritative treatise on instrumental methods in chemical analysis belongs to this category

The more elementary student may find the advanced and detailed form of presentation somewhat bewildering, but as his knowledge increases and he joins the ranks of the experts, he will undoubtedly appreciate the lucidity with which the various specialist contributors have described those practical and theoretical problems which are concomitant with the complex field of contemporaneous instrumentation This is, however, a book which has been written by experts for experts, and, at the academic stage, it will undoubtedly be of the greatest assistance to honours graduates and research workers Most modern instrumental methods are described with much attention to practical laboratory detail Nearly a quarter of the 670-page work is devoted to X-ray diffraction techniques as applied to powders, metals and polymeric fibres Spectrophotometry, emission spectrography and infra-red spectroscopy are given comprehensive treatment in chapters of about 80 pages each The diagrammatic illustrations are clear and well annotated and each chapter concludes with an extensive bibliographical reference section

Later sections deal with Raman spectra, measurements of refractive index, mass spectrometry, and electron microscopy and diffraction The latter technique is particularly valuable for those crystallographic investigations on surfaces where the affected layer is too thin to be detected by X-rays The section on electron microscopy gives some extremely interesting reproductions of electron micrographs of films of various materials

The applications and design of simple and tandem mass spectrometers are described in some detail. Reference is made to the usages of such instruments in the analysis of chemical mixtures, the leak-testing of evacuated vessels, measurements of appearance potentials and related thermal quantities, reaction kinetic studies, etc.

This new edition undoubtedly provides up-to-date information on progress in the development and application of physical instrumentation and will be eagerly acquired by all chemists having an interest in the theory and practice of these specialized analytical techniques D T LEWIS

Materials for Nuclear Engineers

Edited by Dr A B McIntosh and T J Heal Pp ix+373 (London Temple Press, Ltd, 1960) 75*s* net

WRITTEN by specialists on the United Kingdom Atomic Energy Authority staff, this handbook on nuclear materials should prove invaluable as a reference volume not only to nuclear engineers but also to many scientists and technicians working in the nuclear power field The materials covered are uranium, plutonium and thorium metal fuels, together with their more useful ceramic compounds magnesium, beryllium and zirconium canning materials and graphite as the most important solid moderator The occurrence, extraction, fabrication, physical and mechanical properties, compatibility in various reactor environments and behaviour under irradiation are discussed for each material The data are presented in suitable tabular and diagrammatic form and have been selected as the best available from published information to mid-1959

It is regrettable that space could not be found to include stainless steel canning materials, ferritic steels which are of current interest for pressure vessels, and beryllia, which is the most promising alternative solid moderator to graphite, particularly for high-temperature gas-cooled reactors Equilibrium diagrams are given for sixteen plutonium alloy systems and it would be valuable to have diagrams also included for the technologically important alloys of uranium and thorium

As this is a rapidly expanding field, new or revised data, especially on the irradiation behaviour of fuels, are continually forthcoming, and it is to be hoped that suitably revised editions will be produced in good time In particular, the nuclear engineer will need to be kept up to date on the progress of ceramic and cermet fuels which are becoming of increased importance

Neuro-Psychopharmacology

Proceedings of the First International Congress of Neuro-Psychopharmacology, Rome, September 1958 Edited by P B Bradley, P Deniker and C Radouco-Thomas Pp xv+727 (Amsterdam Elsevier Publishing Company, London D Van Nostrand Company, Ltd, 1959) 135*s*

THOUGH neuropsychopharmacology might be shortened as a word, the book deserves no shortening, for the contributions are uniformly of a high standard, and the book reflects credit on all associated with it Its encyclopædic range and its great quantity of recorded facts make it an essential reference book to every worker in the subject The editorial work has been so well done that the great quantity of material is everywhere clear and orderly Two indexes are provided, and it is well printed and bound The discussions given are apparently second thoughts, for they are terse and meaningful, much better than the obscure muddle of the truly verbatim record

Comment on such a wealth of topics is difficult, but I noticed one fact that seems remarkable The better understanding of higher mental functions, and their mechanistic basis, that has come in the past decade through cybernetics has shown the outstanding importance of 'memory', both short- and long-term, in every aspect of the higher cerebral functions Yet our knowledge of the physical basis of memory in the brain is to-day almost nothing Our knowledge of brain function is grossly out of balance of what happens from one milli-second to the next a great deal is known, but how a present event in the brain will influence its action in an hour's time, or in a day, or a year, is almost totally unknown Yet it is the action that persists over a day or a year that is the really significant one for our everyday life This lack of balance in our present-day science is shown in the book, for of the 152 contributors, only one specifically considers the effects of a drug on memory But the same paper also shows that research in this direction is by no means forbiddingly difficult

W Ross Ashby

Life in the Sea

Text by Prof Gosta Jagersten Photography by Lennart Nilsson Pp 184 (London G T Foulis and Co, Ltd, 1961) 50*s*

THIS is a book of photographs, a few in colour but mainly black-and-white, of marine invertebrates and a few fishes, taken by Lennart Nilsson The text, and doubtless much scientific guidance, is supplied by Prof Gosta Jagersten, of the Zoological Institute, Uppsala, and director of the University of Uppsala Biological Station, Klubban, Fiskebackskil, on the Gullmar Fjord, where most of the photographs, apart from a few at Trondhjem, were taken

It is much the best book of its kind I have seen Apart from the high technical skill, especially of many of the photomicrographs, notably of protozoa, diatoms and a wide assortment of planktonic organisms, there is a remarkable quality of 'aliveness' about almost all the photographs, scarcely one is a set piece Technical skill and artistic selection are blended with results which will come as a revelation of beauty as well as of biological information to professional zoologists no less than to amateurs and to school children Perhaps the most striking pictures are those showing young pipe fishes emerging from the egg pouch of the male parent, the series (some in colour) showing conflict between an octopus (*Eledone*) and a lobster and another between two bristle worms, reared up with bared jaws Of greatest scientific interest are the pictures of *Protodrilus* with Prof Jagersten's description of the habitat of wave-washed sand and the effect of this on metamorphosis of the larvæ Altogether a book for everyone and fully worth its price

C M Yonge

Water Gardening

By Frances Perry Third, revised edition Pp xviii+338+105 illustrations (London Country Life, Ltd, 1961) 30*s* net

THE content of this book ranges far beyond the scope of the title, and the bulk of it consists of lists, somewhat arbitrarily defined, of plants which all supposedly have some relation to an aquatic environment But the author's net has been cast much too widely, and the rather bewildering catalogue of species and forms could have been with advantage reduced to a judicious selection of plants which are readily obtainable, known to be of some horticultural merit and likely to be amenable to cultivation Instead, it seems that the literature, not always the most up-to-date or authoritative, has been combed and many of the plants listed have little, apart from botanical interest, to commend them in the aquatic garden or its surroundings The reader will find much of interest and profit in those chapters dealing with design, construction and planting of water gardens.

G Taylor

SCIENCE AND GOVERNMENT IN A FREE SOCIETY*

By The Right Hon VISCOUNT HAILSHAM, P.C
Lord President of the Council and Minister for Science

IT is now a commonplace to say that in some respects a nation is highly regarded in proportion as its science and technology command respect I do not, I think, have to prove this proposition But I would wish to begin by qualifying it

It is easy, of course, to demonstrate that the wealth of nations in peace, and their force and power of resistance in war, have largely been a function of their industrial and scientific strength This is why all nations, slave and free, developed and undeveloped, do their best to achieve a high level of scientific and technological investment within their own borders With most statesmen it is a simple question of the survival of their national societies, and the growth of their national wealth, that they should do so

These considerations are obvious, what is not so obvious, and may, therefore, be in more need of argument, is that, at least in its higher reaches, science is not intrinsically a matter that should—or indeed can for long—be pursued solely for the sake of the wealth or the power that its pursuit may bring

All genuine science has its origin in the questioning nature of the free human spirit, in its creative genius, in its power of insight It is not something which can be dictated to either by theologians or ideologues—or, in the long run, by rulers It may be that they can destroy it by repression, or even starve it for lack of material facilities But they cannot by their own act make it live It is doubtful how long they can even cause it to grow by supplying the means of growth It is certain that they cannot, simply by supplying the means, dictate the nature or scope of the discoveries that can be made Far less, indeed, because it is in the nature of scientific research to discover something which is intrinsically new If anyone were able to predict, or pre-empt, the answers to scientific problems, they would not be genuine scientific problems, for the essence of the matter would already be known in advance The discoveries of a Newton, an Einstein, a Darwin, a Planck, or a Rutherford are genuinely not known in advance, and, when they are made, their practical applications are not immediately perceived even by the inventors This is something which lies deep at the root of the subject, and which statesmen and their people would do well to ponder more deeply than they do at present

I say all this without for one instant losing sight of the spectacular achievements of science under the patronage of government, and without doubting for an instant that these achievements will be multiplied in our time—nor that a great deal of my own time as Minister must be spent precisely in seeking to multiply them in my own country Nevertheless there is a sense in which I continue to regard these wonderful achievements as something of a paradox and I am tempted to speculate whether, in the end the influence of a so obviously materially motivated interest by government in science will not obscure the very insights on which creative science is essentially based In the U S S R , and even perhaps in the United States, to look no nearer home, I see some signs that this may ultimately be so, if it does not prove to be the case it will be because the creative human genius in science as in the arts, may prove too strong for the material motivation of the Governments which seek to direct its course

However this may be, I begin by insisting that pure science is intrinsically as much a branch of culture as history, philosophy or poetry, and that the relationship between Government and pure science is essentially the same as that between an enlightened Government and the artist—that is, the relationship of an enlightened patron and not that of an employer My point is that at its most vital and critical growing point, that of fundamental discovery, the Rutherfords and the Darwins have to be treated with not less respect than the Shakespeares and the Miltons and the Goethes Historically, science is born of two highly respectable parents, the belief in the uniformity of Nature which was the natural child of monotheism in religion, and the freedom of expression and thought which was the product of the Renaissance I would claim that if Government sought to interfere with the scientist in the absolute freedom of his explorations, and the integrity and independence of his speculation, it would ultimately destroy its real source of vigour, or alternatively frustrate its purpose by undermining the scientist's confidence and his will to co-operate

But to this thesis there is a clear antithesis The constant temptation on the part of Government to do this thing is matched by a constant need on the part of the scientist, especially in some ways the purest of the pure, to seek Government help on an ever-increasing scale In most fields the day of the gifted amateur in science is rapidly closing Some of the research tools of the modern scientist are very expensive The education of the modern scientist is not only protracted and complicated, but almost as expensive as the tools he employs He is increasingly dependent on the patronage, in some form of Government

But in exercising its patronage the Government is not, and cannot be disinterested The immense advantages which enure to a State that makes use of the discoveries of science—and trains its citizens to make them—are such that all States make some sort of an attempt to do so, and compete eagerly with one another in the attempt Who will deny that, in the process, both the State and science have to some extent been corrupted ? Three-quarters of British Government money spent on science come directly from the defence budget The proportions in the United States and the U S S R are probably greater, indeed, it is questionable whether the basic organization of scientific endeavour in the U S S R makes any serious attempt to give civil science as such an independent life and existence at all In Britain the creation of a Minister for Science whose terms of reference excluded defence was something of an act of faith, and has come in for some criticism. It is probably fair to admit that a price had to be paid for this. Nevertheless, I am still of the opinion that, in the long run, the marriage between science and defence is corrupting, and will at best turn science from a liberating to a destructive force, and at worst ultimately dry up the wells of inventiveness in the scientist himself. There is a point, indeed, at which technology itself will perhaps corrupt and destroy the scientific inventiveness on which it was based.

---

* Substance of an address to the Arbeitsgemeinschaft fur Forschung des Landes Nordrhein-Westfalen, Dusseldorf, on September 27

I therefore earnestly hope that at least a proportion of scientists in all countries will retain their freedom and integrity. It may be that the mere necessity to train all scientists in the genuine techniques of free speculation and invention will cause them to break their shackles. Certainly I am glad myself that my own position of Minister for Science is organized in such a way that neither defence nor even the short-term requirements of technology have been allowed to claim complete mastery over scientific endeavour.

But I would think that the strongest guarantee of a correct balance lies in a healthy relationship between Government and universities—not simply as regards the faculties of natural science, but generally in relation to their whole cultural purpose. There may be many means of making adequate government support available without infringing academic freedom. We are naturally proud in Britain of our own system, which allows government funds to be administered, in effect, by the universities themselves. I am not myself saying that this is the only possible way of achieving the desired object. But it remains, I think, at the basis of any healthy relationship of Government and science.

Indeed, whatever the temptation to militarize or commercialize science, there is a practical consideration which tends in the other direction. No country in the world has ever successfully set up a Department of Science, in the sense of a Ministry directly controlling the pace, the scope and the methods of scientific research. This is due to two considerations. The first is that the strategic planning of science cannot be undertaken without full participation of the scientists themselves—and by these I mean, not just a staff of administrators with scientific degrees, but also men and women who actually carry on scientific work, whether in universities, government research stations, or industry. This is as true of the socialist U.S.S.R. as it is of the capitalist United States, and it is not less true of Britain. Until a short while ago, Russian science was run by the Academy, and though the recent change by which it is now subordinated to a co-ordinating committee is almost certainly a move towards tighter control by the State, it is not a means of taking scientific decisions out of the hands of scientists, or reducing science to a mere branch of government administration.

There is also a theoretical argument which tends in the same direction. There is a sense in which there is no such thing as science, but only sciences. Another way of stating this is to say that science is in fact an all-embracing term, and that scientific researches into particular fields are functions of those fields and not of a comprehensive entity called science. From one point of view, medical research bears a much closer relation to the climate, population, health, diseases and economic activities of a nation than to their nuclear physics. In terms of science, as distinct from economic policy, it would be meaningless for a Finance Ministry official to try to block a grant for medical research on the ground that the money was needed for a synchrotron. It is true that both projects must take their stand in the queue for the general investment programme. But they are related to other items in the programme more closely than to one another.

What is wanted, therefore, is not a single scientific general staff forming part of a single department of science, but a series of scientific general staffs or Research Councils directing scientific research in the general fields to be occupied, independent of day-to-day bread-and-butter work in those fields, but in close contact with them. At the same time there must be, of course, some body to perform the more generalized function of supervision, looking for gaps or signs of imbalance, and fitting the parts into the general economic, cultural and social pattern of the entire community. This is the pattern of British organization. So, taking medical research again as an example, we have a Medical Research Council, independent alike of the Department of Scientific and Industrial Research and of the Ministry of Health but under a Minister for Science, and of equivalent status to other Research Councils serving other scientific fields, commanding the respect and enjoying the co-operation of the scientists, but serving the public interest through its subordination to a Minister responsible for science, who, in turn, is advised by a general council on scientific policy.

The question arises, however, whether such an organization does not give rise to an ivory tower mentality on one hand, and lack of scientific-mindedness on the other. Critics have undoubtedly claimed that this is so, and it is sometimes said that on one hand British industry is too little conscious of the need for technological progress, and on the other hand, that the Research Councils are too strongly academic and too pre-occupied with fundamental research. I agree that the organization which I have been attempting to outline is not in any way a substitute for adequate technical or qualified staff at the executive and administrative level in industry or Government, indeed, I would go further, and say that it will only work at full efficiency on the assumption that such staff are available and active at every level, and in close contact with the Research Councils. This however, does not diminish the case for the Research Councils, which is based on the need for detachment and independent supervision, and not on the supposition that they are substitutes for an appreciation of scientific and technical factors in those who are responsible for management in Government or industry.

This leads me to another generalization about the nature of my subject. Science is, or at least it should be, all-pervasive, and will not achieve its best results until this is the case. You can never make industry research-minded, whether privately or publicly owned, simply by providing research in government institutions or universities, and, if British experience is any guide, you will not even achieve it only by encouraging co-operative research by associations of individual firms—valuable though such associations be. There is no substitute, at any level, for science 'on the ground'—that is, within the individual industrial or commercial firm, within the individual teaching institution, within the individual government departments and nationalized corporations, and even within the home circle. This may seem impossibly ambitious But I consider it to be an obvious truth, whether you regard science as primarily a branch of culture or as something intrinsically practical in application If the institution of a Ministry of, or for, Science were to obscure the essential truth that science and the scientific approach must be all-pervasive at every level, and cannot be imposed from outside, it would be nothing less than a national disaster

Thus the duty of organizing science in a free society, like all other important duties, begins with the individual and covers the entire society Government is a financing, co-ordinating, participating, training, function Over a large field it is not, and cannot be, directory and executive There are functions in which the main part ought to be played by industrialists, educationists, teachers and scientists themselves.

I now wish to discuss the conditions in which this duty can be carried out, and I begin, as anyone must begin, with the child The clue to the correct organization of science is an adequate pattern of education I would go so far as to say that if we could get this right, we should, in the long run, get everything right If we get it wrong, we shall get nothing right, even in the short run

By far the most important desideratum is the creation of a good general school education You cannot make scientists of the first class out of an uneducated populace. The qualities which go to make a first-class scientist show themselves comparatively late in a child's career In most disciplines a sound knowledge of mathematics is a condition of entry into the profession, in most of the others, such as medicine, a wide general culture is almost indispensable Moreover, from every wider point of view, any attempt—perhaps in order to obtain rapid results, perhaps for short-sighted financial reasons, or possibly even for less-creditable reasons of political or ideological obscurantism—to generate a race of scientists interested only in their own specialities, to the exclusion of general culture or even of other scientific disciplines, would, I hope, be bound to fail. If it were not to fail, and if it were taken to anywhere near its logical conclusion, it would certainly be the most disastrous enterprise on which a developed human society could possibly embark Such a race, narrow, blinkered, unbalanced, humourless, frustrated and—over a large range of human experience—inarticulate, would be one of the most evil that the human imagination could devise, probably a race of slaves designed to serve a race of still more uncultured masters, and, if not slaves, illiterate but technologically proficient tyrants to destroy or enslave the society which brought them into being

To this first proposition, however, I would add an immediate footnote In this sound general education of which I have spoken, science should form an integral part from the first From the time that a child can read, and count up to ten, an element of scientific knowledge and thought should be injected into the curriculum of what he learns, even if it is only the most generalized statements about the universe, the microcosm of the atom, the organization of life and evolution, and the nature of chemical compounds The reason why science is regarded by so many otherwise cultured people as a hidden mystery is because so little of it is injected into general reading and conversation before the age of ten [see also p 387 of this issue] We should not learn our culture —our history, our religion, our ethics, our physics, our mathematics—in a group of watertight vertically divided compartments, or in a series of horizontally divided instalments, but in a wide, integrated, smoothly flowing stream

But behind the general educational pattern lies the need for a sound specialist and vocational training available from the age of fifteen onwards for those who need to know the essential manual skills or crafts, and from sixteen or seventeen onwards for those who seek technician status, or the higher technological or scientific degrees I am not qualified to lay down a detailed or technical prescription for this But I would say generally that there should be more than one road to the top, and that a society which does not make further education, of at least three years, universally available for those who possess the entrance qualification for it, on the basis that it will be availed of by at least 25 per cent of the appropriate age-groups in the population, is seriously under-estimating its requirement. If you put the figure at 40 per cent I would not seriously quarrel, but would say that this remains to be proved

At the spearhead of the scientific movement is the army of research workers, the true frontiersmen of scientific advance, few in numbers, highly specialized in qualification, but on whose efforts depend the success or failure of all How will these work ? Who will direct their work ? How will it be financed and organized ? What is to be their relationship to Government ? These questions are really at the heart of the whole matter, everything else is, in comparison, only on the fringe

In the early days of science, these questions presented no difficulty Science was independent of Government and even, to a large extent, of the formal courses of the university But this is no longer the case The men of whom I now speak take about thirty years to train—five in the nursery, ten in the school, three or four in the university as undergraduates, four or more learning research methods, and perhaps another five working under some kind of supervision Their research apparatus—originally made of glass and brass in an attic or a garage or outhouse—may now cost millions of pounds, like the proton synchrontron at CERN, or the fast breeder reactor at Dounreay, and the supporting structure of constructional engineering, electronics, computers, served by technicians and craftsmen, employs whole industries and forms the basis of life in whole townships and communities Of those who start off on this road, many fall by the wayside On the genius of a small proportion out of the very few who survive the race depends the success or failure of all

Here my first proposition is that, at the highest level, it is ruinous to separate research and teaching It follows that the most advanced scientific work should be located in or near the universities, where this is possible, or directed by university personnel The contrary course—the creation of separate government-sponsored institutes—is attractive and is sometimes rewarded with spectacular results Moreover, considerations of national security may sometimes dictate it But in the end it can be a primrose path, as everyone from the U S.S R westwards who has tried it knows You may gather together all the most promising intellects in a subject, build them a town, equip them with all the most lavish facilities, and the thing will go off like a rocket—at first But after five years—after ten, after fifteen—what then ?

Unless active steps are taken to redress it, there is a danger that intellects will be staler, new blood will not be forthcoming, the stimulus of youth will be absent From a proportion of those engaged, the research potential may have disappeared, even the scientific questions will have changed Instead of a research institute you would then have a monastery which had lost its faith—isolated stereotyped, remorselessly carrying on activities with a diminishing margin of useful results

There have been, of course, remarkable examples of research institutes where the dangers I have mentioned have been avoided, it would seem, indefinitely In Great Britain I would cite the National Institute of Medical Research and the National Physical Laboratory, and in Germany the Institutes of the Max Planck Society But if the dangers have been avoided, it is precisely because they have been recognized as dangers As a general proposition I adhere to the view that there must be the constant stimulus of teaching, or research will tend to die There must be the constant interpenetration of the mature intellect with the adolescent, or it may petrify. There must be a constant outlet for research workers who are ready to pass into teaching or administration, or research may even degenerate into a racket Therefore, where possible, locate your best research in university or teaching institutions If you cannot, you must do the next best thing and arrange for constant interchange of personnel, and regular exchange of ideas between them.

This does not mean that there is no place for government research institutions, or institutions of research collectively organized by or for the benefit of private industry On the contrary, as will be seen, my thesis is that there is room for more and more of these My point is only this: that however much these bodies proliferate, they should where possible locate their best research in or near universities, and that where they cannot do so they should promote the closest possible links with teaching institutions of all sorts

To begin, therefore, with the Government Most governments—directly or indirectly—build the roads, manage the telephones, dispose of the sewage, construct and maintain the harbours, many manage the railways, generate the electricity and gas All are concerned with standards of measurement, heat, light, health and air pollution Most are concerned with the nutrition and health of their citizens, and few can divorce themselves from the efficiency of agriculture All these activities throw up problems of research and development, many of which cannot conveniently be carried on in conjunction with teaching Some activities are intrinsically public in character. Others can efficiently be financed only by heavy drafts of public money It will be a long time before agricultural research is paid for entirely by farmers. Nor can the pharmaceutical industry, the medical profession, or private generosity, finance medical research on an adequate scale Even in the sphere of industrial research there are many general questions, like those connected with fatigue and creep in metals, which lend themselves to government research financed by Government, because they are not so closely connected with any particular private industry as to attract sufficient private finance

Here I would describe in greater detail a British institution which we owe in part to the genius and foresight of the first Lord Haldane, and which has on the whole won the confidence of the scientific world and created the means of providing government finance without sacrificing either academic independence or scientific integrity This is the institution of the Research Councils, of which there are at present four in Britain, the Department of Scientific and Industrial Research, the Medical Research Council, the Agricultural Research Council, and the Nature Conservancy.

The thinking behind the creation of these Councils is to separate the activity of research from the executive business of government and economic activity—keeping medical research separate from the Ministry of Health, for example—and to concentrate it under a number of Councils, composed mainly of working scientists and industrialists with real executive responsibility for the research programmes under their control, with separate budgets negotiated with the Finance Department, and invested with the responsibility, within their several spheres, for financing the training of research workers no less than carrying forward the business of research All operate stations or institutes of their own All finance research in the universities, and one, the Department of Scientific and Industrial Research, co-operates with particular industries in financing joint programmes of research carried out by organizations known as Research Associations, managed primarily by the industries concerned on a co-operative basis, but attracting also government grants through the Research Council

It would, of course, be a logical and attractive arrangement if one could go on to report that the fundamental or basic research in Britain were now carried out in teaching institutions, and that the applied research was all done in government or industrially based research institutions.

Experience, however, shows that, although this may in theory and in practice approximate to the ideal arrangement, no absolute division of function on these lines is either desirable or possible Apart from the obvious fact that any line drawn between basic and applied research is necessarily arbitrary and imprecise, experience shows that the human problems involved cannot be solved satisfactorily on these lines. However closely applied or related to concrete industrial difficulties the work of a research institution may be in intention, in practice it will not retain the services of high-grade scientific personnel if they are to be completely debarred from undertaking fundamental research

At the other end of the scale, no matter how academic may be the work in a university, it is impossible to exclude applied or practical applications or development Contact with the intellectual frontier is a requisite for the mental health and happiness of one, contact with real life an unavoidable necessity for the other Thus no division is absolute, and nothing will substitute for the management of these highly sensitive, highly qualified human beings by suitably qualified and sympathetic scientific bodies assembled for the purpose A close association between basic and applied science, and a constant interchange of personal contacts between industrial and governmental research, and between both and the teaching institutions, are probably a better prescription than a more perfectly formalized pattern of organization

How far is it possible for national Governments and administrations to guide and fertilize science without warping its character and distorting its scope ? I have already pointed out that the gifted amateur, and even the rich private or industrial patron, whether individual or corporate, cannot possibly cover the sweep of modern science and technology, or even the training of the modern scientist , the needs have reached the national scale

But the nation State also has its limitations, even financially, and more still in its terms of reference It is surely no coincidence that, in one field after another, science not just on a national but also on an international scale is beginning to become an actuality. The International Geophysical Year is only one example—in which even East and West co-operated Europe has recently begun to plan to enter co-operatively into space research Britain and the United States are co-operating in the launching of the first British satellite experiments Western European countries co-operate, under the auspices of the European Nuclear Energy Agency, in the *Dragon* High Temperature Reactor project at Winfrith Heath, and in the Halden project in Norway I have already spoken of the internationally owned proton synchrotron at CERN There are projects on foot for both European and Atlantic universities Much of the aid to under-developed countries will be both co-operative and technical What is the future and what are the prospects for enterprises of this kind ?

I would say that a very considerable scope exists for international scientific effort In the long run, I am quite certain that the really ambitious space research, if it is to continue indefinitely, will have to be financed in this way I cannot myself conceive that either medical or agricultural problems would fail to gain by international treatment Many of the longer-term projects in engineering, for example, in the realm of thermonuclear fusion or the direct generation of electrical energy from heat, may well come into the same category.

At the same time I would emphasize that international co-operation is no substitute for national excellence Our experience has been that co-operation is only possible between nations which each have something comparable to offer to one another It is neither practicable nor desirable to create international scientific organizations to make up for a basic want of scientific organization or effort in the individual member countries The new organizations, when they come into being, will be additions to and not substitutions for what is attempted nationally They will be no excuse for the individual member States to neglect either national education or research on a national scale—although duplication of effort can be avoided, and a scale effect obtained by jointly undertaking projects which are in excess of the capital resources available to any one

Hitherto it has been possible for the nation State to stimulate the growth of scientific effort in a variety of different ways—by supporting scientists in the universities or research institutions, and financing their machines and apparatus, and by developing machines capable of practical application in various directions where the State itself is the ultimate user of the machine

But this has meant, in societies both free and servile, predominantly the development of engines of war, even where these have ensuing or concurrent civilian application Where would the aeroplane, the radio, radar, jet propulsion, or, more recently, space research have been but for the constant urge of governments to prevail in two world wars—or should I say in three ? It is useless for governments to protest that their Gagarins and their Sheppards—or their Titovs—have also achieved technical success in realms of peaceful science and technology. Only those nations which have had reason to develop military rockets have actually reached for the stars, and a principal effect of their space flights has been to emphasize the prestige of their military technologies

Is there no means nowadays of governments developing or helping to develop new devices which are just as revolutionary but without the stimulus of war or the fear of it ? The steam engine in its origin, and the internal combustion engine in its inception, were primarily civilian devices What must we do now to stimulate development in a purely civilian sense ?

I must begin by emphasizing that, as between research and development, it is development which costs the money Of the two hundred and fifty million pounds spent on research and development by government departments in Britain, about fifty million goes on research and the rest, I estimate, on development, and of this, of course, a proportion that I would not care to guess at is spent on projects which never ultimately reach fruition

Secondly, I point out that the role of the would-be financier of development is radically different according to whether the financier is, or is not, the ultimate user of the hardware to be produced One reason why so much successful development has been inspired by defence has not been the over-riding importance of the conception of war in the mentality of modern government, it has been the simple circumstance that the defence forces as the ultimate users of the hardware have been able to formulate their staff requirements, undertake their feasibility studies, and finally proceed to development contracts with the makers, without the discipline of the necessity to make a commercial project, but with all the enthusiasm of a potential user whose life may depend on the excellence of the product

It is not easy, in a free society, to reproduce all these conditions in civilian life—even where, as is by no means usually the case, the Government is the ultimate consumer In civil aircraft, in railway engineering, in road construction, radio engineering, electricity generation, perhaps in machine tools and computers, and above all in the peaceful uses of atomic energy, some of the conditions exist, and only in the latter case have the possibilities been at all adequately grasped—with results which have as yet not been fully seen Admittedly there are formidable difficulties—the formulation of the requirement, the provision of government finance for a project which may ultimately enure at least in part to private profit, the placing of a contract selectively (which could give ground for scandal and abuse); but we shall not advance farther until we get our feet wet It may be that here, too, there is scope for the pooling of resources internationally

Of one thing I am quite certain The preservation of a technological lead cannot long be maintained by means of commercial secrecy Commercial, like military, security always breaks down in the end, and what advantage exists in priority is obtained by industrial experience in production rather than by the maintenance of technical secrets

A nation remains in the forefront technically, not by patenting its devices but by keeping ahead in invention and development, and this is a complex achievement which lies only in part within the province or power of government to promote Let us remember that science is an achievement of the human spirit, and resolve that the European peoples will foster it for its own sake rather than for the wealth and power that it will bring The respect for truth, the freedom of intellect, the moral discipline that it engenders, are worth more than these Get them for their own sake, and my conviction is that what remains will be added unto us

SYSTEMATIC MEASUREMENT OF FALL-OUT IN CZECHOSLOVAKIA UP TO 1961

By Prof W. SANTHOLZER, G MACKU and J. PODZIMEK

Institute of Medical Physics, Charles University Medical Faculty,
Hradec Králové, Czechoslovakia

SYSTEMATIC measurements of fall-out in Norway[1] showed that monthly average concentration of fall-out materials in precipitation after high-yield test explosions reaches a peak value in about six months, and then decreases with a half-life of about one month Our systematic measurements of fall-out in precipitation in Hradec Králové, Czechoslovakia, during the past four to five years provided evidence that the activity of radioactive fission products from fall-out during November 1956–December 1959 showed a trend similar to that in Norway[2] (Fig 1) The peak of the activity in April 1959 has about the same value, 3,960 $\mu\mu$c /l precipitation The minimal value during November–December 1959 was about 20 $\mu\mu$c /l

Detection of French Nuclear Tests of 1960

In Fig 1 are shown the results of our measurements also during January 1960–March 1961 The increase in activity of rain-water in March 1960 after the first French nuclear test in the Sahara Desert on February 13, 1960, was very pronounced but transitory Activity of fission products reached its highest level in the collection of rain-water of March 1, namely, 25 9 mμc /l In the collections of March 4–12 the activity was about 5 mμc /l The concentration of radioactive fission products from fall-out in the air at ground-level in Hradec Králové during March 1960, studied by measurements made on dust collected by a membrane filter assembly, showed no pronounced increase in activity (The concentration was about 1 $\mu\mu$c / m^3) It is interesting to note the measurements of Patterson and Lockhart on the eightieth meridian network of air-filter stations[3] The activity of fission products reached its highest level at Miraflores, Panama, in the collection of February 26–29, and this station received the first indication of fission products in the 2-day collection of February 24–26 It is therefore probable that the radioactive cloud from the first French nuclear test reached our station in Hradec Králové at the beginning of its second revolution around the globe, its velocity of propagation being about 100 km /hr The attempt to explain the relatively high level of the activity of rain-water and the simultaneously low level of the activity of surface air sampled on March 1 in Hradec Králové is made in the last paragraph A sharp increase in the level of activity occurring some time during February 28–March 1, 1960, in Surrey, England, and evidence which suggests that this was due to the first nuclear weapon test in the Sahara, was described by W Anderson *et al* [4]

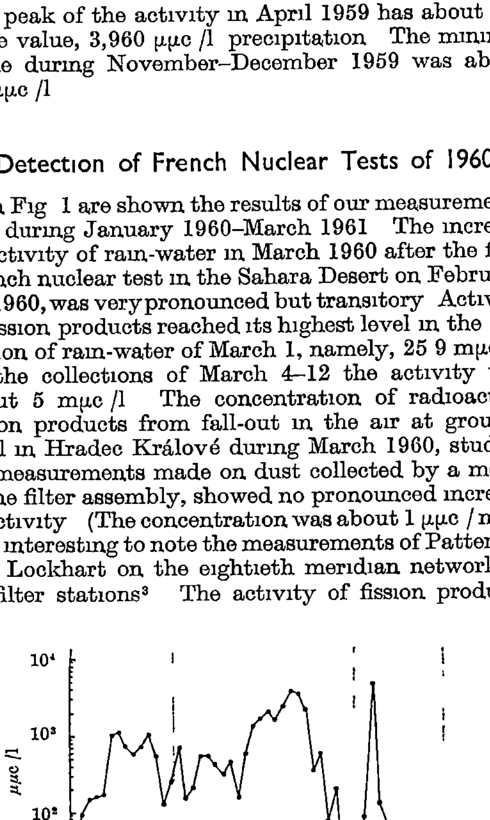

Fig 1 Monthly average concentrations of materials from fall-out in precipitation

Fig 2 shows the decay of three representative samples plotted on a log activity versus log time-scale with February 13 as the origin Fig 2 is similar to the figure published by Y Feige *et al* of the Israel Fall-out Monitoring Service[5], where the main impact of the first French nuclear explosion was already on February 17 Our Fig 2 demonstrates that the exponent n in the formula of the decay $A = kt^{-n}$ is 1 2–1 4 The long-lived background becomes evident after the elapse of 120–160 days, according to the level of the activity of fresh samples We followed the decay during 400 days

After the second French nuclear test, on April 1, 1960, we picked up radioactive materials in rain-water on April 9 The initial activity was relatively low, about 0 4 mμc /l, and average long-lived background activity had to be subtracted after 30 days

Patterson and Lockhart[3] relate the second rise of the activity during early April to the February test, since debris from the French test of April 1 would not be expected to arrive so soon, and debris from the much smaller second test could be hidden by residual activity from the first test If we relate at our sampling station the second rise during early April to the first French test, the exponent n in the formula $A = kt^{-n}$ would be 3–4, which is unlikely The first 'half-life' of our sample collected on April 9 was 9–10 days, which is probably due to the fresh activity

In Rumania, Mageru *et al* observed the transitory increase in activity during February 23–25 and March 16–20, 1960, in the air-streaming from the Mediterranean[6]

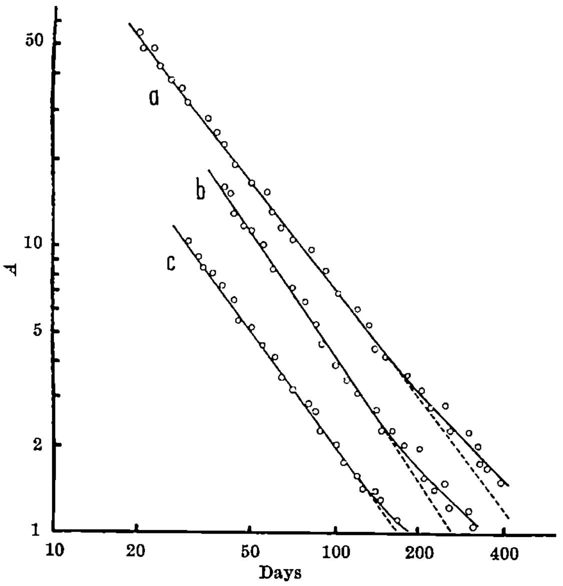

Fig 2 The decay of three representative samples in the collection of March 1–8, 1960, after the first French nuclear test on February 13, 1960

Autoradiograms of radioactive dust particles from the second French test were obtained by V Havlovic in Pilsen, Czechoslovakia[7]

After the third French test on December 27, 1960, we did not observe any marked increase in activity

Collection of Fall-out and Typical Decay Curves

In addition to the collection of rain-water samples, the fall-out was collected every second or third day by the pot method, which is efficient[8]. The collecting dishes, made of polyvinylchloride, have high borders and a collecting area of 1 m ² A thin layer of distilled water is maintained on the bottom. For control purposes the fall-out is also collected once a month After annealing at a temperature of about 600° C., the sample is again moistened and uniformly applied to an aluminium dish, 3 cm ² in area After drying, and three days after collection, the activity is measured with a Geiger-counter for beta-rays The number of pulses is recorded with automatic equipment of our own construction on a paper tape[2] The samples are also changed automatically. Strontium-90 + yttrium-90, obtained from the Dosimetric Department of the Institute of Nuclear Research in Prague, was used as a standard

Fig 3 shows the activity of fall-out in the period when nuclear tests ceased during November 1, 1958–February 29, 1960, and also during March 1, 1960–March 31, 1961 Activities are in mc /km ²/ month, and plotted as logarithm of activity versus time. In Fig 3 are used activities collected monthly, that is, at the end of each month With this value we compared the total of daily activities for the month considering the radioactive decay The maximum in March 1960 is not so pronounced as in Fig 1, because the fresh activity in March 1960 decayed more quickly than relatively older activities at the beginning of 1959 In the first quarter of 1961 the monthly average activity of fall-out was 0 4 mc./km ².

Fig 4 shows the decrease with time of activity of rain-water collected on May 4, 1959 (sample *a*), and on March 1, 1961 (sample *b*) Approximate date of nuclear test was determined graphically. The values of :

$$1 \cdot {}^{1\,2}\sqrt{A} \text{ and } 1 \,.\, {}^{1\,6}\sqrt{A}$$

are plotted on the ordinate axis, thus producing curves a', a'' and b'. (The curve b'' is not plotted) In the period of the first 150 days they are straight lines, which intersect the time-axis in July, and October 1958 and in February 1960 For the first French test one may plot the values of $1 \; {}^{1.2}\sqrt{A}$ to obtain the right date of the test For the sample collected on May 4, 1959, which was one of our last relatively strong active rain-water samples in the spring of 1959, it is impossible to determine by using the rather insensitive graphical method which date of the nuclear test is correct[9] But a control graphical determination makes some date in October 1958 more probable It consists in the fact that for the relation $A = kt^{-n}$ there is a linear dependence between the time difference (τ) of the dates corresponding to the activities, the ratio of which was chosen constant, for example, $A_n \,.\, A_{n+1} = 2$, and the time (T) corresponding to the first activity Relation $A = kt^{-n}$ may be written in the form $A = a\ (T - T_0)^{-n}$, where T is the date of measurement, T_0 the date of the nuclear test, and then transformed in the linear dependence $\tau = c\ (T - T_0)$, where the constant c is dependent on the exponent n, $c = {}^{n}\sqrt{2} - 1$ Thus, $n = 1\ 2$ appears more probable (curve a')

In fresh samples collected during March 1–14 two groups of beta-rays were roughly determined by absorption measurements with aluminium foils 0 7 MeV and 1 5 – 2 1 MeV In agreement with Akpinar[10], it was shown that the energy of beta-rays

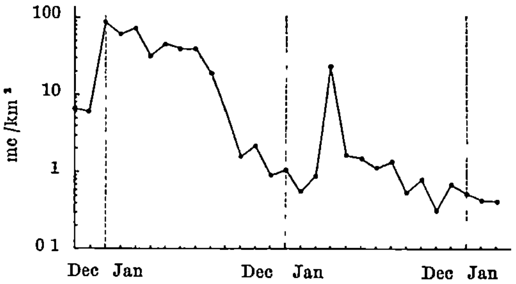

Fig 3 Concentrations of fall-out materials in mc /km ²/month

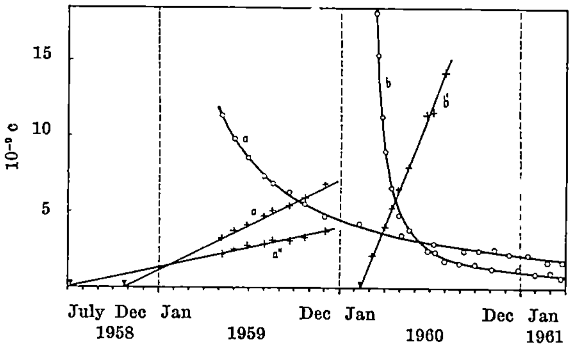

Fig 4 Typical curves of decrease in activity with time of two samples of rain-water collected on May 4, 1959 (*a*), and on March 1, 1960 (*b*) Approximate dates of nuclear tests were determined graphically from the initial part of the curves, where the background is negligible

varies with the age of the sample, but due to relatively large masses of samples we were unable to use this method for rapidly determining the age Old samples collected in spring 1959 and studied by absorption measurements showed the group of beta-rays about 3 MeV

The energy of the gamma-rays of samples in the collection during spring and summer 1959 was roughly determined from absorption measurements with copper and lead plates, with a scintillation counter The result is 0 2 MeV and 0 8 MeV This is in rough agreement with gamma-scintillation spectra of the fall-out[4,11], and with the main gamma-emitting nuclides to be expected in a 6–18 month-old mixture of fission products[12]

The seasonal variation of the first half-life[13] of our samples corresponds roughly to the calendar of nuclear test explosions, as was more exactly determined by D H Peirson *et al* [14] on the basis of the ratio of zirconium-95/cæsium-137, which is a useful index of age or origin of the mixture of fission products

Radiostrontium determinations in the fall-out were made using well-established methods[15] (Separation was carried out by the Chemical Institute of the Medical Faculty of the Charles University in Hradec Králové) The average concentration of strontium-90 found by us in rain-water collected during the first two quarters of 1959 was about 10 μμc /l , in the last quarter about 1 μμc /l , and in the first quarter of 1960 about the same This is in agreement with the measurements of W Anderson *et al* [12], who proved a marked reduction of the average quarterly concentrations of strontium-90 in rain-water collected during 1959

Correlation with Meteorological Data

The reality of the maximum of man-made radioactivity in rain-water measured on the territory of Č S S R at the beginning of March 1960 is confirmed by comparison with the meteorological situation A picture of the upper air flow at the 500-mb level has shown that the contaminated air mass after the first Sahara test reached our country in 17 days During this time the trajectory of the air mass could be traced over northern Egypt, Iran, northern India, Vietnam, southern China, the Pacific, the southern parts of the United States (February 26), the Atlantic Ocean and northern France It is characterized by the very rapid progress, especially in the part above the Atlantic Ocean, where the velocities in the jet-stream surpassed 100 km /hr The trajectory explains the measured maxima of the radioactivity in air samples in Israel on February 17, a sharp increase of the activity in Surrey, England, on February 29 and on March 1 in Germany On an average, however, following the trajectory, we find the maxima of the air activity above the territory of Israel on February 15 or 16 From this we arrive at the hypothesis that a radioactive cloud settled relatively slowly and that the air trajectory in the lower levels was probably not the same as in the 500-mb level

The abnormally high level of artificial radioactivity of atmospheric precipitation on March 1 does not correspond in Hradec Králové to the maximum, which is not expressed so well in the histogram of air activities We explain this fact by the process during which radioactive particles were bound in clouds and washed out below the clouds by the falling precipitation elements In this case a decisive part is played by the evaporation of rain-drops As the intensity of evaporation increases with decreasing dimension of drops, we could expect, at 11 hr on March 1, when the cold front with smaller intensity of precipitation and smaller dimensions of rain-drops passed over our country, a higher radioactivity of rain-water, although the measured values of air activity was relatively low

We are indebted to Prof F Běhounek, member of the Czechoslovak Academy of Sciences, for valuable advice and encouragement during this work.

RADIOACTIVE FALL-OUT AND THE TESTING OF NUCLEAR WEAPONS

STATEMENT BY THE MEDICAL RESEARCH COUNCIL

IN December 1960 the Medical Research Council published its second report "The Hazards to Man of Nuclear and Allied Radiations" (Cmnd 1225), which included an assessment of the levels of exposure to radiation which had resulted from test explosions up to that time The resumption of nuclear weapon testing in the atmosphere by the U S S R has, however, resulted in the further release of radioactive fission products and, at the request of the Government, the Council has issued a statement (October 24) which attempts to put in perspective some of the more important considerations that result from the new situation A review of this subject would not have been possible without help from many people, and the Council would like to record in particular its indebtedness to the Agricultural Research Council and the United Kingdom Atomic Energy Authority, members of the staff of which have provided valuable advice and assistance

Mechanism of deposition of fall-out Work on the deposition of fall-out from weapons detonated during 1958 and in previous years has shown that the rate at which fission products pass from the stratosphere to the lower atmosphere and thence to the Earth's surface varies greatly according to the size of the explosion and the height, latitude and time of year at which it occurs Deposition from large explosions has been found to be most rapid when debris is released into the lower stratosphere in high latitudes during the autumn

Types and sources of radiation exposure from fall-out The significance of tests involving substantial and rapid fall-out is that, soon after the tests, considerable quantities of short-lived radioisotopes, which will not have been retained in the stratosphere sufficiently long to decay to negligible levels of radioactivity, are likely to be deposited on the Earth's surface These short-lived components of fall-out contain both materials, such as zirconium-95, which are not absorbed into the body but contribute to the external radiation received by the whole body, and materials which are absorbed into the body such as iodine-131, which becomes concentrated in the thyroid gland If present in sufficient amounts, these short-lived materials may, in the short time during which they retain their radioactivity, give doses comparable with those delivered over much longer periods by the longer-lived materials produced in the same explosions

The chief longer-lived components of fall-out which require consideration are cæsium-137, carbon-14 and strontium-90 Cæsium-137 and carbon-14 are of importance because they give rise to general irradiation of the body, including the gonads The dose-rate from carbon-14 is very much lower than that from cæsium-137 but, as it will continue for very long periods, the total dose over hundreds of generations may be similar Strontium-90, both because of its long half-life and because it becomes concentrated in bone, causing prolonged irradiation of bone and bone marrow, is still regarded as the most important single indicator of the possible total hazard to the individual

Assessment of the hazard from fall-out prior to the present tests. The Council's second report on "The Hazards to Man of Nuclear and Allied Radiations" (Cmnd 1225), which assessed the possible extent of the hazard caused by test explosions up to the end of 1958, provides some background for considering the possible consequences of recent tests

With regard to the genetic effect from all test explosions which had taken place up to the end of 1958, the Council concluded that the mutations which might be caused were likely to be few in relation to those produced by natural radiation the latter are themselves believed to form one-tenth or less of the mutations newly arising in any generation

As to effects on individuals, among the most important components in fall-out are iodine-131 and strontium-90 From the amounts of iodine-131 observed in human thyroid glands, the Council concluded that the average thyroid dose delivered by this radioisotope as a result of nuclear explosions which had taken place prior to its 1960 report was unlikely to have exceeded one-quarter of the radiation received from natural sources during any year

Investigations of strontium-90 in human diet in the United Kingdom were commenced in 1955 and were considerably expanded in 1958 The contamination of milk receives particular attention because dairy produce contains most of the strontium-90 which the population ingests Samples of milk drawn from depots handling more than 40 per cent of total production are examined Other foods are also sampled, so that the average strontium-90 content of diet throughout Great Britain can be assessed

Between 1958 and 1959, the ratio of strontium-90 to calcium in average diet in the United Kingdom increased by 50 per cent, but the recent Agricultural Research Council report (*ARCRL* 5) shows that in 1960 it decreased to little above the 1958-level This decrease was due to the reduced rate of fall-out consequent on the cessation of testing and reflected the fact that, when the radioactive fall-out was relatively high, the contamination of diet was due primarily to the direct entrapment of the recent deposit on growing vegetation Strontium-90, however, also enters plants from the soil. This is a slower but continuing process so that, even if fall-out ceased, diet would continue to be contaminated, though at a reduced level, for a considerable period

The results of assays of human bone are now available for the five years 1956–60 In each year the highest concentration of strontium-90 was found in children about one year old In this age-group there was a progressive but slow rise each year until 1958, a doubling of the 1958 value during 1959, but a fall in 1960 which has continued in 1961 The average value in these infants of 4 strontium units (that is, 4 $\mu\mu c$ per gm of calcium) at the peak in 1959 was about a sixteenth of the value (67 strontium units) regarded by the Council as the maximum permissible average value in the whole population

Children born in the year 1955 have been exposed to strontium-90 from their diet during their whole life-time Although in 1956 the average value in their bones was 1 strontium unit, the value in 1960 was only fractionally greater (1 4 units) Older children have formed only part of their bone structure from contaminated food, and the bones of those born between 1945 and 1950 showed only 1 strontium unit in 1960

Estimation of additional exposure due to recent atmospheric tests The recent tests by the U S S R are reported to have included explosions both in the kiloton- and the megaton-range and to have occurred in Central Siberia and the Arctic As would have been expected from experience in 1958, the radioactivity reaching the ground in recent weeks as a result of the present series of explosions has come mainly from short-lived components which are deposited within a few weeks of the explosion The deposition of longer-lived components, such as strontium-90 and cæsium-137, is likely to be greatest next spring

Since iodine-131 is the main short-lived isotope absorbed into the body, extensive measurements are being made of levels of iodine-131 contamination following the present series of tests Early results of the survey, which is being carried out by the Agricultural Research Council, are given in the appendix

It is estimated that the average radiation exposure to the thyroid from this isotope in the fall-out already measured in the United Kingdom from the present tests is likely to be less than the figure of one-quarter of the radiation received from natural sources during any year However, the value for infants in their first year of life may now approximate to that received annually from exposure to natural sources

Because iodine-131 is taken into the body predominantly through milk, the Medical Research Council has had under review the maximum sustained level in milk which might be regarded as allowable. It has based its recommendations on similar criteria to those used in setting the dose-levels permissible in the general population from strontium-90 It has concluded that an acceptable dose would not be exceeded in any age-group of the population unless an average concentration of iodine-131 in milk of 130 μμc per litre was exceeded over a period of one year, or higher concentrations for correspondingly shorter times The level has been set to provide a margin of safety for the section of the population in the group in which the dose-rate would be highest, namely, infants up to the age of 1 year, considerably lower radiation doses would be received by older children and adults consuming the same milk Allowance has also been made for the likely variation in the concentration of radioiodine in local milk supplies The dose referred to will not be reached unless present levels of iodine-131 continue for several months as a result of further weapon tests or are substantially increased A marked decrease may be expected within a few weeks of the cessation of tests

As the highest fall-out rate of some of the longer-lived radioactive substances, such as strontium-90, may be expected in the late spring of 1962, it is not yet possible to predict the total additional radiation dose to which the population has been committed by the recent tests However, as the levels of radioactivity measured in air have been similar to those observed at an equivalent time after explosions in the autumn of 1958, there is at present no reason for believing that tests from which fall-out has so far been detected will involve an additional radiation exposure from external radiation or from strontium-90 which differs greatly from what has been experienced hitherto It may be concluded that strontium-90 from tests so far carried out will not give rise to levels in bone approaching those which the Council laid down in its report of December 1960 as the maximum permissible in the general population

Consideration has also been given to the inhalation of radioactive materials, including plutonium It has been concluded that the extent of radiation exposure from such sources is unlikely to be comparable in importance with that from the other sources mentioned

The Council is informed that it is not expected that underground tests, such as the United States has been carrying out, will contribute to world-wide contamination

Possible consequences of the explosion of a fifty-megaton bomb It appears likely that the explosion of a fifty-megaton bomb during the present series of tests would cause the total energy released from this series to correspond approximately with that of explosions occurring in the two years 1957–58 (according to the Ministry of Defence statement of May 5, 1959) If the bomb is exploded in the atmosphere, the resulting fall-out will depend on the extent to which the energy is due to fusion rather than fission, and on the altitude and site of the explosion

The explosion of such a bomb in the atmosphere in northern latitudes during the autumn could be followed by considerable fall-out of shorter-lived radioisotopes Deposition of radioiodine due to the series might then be substantially greater than that from previous tests, and the contamination of milk in the subsequent weeks might cause the annual mean level to approach that already specified, namely, 130 μμc per litre

Radioisotopes of medium half-lives, such as zirconium-95, might be expected to raise the level of external radiation in the open for some months by an amount comparable with the dose-rate received from natural sources

It is not yet possible to predict with any accuracy the total additional dose of radiation to which the population will be committed by the current series of Russian tests, including the explosion of a fifty-megaton bomb Concentrations of strontium-90 in bone in young children might rise in the course of one year to about twice the maximum level observed hitherto, but the level regarded as the maximum permissible one by the Medical Research Council would not be reached

Arrangements for monitoring and assessing the fall-out situation Regular measurements of radioactivity in rain, drinking-water, food (including milk), air, soil, vegetation and human bone, are continuing according to a country-wide programme under the supervision of the Medical Research Council and the Agricultural Research Council The results of measurement of radioactive fall-out are published at frequent intervals Premature attempts to interpret the significance of individual early measurements directly in terms of human hazard can be extremely misleading Variations in the measurements are to be expected, both from day to day and as between one place and another The significant factors are average levels over long periods of time

The situation with regard to fall-out and the hazards from it is kept under close and continuous review, and the bodies responsible for so doing have undertaken immediately to inform the Government if there should be any major change in their assessments

Appendix: Measurements of Iodine-131 in Milk

When it became apparent that the new series of nuclear explosions might lead to appreciable quantities of iodine-131 in milk, the Agricultural Research Council Radiobiological Laboratory commenced an examination of milk from eight depots or farms located in central and southern England, Wales Scotland and Northern Ireland The samples are analysed frequently, usually daily The mean results so far obtained are shown in Table 1

In the first few days of the week commencing October 15, 1961, the average level fell to below 100 but those results which are now available for the

Country-wide mean weighted for production		113

latter part of that week indicate a return to the levels observed ten days previously

More detailed investigations of the general level in milk throughout the country were made for October 1 and 15 On these dates representative samples were obtained from depots which together handle more than 40 per cent of the total milk produced in each of ten zones into which the whole country has been divided The statistical organization of this elaborate scheme, which is also in operation for strontium-90, has been described in reports by the Laboratory The average results for the two sampling occasions are shown in Table 2.

The means shown in the two tables are in close agreement and the significance of the figures is discussed in the foregoing statement

NEWS and VIEWS

Electrical Engineering at Manchester : Prof. C Adamson

Dr Colin Adamson has been appointed to a newly created (second) chair in electrical engineering in the Faculty of Technology in the University of Manchester. Dr Adamson gained a B Sc (Eng) degree at the University of London in 1947, following work at the Hull and Bradford Technical Colleges He qualified for the degree of M Sc (Eng) in 1952 as a result of research work while working as assistant lecturer in the Bradford College and as research engineer at A Reyrolle and Co , Ltd He was appointed lecturer in electrical engineering at Manchester in 1952, and senior lecturer in 1959 He has been awarded the degree of D Sc this year Dr Adamson has been responsible over the past few years for the development in the Manchester College of Science and Technology of an extensive Power Systems Laboratory, for both undergraduate and postgraduate work, the latter forming a large sub-section of the postgraduate school in electrical engineering His various projects have received substantial industrial support, much of it under contract He is a representative on the British Electrical and Allied Industries Research Association, and has served on committees of the Conférence Internationale des Grands Réseaux Electriques He has recently served, by invitation, as visiting professor at the University of Roorkee, India, under the Colombo Plan, and has lectured at the Universities of Washington and Wisconsin

Municipal Engineering at Manchester : Prof J R. D Francis

Mr John Robert Dark Francis has been appointed professor of municipal engineering in the Faculty of Technology in the University of Manchester, in succession to Prof R J Cornish, who recently accepted a similar appointment in the University of Delhi, India He will take up his post in January 1962 Mr Francis, who is forty-one years of age, gained honours in engineering at the University of London in 1940, following work in the Brighton Technical College After service as lieutenant in the Royal Naval Volunteer Reserve he was appointed to a lectureship in the Department of Civil Engineering at the Imperial College of Science and Technology in 1946 He was appointed reader in fluid mechanics at that College in 1958 Mr Francis has been engaged in research in fluid mechanics and has been concerned in the hydraulic design and model testing of several civil engineering works, including the Owen Falls Dam (Uganda), Tema Harbour (Ghana) and the Baldershead Dam (Durham) He held a fellowship at Woods Hole Oceanographic Research Institution, Massachusetts, during 1952–53, and has recently lectured at the Nigerian College of Technology, Zaria, and the Kumasi College, Ghana

U S National Bureau of Standards : Dr Y Beers

Dr Yardley Beers has been appointed chief of the Millimeter-Wave Research Section, Radio Standards Laboratory, Boulder Laboratories–National Bureau of Standards, U S Department of Commerce He joined the staff of the Bureau in June 1960 as a consultant in atomic frequency and time-interval standards. Dr Beers was a member of the staff of the Radiation Laboratory at the Massachusetts Institute of Technology during 1942–45, a consultant to the Brookhaven National Laboratories with the Atomic Energy Commission, 1947–59, and a teacher of physics in New York University for fifteen years, eventually achieving the status of full professor In 1956, Dr Beers worked as a Fulbright scholar with the Commonwealth Scientific and Industrial Research Organization in Sydney, Australia. During his stay, he was also visiting professor at the University of Sydney His special fields of research interest are nuclear physics, microwave spectroscopy, and the electronics connected with these fields

The Charles F. Kettering Laboratory, Yellow Springs, Ohio

Dr Leo P Vernon has been appointed director of research of the Charles F Kettering Laboratory in Yellow Springs, Ohio He is well known for his work on photosynthesis and has recently returned to his former position as professor of chemistry in Brigham Young University after a year's sabbatical leave, which he spent with Prof Hugo Theorell at the Nobel Institute, Stockholm, Sweden Mr Justin C Crawford has been appointed director of laboratory administration in the Laboratory Mr Crawford will be responsible for all non-scientific activities and business administration A native of Chicago, he has served with the Standard Oil Co of Indiana since 1948, where for the past five years he has been manager of engineering administration

Tristan da Cunha

The island of Tristan da Cunha is the subject of a special exhibition at the Geological Museum, South Kensington The geology is described with the aid of maps and diagrams, and characteristic volcanic rocks collected by the Shackleton–Rowett expedition during the voyage of the *Quest* in 1921–22 are also shown A series of photographs illustrates the rugged topography of the Island, which is related to its volcanic origin A display of projected colour transparencies is a special feature of the exhibit Charts of historical interest, lent by the Admiralty, dating back to the 1827 Admiralty Survey by Cooling, are mounted on a separate screen Although Tristan da

Cunha is a volcanic cone with a crater lake at the summit, there has been no previous record of eruption during historical times The island does, however, lie on the flanks of the Mid Atlantic Ridge, which is a belt of crustal weakness extending from Jan Mayen Island, through Iceland and the Azores, southwards towards the Antarctic The nature and extent of this submarine feature were investigated during the recent International Geophysical Year

Award by the Fleming Memorial Fund

THE Trustees of the Fleming Memorial Fund for Medical Research have made their first grant This is to the University of Oxford and amounts to £48,000 for the Sir William Dunn School of Pathology at Oxford, headed by Sir Howard Florey The grant is in connexion with electron-microscopy work at the School, where the purification of penicillin was achieved and its clinical use made possible Recently, too, cephalosporin *C*, a penicillin-like antibiotic active against some important penicillin-resistant bacteria, was discovered at the Sir William Dunn School of Pathology

The Fleming Memorial Fund for Medical Research was launched in March this year in memory of Sir Alexander Fleming, discoverer of penicillin, to assist basic medical research Its British and international appeal, with a target of £1 million, lasts until March 1962 So far more than £370,000 has been raised

New Thinking in School Chemistry

THE Office for Scientific and Technical Personnel of the Organization for European Economic Co-operation arranged a seminar held at Greystones, Co Wicklow, during March 1960, to deal with the status and development of school chemistry teaching (see *Nature*, 186, 208, 1960), and the report has now been issued with the title "New Thinking in School Chemistry" (Pp iii+215 Paris Organization for European Economic Co-operation—Office for Scientific and Technical Personnel, 1961) The contributions and discussions show that there is considerable difference of opinion on some topics Some favour a dogmatic theoretical treatment beginning with the atom and electron as familiar modern concepts and proceeding to the development of theories of structure and bonding, the teaching being largely centred on the periodic table What one speaker calls 'stick-in-the-mud experiments' will not take a prominent place It is felt that distinction of *s* and *p* orbitals might be too difficult There is sharp disagreement among those favouring this approach as to the meaning of the theories, and teachers using this method will obviously need annual refresher courses An American speaker states that in some schools there the teaching begins with organic chemistry Other speakers, including two from the United States, explain schemes in which models to illustrate atomic linking and molecular structure are made by the pupils Some think that this will take too much time and will be costly Opinions are divided on the value of films Another group of speakers favours an experimental approach and thinks that practical work is desirable Qualitative and quantitative analysis can illustrate general chemistry and inculcate habits of neatness and accuracy Some suggestions for new experiments, including the use of paper chromatography in qualitative analysis, are made Summaries of the discussions, three joint reports, and recommendations for future action close the proceedings

Radiation Botany

THE first number of *Radiation Botany*, a new international journal devoted to plant radiobiology and related subjects, was published in September It is edited by A H Sparrow together with an editorial board drawn from seven countries (*Radiation Botany*, Vol 1, No 1, September 1961 Pp 100 Annual subscription rates (*A*) for libraries, government establishments, research laboratories, etc , 140*s* , 20 dollars, (*B*) for individuals who place their order directly with the publisher and certify that the journal is for their personal use, 70*s* , 10 dollars London and New York Pergamon Press, 1961) This first issue of a hundred pages consists of eleven scientific contributions the subject-matter of which includes, factors affecting responses of plants to radiation, root absorption of fission products derived from underground nuclear explosion, morphological responses to gamma-rays and the influence of radiation on chiasma frequency These and other topics dealt with illustrate the main aim of the journal, which is to be concerned with the effects of ionizing radiations on plants It will, however, also be devoted to the more technical aspects of plant irradiation Each contribution is usefully prefaced by abstracts in English, French and German, and papers are acceptable in any of these languages.

The journal is attractively printed in a style in keeping with the modern nature of the subject The choice of type, paper and general layout makes *Radiation Botany* a very readable journal Table layout is particularly good, and the line illustrations and plates are of a high standard Though all workers in the field of radiobiology will welcome this new outlet for their writings, one may hope that genetical and physiological journals will continue to receive contributions from those who have used radiations to elucidate problems primarily concerned with those sciences

Lanehead Field Centre

THE increasing scientific interest being shown in the 'marginal land' of the British Isles is reflected in the recent foundation of a new research centre in the Northern Pennines The Department of Geography of the University of Durham, under the guidance of Prof W B Fisher, has recently acquired a village school at Lanehead, near Cowshill, in Upper Weardale, and has speedily converted the building into an active centre for field research. Situated near the watershed of the Rivers Tyne, Wear and Tees, the new centre dominates a virgin area for field and ecological investigations Research projects have already been started on the geomorphology, microclimate, soils and vegetation of the region, and progress is being made in the analysis of the social life of the inhabitants of the Upper Pennine Dales In addition to giving field courses to the undergraduates of the University of Durham, the research workers (mainly postgraduate students) hope to add, in some way, to our knowledge of the social and environmental background for future development in highland Britain Many aspects of the background still perplex the technologist and the economist, it is hoped that Lanehead Field Centre will provide at least some of the answers

Rutgers Center of Alcohol Studies

THE Center of Alcohol Studies, which was instituted at Yale University in 1921, is being transferred to Rutgers, The State University, and will be known as the Rutgers Center of Alcohol Studies The transfer of the Center, internationally known for the study of alcohol in its social, biological, psychological and sociological aspects, is being made possible by a grant from the National Institute of Mental Health It is expected that the transfer of the Center, which at Yale has been identified with the Laboratory of Applied Biodynamics, will be completed by the spring of 1962 At Rutgers the new Center will be a unit within the Graduate School of the University, the dean of which is Dr Marion A Johnson The principal functions of the Center will include (1) Research into various problems involving the use of alcohol, physiological, psychological, sociological and economic (2) Teaching of groups with a special interest in problems of alcohol such as clergymen, public health officers, personnel workers, police, social workers, and nurses This will be done in a summer programme, the Yale counterpart of which has been nationally famous for years (3) Documentation of all forms of study dealing with alcohol (4) Publication of literature dealing with the subject, including the *Quarterly Journal of Studies on Alcohol*

Courses in Nuclear Energy

The European Nuclear Energy Agency of the Organization for Economic Co-operation and Development (recently the Organization for European Economic Co-operation) has published a new edition of its *Catalogue of Courses on Nuclear Energy in O E E C Countries, 1961–1962* (Pp 167 Paris Organization for Economic Co-operation and Development, European Nuclear Energy Agency, 1961) The *Catalogue* is designed to help science and engineering students who wish to acquire a better knowledge of nuclear subjects and to find out what training facilities are available University authorities and others wishing to compare the programmes of technical establishments in different countries will also find much relevant information The new *Catalogue* covers the 1961–62 academic year and gives details of training courses in subjects relating to nuclear energy in some 180 Western European universities, technical high-schools and research centres It contains a list of establishments where courses are given on subjects relating to nuclear energy, syllabuses of the main courses on nuclear physics, chemistry and engineering, with details as to lectures, length of courses, terms of admission and diplomas obtainable, and information concerning the principal items of nuclear physics and engineering equipment available for training in each establishment Copies of the *Catalogue* can be obtained on application to the Organization for Economic Co-operation and Development, European Nuclear Energy Agency, 28 Boulevard Suchet, Paris 16

Museum of Comparative Zoology, Harvard College

The one hundred and first annual report of the Museum of Comparative Zoology at Harvard College for 1959–60 records the celebration of the centenary of the founding of the Museum by Louis Agassiz Sir Julian Huxley gave a public lecture, and this was followed by a reception and a dinner The Museum is an integral part of a major university and still maintains research and teaching, which were the main objectives of Agassiz's life Although no major expeditions were sponsored during the year 1959–60, many trips were arranged by members of the staff for field and museum studies and for the collection of materials A long list of publications by the staff is an indication of the great amount of research undertaken

Cyrillic Transliteration

Scientific Information Notes for August–September (3, No 4, 1961) reports that progress toward agreement on the use of a compromise system for transliterating Russian (Cyrillic) characters into the Latin alphabet was achieved at a meeting of representatives of scientific and engineering societies, editors, publishers, librarians and Government agencies on July 14, 1961, in Washington, D C The meeting was convened by the American Association for the Advancement of Science at the request of the National Science Foundation to discuss the adoption of a single, uniform transliteration system for Russian to English The compromise system, tentatively designated as the "AAAS Transliteration System", combines features of the various systems now in use so that the transliteration of Cyrillic to Latin alphabets may be standardized An important consideration of the proposed transliteration system was that it could be typewritten with the minimum use of diacritical marks Systems considered in effecting the compromise were the systems of the Board of Geographic Names, the British Standards Institution, the Library of Congress–American Library Association and the International Standardization Organization The importance and volume of Soviet scientific and technical literature have resulted in extensive efforts to translate Russian material into English The multiplicity of transliteration systems in use has resulted in increased burdens for members of scientific and technical communities, editors, publishers, librarians and Government agency personnel Much confusion existing in this field could be alleviated or avoided by a reduction of the number of varying transliteration systems now in use The tentative system has been forwarded to the *Z*-39 Subcommittee on Transliteration of the American Standards Association It is expected that an *ad hoc* *Z*-39 subcommittee will be formed to deal with the problem of Russian transliterations.

Learning Theory and the Therapy of Neurosis

Monograph Supplement No 13 of the *British Journal of Psychology* (Cambridge University Press, 1961. Pp. 29 7*s* 6*d* net) is entitled "Learning Theory and the Therapy of Neurosis" The author of this clear and admirably concise monograph, Mr. Ralph Metzner, provides a useful review of the literature on avoidance training and experimental neurosis in animals, and examines its relevance to some aspects of human psycho-pathology He is particularly (perhaps excessively) concerned to analyse some recent methods of psychological treatment (so-called 'conditioning therapy') and to indicate their kinship with the animal training procedures Although a comparative approach to behaviour and its disorders is to be welcomed, it might seem important to bear in mind the differences as well as the resemblances between animals and men. This the author signally fails to do As a result, his work will appear to many as a gross over-simplification of the problem of neurosis and as singularly lacking in awareness of clinical reality None the less, it has value as an unusually fair and thoughtful account of experimental work in its field and as a timely reminder that psychotherapy must eventually achieve a rational basis

The Textile Institute

The following awards have been made by the Textile Institute *The Institute Medal,* to Mr K W L Kenchington, senior development officer, Directorate of Stores and Clothing Development, War Department, Royal Aircraft Establishment, Farnborough, for his contributions to the Institute in the field of clothing science and technology, *Service Medal,* to Mr P H S Bell, head of the Department of Textile Industries, Huddersfield College of Technology, and to Mr J Boyd, of Courtaulds, Ltd , *Companionship,* to Mr C. E Harrison, president of the Federation of British Industries, and to Mr F M Stevenson, chairman and managing director of Stevensons (Dyers), Ltd , and Associated Companies.

Fulbright Travel Grants

Under the provisions of the Fulbright programme, travel grants are available to citizens of the United Kingdom and dependent territories to go to the United States of America for academic or educational purposes, provided that they have adequate financial support in dollars for the period of their visit, and have been accepted by an American institution of higher learning for a minimum of nine months The grants cover the cost of direct travel between a candidate's home and the American institution or university They are available during June 1–August 15, 1962, for which applications must be received before March 16, 1962, and August 16, 1962–April 1, 1963, for which applications must be received before June 1, 1962. Application forms and further information can be obtained from the United States Educational Commission in the United Kingdom, 71 South Audley Street, London, W 1

University News .

Birmingham

The following appointments have been announced *Lectureships*. R G. Bird (civil engineering), Dr. J. S Hough (senior lecturer in charge of the Sub-Department of Malting and Brewing in the Department of Biochemistry), A W Kwiatkowski (mechanical engineering), G Martelli (physics), Dr L Riddiford (senior lecturer in the Department of Physics), Dr K R Rushton (civil engineering), Dr. R B Shearn (chemical engineering), N B W Thompson (physical metallurgy) *Research Fellowships*. T Duthie (Wilmot Breeden Fellow in the Department of Mechanical Engineering), Dr H Kaliszer (mechanical engineering), B K Gazey (electrical engineering), R J Heitzmann (chemistry), Dr A E Pedler and Dr C A Barson (senior Research Fellows in the Department of Chemistry), Dr. B Henderson (physical metallurgy), G R Orgam (industrial metallurgy), B Walker (industrial metallurgy) Dr S Swierszczewski (nuclear physics), J R Turcan (engineering production), C J H Williams (James Watt Research Fellow in the Department of Mechanical Engineering)

Leeds

Mr G L Bibby and Dr A E. D Heylen have been appointed to lectureships in the Department of Electrical Engineering, and Dr M Holmes to a lectureship in the Department of Civil Engineering

Liverpool

The City of Liverpool College of Technology has been admitted to affiliation with the University of Liverpool for a period of three years from October 1, for the purpose of teaching pharmaceutical chemistry for courses leading to the ordinary degree of B Sc and to the degree of B Sc with honours in pharmacology During the period of this affiliation the head and four members of the Department of Pharmacy of the College staff will be recognized as teachers of the University

London

The title of professor of social statistics in the University of London has been conferred on Mr C A Moser in respect of his post at the London School of Economics and Political Science

Manchester

Prof P J Collard, of the University College of Ibadan, has been appointed professor of bacteriology and director of the Department of Bacteriology in succession to Prof H B Maitland Prof Collard will take up his duties in April 1962

College of Aeronautics, Cranfield

Dr R L Apps, of Atomic Power Construction Ltd , has been appointed to the post of lecturer in the Department of Materials, Mr A G. Simms, lecturer at Leicester College of Technology, has been appointed to the post of lecturer in the Department of Production and Industrial Administration, Mr J W Mair has been appointed Research Fellow in the Department of Materials, Dr A Younger, of Richard Thomas and Baldwins, Ltd , has been appointed Research Fellow in the Department of Materials

Announcements

Prof J C Mitcheson, professor of mining at the Royal School of Mines, Imperial College of Science and Technology, and a member of the Geological Survey Board since 1959, has been appointed chairman of the Board in succession to Sir Walter Drummond

Mr B N Hughes, at present editor of *Technology* and special writer to *The Times* on technical and technological education, has been appointed a director of Messrs. Chapman and Hall, to succeed the late Mr Geoffrey Parr as chief editor for scientific and technical books

A symposium on "Low Temperature Carbonization of Non-caking Coals and Briquetting of Coal Fines" is being organized by the Regional Research Laboratory, Hyderabad, India, during November 20–22 Further information can be obtained from the Director, Regional Research Laboratory, Uppal Road, Hyderabad 9, A P , India

The Anatomical Society of Great Britain and Ireland will hold its annual general meeting at St Mary's Hospital Medical College, London, during November 23–24 The meeting will be devoted to papers on "Cytology of Nervous Tissue". Further information can be obtained from the secretary, Prof R J Harrison, Anatomy Department, London Hospital Medical College, Turner Street, London, E 1

The British Insecticide and Fungicide Conference will be held at Brighton during November 7–10, under the auspices of the Association of British Manufacturers of Agricultural Chemicals Further information can be obtained from Mr. W. A Williams, secretary, Association of British Manufacturers of Agricultural Chemicals, Cecil Chambers, 86 Strand, London, W.C.2

NEW SOURCES OF ENERGY

THE United Nations Conference on "New Sources of Energy" was convened for the exchange of experiences and new ideas on recent progress in the applications of solar energy, wind power and geothermal energy, and held in Rome during August 21–31 The term 'new' is not perhaps the best description of these sources of energy which have been used by humanity for many centuries, and is used to emphasize that their development has been largely ignored or regarded as uneconomical in the past but that they should now be included in any survey of power resources These three forms of energy are very different in their characteristics, a geothermal energy source is a gift for any nation fortunate enough to possess such a site, for although there are many problems involved in harnessing this form of energy, its utilization follows well-established procedures Solar and wind energies are ubiquitous, though varying in intensity in different localities and at different times, they are both 'low intensity' sources having a maximum energy flux of the order of 1 kW /m ^{2} The latter, however, is in the form of mechanical energy for which Nature has paid the toll of the Carnot cycle efficiency. while the former is in the form of heat, and mankind must pay the toll to convert this to mechanical or electrical energy Consequently, although the conversion of solar radiation to electrical power on a small scale would be advantageous, the major form of utilization should be as heat at low or high temperatures as required

It is not possible to make detailed comment here on the technical proceedings at a conference attended by some 650 delegates from more than fifty countries and at which some 250 papers were presented, about half being on applications of solar energy All the papers were summarized by *rapporteurs* in sections; these reports were discussed later and a final summary was given at the concluding session for each form of energy under consideration Two visits were arranged during the conference. One was to a demonstration of a solar power plant, 2–5 kW capacity, designed by the National Physical Laboratory of Israel This uses air-inflated plastic mirrors and covers in the form of cylinders about 12 m long which are aligned east and west, and only need moving occasionally to allow for the seasonal change in the position of the Sun Steam is produced at a temperature of 150° C and the heat transferred in a storage vessel to vaporize an organic working fluid which is expanded in an impulse turbine, condensed and returned to the heat exchanger This design has been reduced to the simplest essentials and has an estimated cost of 1,000 dollars per kW installed, and a power cost of 5 cents per kW hr based on 6 per cent interest rate and 15 years life The other visit, of contrasting nature, was to the geothermal station of Larderello This power system, in use before the Second World War, has now been extended to a capacity of 2×10^9 kW hr annually, using steam at an average pressure of 5 atmospheres absolute and a temperature of 200° C The first impression is the unusual sight of gigantic cooling towers rising from surrounding countryside, with a relatively low power-house and a maze of snake-like pipes conveying steam from the distributed bore-holes Use of geothermal steam is complicated by the high gas and mineral content of the steam, so that most of the power stations operate by heat transfer to a pure water circuit from which the steam is passed to the turbines This simplifies the gas removal problem and provides for effective recovery of the minerals, mainly boron compounds Conference papers were presented on the recent developments in the use of geothermal power in New Zealand and Iceland, as well as prospective applications in Japan, South America and other volcanic zones

Wind-power units of small output are well established in agricultural regions The problems involved in larger units of 100–500 kW. which could generate electricity for a grid supply are still under investigation, but the tendency would appear to be towards a direct-drive propeller unit geared up to the generator by mechanical or hydraulic transmission and with automatic voltage control

The papers on solar energy applications covered many fields, such as water and house heating, crop drying, distillation, power production by thermal cycles, refrigeration, air conditioning and cooking The direct conversion of radiation to electricity by thermocouples, photo-voltaic cells and thermionic devices was also discussed, and recent developments in solar furnaces Details of these processes were described more fully in my report on the World Symposium on Applied Solar Energy, Arizona, 1955 (*Nature*, 177, 110, 1956) Since that date there has been development in new designs and improved equipment, especially as regards economical construction, but no really new principles have emerged The number of large-scale installations for water heating and distillation at present existing remains very small, and there is still insufficient detailed information available to select the most satisfactory designs for various purposes. Most of the designs in the fields mentioned above have been developed independently, and are still in the experimental stage Large-scale commercial developments seem limited to water heaters in Israel, and some large-area solar-stills in the United States One of the proposals given prominence at the conference was that a series of experimental stations should be established in various countries where the scaling up from the experimental models to the larger industrial installations could be developed and in this connexion mention should be made of the Brace Experimental Station at Barbados, West Indies, recently established by McGill University The extensive funds available for research on space travel and artificial satellite powering will make possible the development of many schemes for the direct production of power from solar radiation which can be adapted for terrestrial use

Perhaps it will be more profitable in the space available to discuss the economic and social implications of solar energy utilization Much of the discussion at the conference concerned the under-developed nations, which might be described more politely as non-industrial, and how these could be helped by the industrial nations One possible procedure suggested would be for the industrial countries to manufacture and sell equipment to the non-industrial countries, but individuals could not afford to purchase such equipment without a national subsidy in the first instance The preferred alternative would be for the industrial countries to develop very simple designs of equipment which could be made in the country where required and thereby establish village industries The first stage might well be along communal lines in villages, for baths, refrigeration and electricity generation, rather than attempting to accomplish these for individual dwellings The importance of simplicity was emphasized, since in solar appliances the capital cost per unit of energy collected is more significant than the thermal efficiency of conversion The sociological feature is the difficulty of introducing a new method of doing something already accomplished by other means, for example, to replace refuse-burning cookers by solar cookers, but where the application is completely new, as for electricity generation or refrigeration, there is not the resistance of tradition

As regards industrial countries, solar energy can only be integrated with other energy sources, and water heating is the most feasible application The prospects of success are greatest in the Mediterranean countries, decreasing but not necessarily being non-existent in the more temperate countries Much consideration was given to the assessment of potential resources in all the fields of energy considered These data are particularly lacking as regards solar radiation and a much closer network of recording stations is required to assess the availability on a micro-climatic basis

The final conclusions would appear to be

Geothermal power is analogous to hydro-power, and obviously should be developed in the few localities where such sources exist, provided that the power can be transmitted to centres of population Wind-power is an established factor in agricultural areas but development is needed before large wind-power generators can be constructed Utilization of solar energy is the most difficult of all to establish Protagonists must have faith in the possibilities, some of which are not yet proved Similar situations have, however, arisen in other technologies now fully established and justified, for example, space travel, where the initial difficulties have eventually been overcome as unforeseen developments occurred The urgent needs are international co-operation to establish satisfactory designs of equipment and the training in Europe and the United States of personnel from the user nations who can return to promote investigations in their own countries

The general impression is that the development in six years is not as great as would have been expected It is, however, encouraging to find that there are many people of high academic ability in various countries who have enough faith to devote their whole, or at least a considerable proportion, of their time to the attainment of a deeper knowledge of the underlying principles of all these sources of energy and in particular of solar energy devices, in order to raise the existing standard of living in under-developed countries Co-ordinated planning during the next six years should promote a significant increase in applications

Long-term predictions for the future are necessarily uncertain, but there is no doubt that energy demands will grow more rapidly than the world population, which is expected to double by the year 2000, and that all sources of energy should be actively investigated and integrated The conference and discussions arising will undoubtedly promote these objectives, and lead to more successful international co-operation in future developments H HEYWOOD

MICROWAVE MEASUREMENT TECHNIQUES

A CONFERENCE on the general subject of microwave measurements was held at the Institution of Electrical Engineers during September 6–8 A large audience of scientists and engineers from many countries assembled to consider some fifty papers covering all aspects of modern microwave measurement

In his introductory lecture, Prof H E. M Barlow, of University College, London, stated that microwave measurement techniques could be grouped broadly under the following headings measurements using field probes, measurements depending on resonance arrangements, attenuation and phase shift measurements, noise measurements and power measurements, and that the general limits of accuracy of microwave measurements at the present day were of the order of ± 0 1 per cent for impedance measurements, ± 1 per cent for power measurements, and about ± 0 01 db up to 3 db for attentuation measurements

Subsequent sessions of the conference considered most of these groups in detail

Prof Barlow also described two new devices utilizing the Hall effect for microwave power measurement In the first, a thin indium arsenide crystal is rotated continuously in a wave-guide The resulting Hall E M F in the crystal is thus modulated at the rotation frequency, unlike the parasitic thermoelectric and rectified E M F s occurring at the crystal contacts, from which it can therefore be separated by a filter The second device was demonstrated, and comprised an array of Hall crystals in cascade which could be used to measure high-power densities in free space The multiplicity of crystals helps to cancel out the unbalanced rectifier effects occurring at the contacts

A supporting paper by R E Larson of the Boulder Laboratories of the U S National Bureau of Standards outlined the calibration facilities offered by the Electronic Calibration Center of the Bureau. These are ultimately intended to cover the measurement of power, impedance, frequency, attenuation and noise over the full frequency-range 300–40,000 Mc /s

An interesting paper by Prof C. Susskind and P O Vogelhut, under the title "Cavity-perturbation Measurements of the Effect of Microwave Radiation on Proteins", described experiments concerned with the biological effects of microwave radiation on living animals Irradiating power densities of the order of 0 1 W /cm ^{2} produce significant changes of body temperature in mice, and accordingly the 'tolerance' level for human beings is accepted as 0 01 W /cm ^{2} Apart from the heating effect, microwave irradiation causes other biological changes—in particular, it brings about a change in the hydration-rate of proteins The measurement problem involved is one of determining the values of complex permittivities of the order of 60 + 30 j, within times of the order of milliseconds These are found by measurements of the Q and resonant-frequency shift of a resonator through which the sample is passed at a constant rate

J E Pearson and J A Jane of the Radio Research Station (Department of Scientific and Industrial Research) underlined the need for power density monitors to measure power densities of the order of 1–20 mW /cm ^{2} for health hazard purposes Calibration of such meters requires a source of microwave energy of known power density and the authors described such a source utilizing parallel plate transmission line for frequencies between 0 3 and 1 5 Gc /s

Further papers presented on the first day dealt mainly with the measurement of impedance, admittance and reflexion coefficients, although papers dealing with noise measurement and problems of measurement associated with travelling wave tubes were also included The former group of papers was largely concerned with the less-conventional types of measuring equipment reflectometers, rotary standing wave indicators and 3-probe lines, together with an equipment for instantaneous impedance measurement described by P. Hargrave and S J Robinson of Mullard Research Laboratories, which utilizes seven coaxial hybrid rings, capable of giving the polar components of an impedance directly to within ± 10 per cent

On the second day the subject of power measurement was reviewed in an introductory paper by Prof A L Cullen of the University of Sheffield The present position could be broadly summarized by stating that most instruments for the measurement of microwave power are accurate to within about ± 2 per cent, although considerable difficulties still exist in providing reliable apparatus for the measurement of small powers, particularly at the higher frequencies Among hitherto unutilized effects suggested by Prof Cullen which might find application in future power-measuring devices were the use of electrostrictive and magnetostrictive materials to convert electromagnetic field energy into mechanical movement and the use of the saturation-level of maser-type devices, which occurs with increased pump-power, as a reference standard A further similar scheme, using second-order saturation effects in ferrites, was put forward as being possible by Dr P J B Clarricoats of the Queen's University of Belfast Prof Cullen also suggested that it should be possible to make a wattmeter depending on the detection of the change of electromagnetic angular momentum occurring when circularly polarized waves are incident at a conical surface

"A Survey of Microwave Power Measurement Techniques employed at the National Bureau of Standards (U S A)" was presented by G F Engen, who dealt in detail with problems of bolometric measurement errors and mount efficiency.

J A Lane gave a "Comparison of Power Measuring Standards at Microwave Frequencies", indicating that measurements of the efficiency of numerous bolometer mounts conducted in various countries, whether determined by microcalorimeters, film bolometers, impedance measurement or torque vane wattmeters, were all in good agreement at power-levels of the order of 1–2 mW The latter three methods exhibited errors generally of the order of ± 1–2 per cent, while rather better accuracy was possible with the microcalorimeter

An interesting new instrument for the measurement of power was described by Dr E Acs of Budapest The power to be measured is absorbed in a film bolometer element terminating a waveguide and the consequent heating of the surrounding air causes air convection currents in an adjacent channel The convected air stream impinges on a vane, the resulting deflexion of which is dependent on the power dissipated in the film.

Further papers by Prof Barlow and D Woods of the Ministry of Aviation described respectively a suggested method for the measurement of high-frequency power using a thin crystal of indium antimonide placed edge-on to the incident wave (it can be shown that in the absence of reflexions from the crystal edges the Hall voltage is directly proportional to the transmitted power), and a coaxial millivoltmeter/milliwattmeter which uses a silicon diode to measure voltage and power to within 0 5 per cent and 1 5 per cent, respectively, at all frequencies from d c to 1 Gc /s

L. Lewin and G H. B Thompson of Standard Telecommunication Laboratories, Ltd , introducing the afternoon session, read a paper emphasizing the difficulty of "Measurements in Microstrip" The reasons for the present unsatisfactory state of affairs are first, the lack of a simple theory on the basis of which components can be designed and, secondly, no satisfactory insertion type detector yet exists.

Two papers presented by R J Turner of the Post Office Research Station (one in collaboration with D L Lisney) covered equipment used for the measurement of group delay and insertion loss of wave-guide networks in the 3 8–4 2 Mc /s band for use in the testing of components for microwave links used for multi-channel telephony and television transmission Other papers dealt with the measurement of wave-guide attentuation, measurement of dispersion of disk-loaded wave-guide and of propagation coefficients in wave-guides with unknown but symmetrical input and output coupling Among a group of papers devoted to attenuators, a paper on "Resistive Attenuators and their Calibration", by D A J Walliker of Decca Radar, Ltd , dealt specifically with the use of metallized glass vanes and their mounts Such attenuators with micrometer adjustment can yield accuracies of 0 04 db /micrometer division at 40-db level in size 10 guide, with resetting accuracies up to an order of magnitude better than this An attenuator of this type in size 16 guide has retained its calibration within ± 0 03 db over a five-year period of laboratory use Practical calibration systems for S and X band attenuators and their general specifications were also described

The final morning was devoted specifically to millimetre wave techniques, the papers presented falling into two distinct groups, namely, those concerned with H_{01} circular wave-guide transmission and those concerned with other topics The former group included a paper by R Hamer and R J Westcott of the Post Office Radio Research Laboratory on the measurement of attenuation in short lengths of circular guide The Q factor ($\sim 10^6$) of a length of guide under test, when used as a resonator, was measured by comparing the resonator response curve when excited by a swept frequency oscillator with that of a standard reference resonator of lower Q The response curves of the two resonators are matched by adjustment of the display sweep frequency and amplitude, the attenuation constant being deduced from the readings of the attenuators used to achieve this control. The ratio of measured to theoretical attenuation for plain copper guide and copper or aluminium helix guide was of the order of 1·4 at 35 Gc./s. for a 2-in. diameter guide in all cases.

R. F. Skedd of the Standard Telephone Laboratories discussed the generation, and measurement of attenuation, of unwanted modes associated with long-haul wave-guides, while a paper by Dr. A. E. Karbowiak, G. Craven and V. H. Knight of the same establishment described an equipment for the automatic recording of wave-guide attenuation. This apparatus was capable of recording the variation of attentuation with frequency over the whole of the 40–80 Gc./s. band in a space of about ½ hr.—an operation which, without the degree of automation used, would require some thousands of independent sets of measurements. An additional paper by Dr. Karbowiak and Mr. Skedd was concerned with an instrument for the accurate determination of relative surface losses in the millimetric band.

Among the other papers, Dr. J. Brown and Dr. A. P. Anderson of University College, London, dealt with the use of a single crystal as a harmonic generator and as a detector at a wave-length of 4 mm. Such an arrangement with the addition of a simple ferrite modulator has been used to measure the impedance of wave-guide components at 4 mm., as well as to determine the permittivity of liquid dielectrics.

W. L. Birch of the General Electric Co. Hirst Research Centre described a milliwattmeter capable of detecting changes of power ~ 10 μW. for the 70–80 Gc./s. band in which the power to be measured is absorbed in a carbon load, the temperature rise in which is detected by a thermopile with which it is in thermal contact. A further wattmeter for use at millimetric wave-lengths was demonstrated by Dr. H. A. French of A.S.W.E., Portsdown, and Prof. A. L. Cullen. The instrument was of the oscillating torque vane type, was capable of measuring power as low as 100 μW., and, like its predecessors, was also capable of absolute calibration.

The construction of Fabry–Pérot interferometers and their use for the measurement of permittivity of such substances as TiO_2 was then considered in two papers by Dr. W. Culshaw and M. V. Anderson of General Telephone and Electronics Laboratories Inc., California, and by Dr. J. S. Seeley and J. C. Williams of Queen Mary College (University of London).

The final session was concerned with measurements on materials. Prof. Barlow described a method for the measurement of permittivity of high-loss dielectrics in which the specimen under test was located in an evanescent guide coupled to a resonant cavity, thus avoiding the disturbance of the field which normally results when the specimen is located within the cavity. For dielectrics with small losses Prof. G. B. Walker and S. P. Luthra of the University of British Columbia used 'ghost modes' for the determination of complex permittivity. A disk specimen of the dielectric is located in a wave-guide and a resonant mode of the specimen—the 'ghost mode'—is excited, the latter being a mode in which the fields outside the specimen are strongly evanescent and thus contain little stored energy. The limitations of the technique were discussed and a further paper by Prof. Walker and Messrs. J. M. Free and M. E. B. Moffat of the University of Oxford showed how these as well as normal cavity techniques could be used for the investigation of the properties of titanium dioxide and magnesium titanate ceramics at *S*, *X*, *J* and *Q* bands. Dr. Hamer and Mr. Westcott described a method of measuring the complex permittivity of dielectric films while R. B. Nichols and A. E. Brown of Elliott Bros. spoke about an apparatus for grading dielectric cubes according to their exact permittivity. The cubes, used for the fabrication of Luneberg lenses, possess permittivities lying between 1 and 2 which are determined by noting the position at which resonance occurs, as a movable plunger sweeps the cube through a test cavity. Further papers by Dr. Clarricoats and by C. P. Aron of Morganite Research and Development, Ltd., described a simple wave-guide method for the determination of the permittivity of cylindrical dielectric rods and an apparatus for the measurement of the tensor susceptibility of ferrite materials.

G. D. SIMS

PROGRESS IN MICROCHEMICAL METHODS AND TECHNIQUES

THE 1961 International Symposium on Microchemical Techniques, organized by the Metropolitan Microchemical Society of the United States under the sponsorship of the Commission on Microchemical Techniques, Section of Analytical Chemistry, International Union of Pure and Applied Chemistry, was held during August 13–18, at Pennsylvania State University, University Park, Pennsylvania. The excellent accommodation and facilities made possible an informal atmosphere of fellowship and individual contacts. The purpose of the symposium was to provide a forum for the interchange of information and ideas among technologists from all parts of the world concerning new methods and techniques or unique applications of microchemical or microanalytical interest.

The symposium was inter-disciplinary both with respect to the interests of the almost five hundred technologists attending and the technical programme of ninety-five papers and lectures. The symposium was truly international in character with more than twenty countries represented. Travel of many speakers to the United States was supported by a generous research grant from the National Institutes of Health, U.S. Public Health Service.

The technical sessions and plenary lectures were supplemented by a three-day commercial exhibition of equipment, apparatus, specialities and literature, by six panel discussions, film sessions on the history of microchemistry and research advances, a practical demonstration session, a popular lecture, and by various social events.

The plenary lectures were of salient interest. H. Lieb (Austria) delineated the history of microchemical techniques and A. A. Benedetti-Pichler (United States) the development of microchemistry in the United States. D. Van Slyke (United States) surveyed the evolution of micro-gasometric methods of analysis, a field in which he has long pioneered. E Sawicki (United States) considered the present status of micro methods for the sensitive and selective detection and determination of aldehydes and aldehyde-yielding substances, emphasizing his own successful studies R Belcher (England) examined methods developed for the determination of elements and functional groups in organic compounds using sample weights of 30–50 μgm , an area in which he and his co-workers have made notable advances N D Cheronis (United States) discussed the challenges encountered in the characterization of organic compounds at the microgram and especially the submicrogram range It appears that many characterization reactions are so slow at concentrations less than about 10^{-5} molar that operationally they may be considered as not occurring The technical papers covered the entire gamut of microchemical and microanalytical interests, and, in almost all cases, presented novel and previously unpublished research findings

A special session on thermo-microscopic methods due to L Kofler was prefaced by a short talk by A Kofler (Austria), which reviewed the course of her husband's hot-stage experiments A. Lacourt and N Delande (Belgium) reported an extended investigation of the identification of some sixteen amino-acids by the hot-stage observation of eutectic temperatures with twenty-five different components, of which oxalic acid and dicyandiamide appear especially good Of the general papers on microscopy, that of L W. Gamble (United States) was especially noteworthy, it introduced a new approach for the characterization of aliphatic hydrocarbons, namely, microscopic study of their crystalline urea and thiourea adducts E Wiesenberger (Germany) described how the electron microscope could be used somewhat analogously to the light microscope for the detection of substances via the observation of chemical reactions The reactions, largely precipitation of metal ions with suitable reagents or electrical or chemical reduction to metals, are conducted on the special carriers used in electron microscopy within a field of 0 004 mm ^{2}. E. Waldmann (Switzerland) considered the systematic differentiation and identification of crystalline deposits in body tissue by microscopic tests

Inorganic microanalysis was represented by many significant papers. Those of H Flaschka and P O Sawyer (United States) and of A. Ringbom (Finland) emphasized the value of photometric titrations for metal ions present in small amounts or at extremely low concentrations using either ethylenediaminetetraacetate or a chelating chromogenic agent as titrant Sawyer and Flaschka also described an elegant micro- and ultramicro-phototitrator using as the light-sensing element a commercial semi-conducting photodiode responding in such a small angular range that titrations may be performed in open daylight. J Zýka (Czechoslovakia) recommended lead tetraacetate as an oxidizing titrant for the potentiometric titration of various metals and organic compounds in acetic acid or in an aqueous medium containing mineral acid. R. Přibil and F. Vydra (Czechoslovakia) based a simple oxidimetric microtitration of cobalt on the finding that iron(III) oxidizes chromium(II) in the presence of 1,10-phenanthroline or 2,2′-bipyridyl, which also masks many interfering cations by complexation. L Erdey and G Svehla (Hungary) described the chronometric determination of metal ions based on their catalysis of suitable reactions in which the elapsed time is recorded between mixing and the appearance of the Landolt effect, the peroxide–iodide reaction permits the determination of 0 1 μgm of molybdenum within 99 per cent accuracy

Quantitative elemental organic analysis, as a major subject for microchemical research, was considered in many papers In the combustion analysis for carbon, hydrogen and sulphur, C Maresh and co-workers (United States) proposed a gas chromatographic finish. H Malissa and E Pell (Austria) reported on their recent investigations on the complete automation of the micro-determination of carbon, hydrogen and sulphur A M G Macdonald and Y Gawargious (England) gave the results of a comparative study of various high catalytic fillings in the combustion analysis for carbon and hydrogen, cobaltic oxide appeared to be the most satisfactory for general work J A Kuck and co-workers (United States) described an instrumented combustion method for carbon and hydrogen in which carbon dioxide is assessed by infra-red absorptiometry and hydrogen by thermal conductivity

G Ingram (England) introduced a direct ignition in an oxygen-filled chamber at 850° C for the determination of carbon, hydrogen, halogens and sulphur, the combustion products are swept into appropriate absorbing reagents and determined. The method requires only 30 min or less per sample and is applicable to difficult materials, such as organic fluorine or phosphorus compounds W G. Guldner and A L. Beach (United States) based a rapid micro determination of oxygen on pyrolysis of the organic sample in a helium stream in an induction-heated graphite crucible and oxidation of the carbon monoxide, after trapping of unsaturated compounds, to carbon dioxide, which is absorbed in barium hydroxide solution and determined conductometrically J. L. Brownlee, jun (United States), presented an intriguing approach to the determination of oxygen in organic compounds involving a neutron-induced reaction in an atomic reactor, namely $^{6}\mathrm{Li}(n,\alpha)^{3}\mathrm{H}$, $^{16}\mathrm{O}(t,n)^{18}\mathrm{F}$; fluorine-18 is separated and determined radiochemically

Noteworthy papers in organic functional group analysis included that of J E. Zarembo and M. M. Watts (United States) on the determination of the carbodiimide function, of E Sawicki and co-workers (United States) on a highly sensitive spectrophotometric determination of azuelene, and of W Merz (Germany) on the determination of active hydrogen using alkyl-substituted metal aluminium hydrides C A Rush and J I Miller (United States) proposed barium isopropyl methylphosphonate as a rigorous reference standard for carbon, hydrogen, phosphorus, barium and alkoxyl S R Palit and P Ghosh (India) based a determination of acids, bases and salts at micromolar concentrations in benzene on the colour behaviour with rhodamine and certain other dyes previously extracted by benzene under specific conditions M. Bobtelsky (Israel) considered his recent research work with microheterometry in work on the reactions and nature of large organic molecules, including dye lakes and metal–protein complexes

Physical measurements on the micro scale also received attention The use of a dynamic flow technique in place of the usual static drop method was recommended by C. L Ogg and co-workers (United States) for the thermistorized determination of molecular weight W Simon and co-workers

(Switzerland) described refined thermistor circuitry and instrumentation for the routine, precise determination of molecular weight using a sample weight of only 2 5 mgm for a molecular weight of 500 P D. Garn and J E Kessler (United States) demonstrated that thermal analysis is feasible for sample weights less than 1 mgm by the use of appropriately designed sample holders

In the session on nucleonics, G F Morrison and J F Cosgrove (United States) described the application of neutron activation to the sensitive determination of the copper activator in single crystals of electroluminescent zinc sulphide weighing less than 500 μgm. B A Thompson (United States) considered how radiochemical techniques and especially neutron activation could be applied to the determination of the principal components, trace impurities and thickness of metal films a few angstroms in thickness and one square centimetre in area, such films are encountered in the performance and design of electronic devices, including vacuum tubes M T Kelley (United States) reviewed the present status of the analysis of highly radioactive reactor fuels and spent products using liquid samples of 5–700 μl , coulometry, spectrophotometry, flame photometry, emission spectroscopy, titrimetry and radiometry, and density measurements are feasible by remote controlled, automatic or 'slave' manipulated operations A Holasek and co-workers (Austria) explained the difficulties and operational problems encountered in the synthesis of milligram amounts of fatty acids and esters labelled with carbon-14, and considered salient factors involved in the selection of suitable synthetic methods

Chromatographic methods were the subject of many interesting papers E. G Wollish (United States) considered critically the accelerating interest in alumina and silicic acid for thin-layer chromatography in the separation and identification of organic compounds, including drugs. H K Mangold and co-workers (United States) exemplified how thin-layer chromatography acts as a valuable analytical and preparative tool in lipid chemistry L S Ettre and W Averill (United States) demonstrated how new gas chromatographic instrumentation using capillary (Golay) columns and ultra-sensitive detectors permit the direct analysis of trace components in samples of micro-size, and set forth criteria for the selection of methods and instrumentation L Wiesner and W -J Schmidt-Kuster (Germany) described the gas-chromatographic performance of a new integrating counter-detector using a flow-type proportional counter containing a source of ionizing radiation and used with a suitable scaler T S Ma and M Gutterson (United States) recommended gas chromatography in the determination of several organic functional groups S Patton (United States) considered the identification of food flavours using a diversity of techniques including gas, paper and column chromatography, and the study of the dinitrophenylhydrazones of volatile keto-compounds Paper chromatography was applied by B Bobrański and L Syper (Poland) to the identification of drugs containing unsaturated radicals following reaction with mercuric acetate A K. Dey and E J Singh (India) explained the behaviour and application of various complexing agents in the separation of metal ions by the Weisz ring-oven technique

The contemporary position of small-scale methods in the teaching of chemistry at the secondary school and collegiate levels was assessed in a special session with speakers from Northern Ireland (C L Wilson, N N Gilpin), England (J B Headridge, H Holness), and the United States (N D Cheronis, T S Ma and J. A Kuck). A Steyermark (United States) considered the training of chemists in industry in quantitative organic analysis

When the *Proceedings* of this symposium become available as a single volume (Interscience, early 1962), the interested technologist will be able to ascertain the position of microchemistry and microanalysis for 1961 in the spectrum of scientific activity, and to comprehend the research trends that will yield the 'to-morrow' of these disciplines In brief, microchemical and microanalytical research faces continuing challenges with ever smaller samples, ever more minute components, coupled with demands for adequate accuracy, precision and rapidity Improved instrumentation, automation and new techniques and reagents, coupled with re-assessment of present methods and approaches, will energize further advances

JOHN Y STEEL

INSECT POLYMORPHISM

A SYMPOSIUM on polymorphism in insects, organized by the Royal Entomological Society of London, was held at the Imperial College of Science and Technology, London, during September 21–22 The president, Prof G C Varley, was in the chair at the first meeting and expressed a hope that special attention would be directed to the agencies promoting and controlling this type of variation

Prof O W Richards, in a general introduction, stated that polymorphism is very widespread among the insects and occurs in all the major orders The metamorphosis of insects, itself a mode of polymorphism, perhaps makes them especially prone to such variation There are two principal types of polymorphism the genetic type, where two or more genotypes co-exist in a state of balance, and the induced type, in which some variable environmental factor such as population-density, food, day-length or temperature leads to the development of two or more kinds of individual in a species

Dr E. B Ford, in an account of the theory of genetic polymorphism, stated that the standard examples are only special cases of a more general phenomenon which is often overlooked when the characters involved are not easily visible This is the tendency for selection to favour the heterozygote over both homozygotes when, after some change in the environment, a rare major gene begins to spread The favourable effects of the gene will tend to become dominant and the unfavourable ones recessive, and the heterozygote will have all the advantages and none of the disadvantages of the homozygotes. Where polymorphism results from the interaction of several genes, the whole complex is controlled by a supergene, the link between the units of which may be strengthened by a chromosome inversion The original effects of the controlling mechanism are always liable to evolutionary change by selection of the remainder of the gene-complex

Dr P M Sheppard then reported on recent work on polymorphic mimetic swallowtail butterflies Knowledge of the way in which mimicry arises and is maintained makes possible a number of predictions as to how the polymorphism should be controlled genetically These predictions can then be compared with the genetics of the polymorphic mimics so far as these have been unravelled The most striking results have been obtained in the African *Papilio dardanus*, in which several different forms of female, some mimetic and some not, correspond to a single type of male Recently, methods have been devised for breeding the butterfly artificially in England and a genetic analysis combined with field data on population statistics show a good agreement with theoretical predictions

Prof T Dobzhansky dealt with the dynamics of chromosomal polymorphism in *Drosophila* In the giant chromosomes of the larval salivary glands one can recognize individuals which as a result of inversions of parts of chromosomes have different gene arrangements Several chromosomal types may occur in one population and their proportion may be constant, vary seasonally, or over longer periods, or geographically Such changes in proportion may directly demonstrate the action of natural selection and allow calculation of the selective advantages of the polymorphs The mere order of the genes may itself be an element in the fitness of a polymorph, but perhaps more often an inversion by suppressing crossing-over preserves an arrangement which gives an advantage to heterozygotes Several of the field phenomena can be reproduced in cage populations. The proportions of the polymorphs are easily modified by changes in the environment or in the genetic background Crosses with stocks from widely separated sources have an unpredictable effect on the proportions of the inversions because of the large number of alternative backgrounds provided

The next four contributions were concerned with familiar examples of non-genetic polymorphism, namely, in Hymenoptera, in termites, in aphids and in locusts Prof C D Michener dealt with the first topic and showed that in only a few bees and in ants is the worker caste sharply different from the queen In most social bees and in wasps the differences are slight and overlapping, occurring mainly in behaviour and physiology, but in several ants the worker caste is itself polymorphic. In the least differentiated castes of some halictine bees, the slight differences arise in the adult stage but the castes of all other Hymenoptera, except perhaps *Melipona*, seem to depend on differences in nutrition, sometimes interacting with temperature At some point in development, however, the caste becomes determined In *Pheidole*, the workers produced from a queen's first batch of eggs are small, even if they were well fed, the type of worker is thus determined in the egg, but perhaps here through the nutrition of the queen which laid them The selective advantages of the castes of advanced insect societies is clear but their evolution is anomalous, since the first step seems to be the reduction of fertility in some individuals However, it appears that economy of labour and better defence of the nest make even the most primitive social organization (one queen and one worker in some halictine bees) more viable than isolated queens.

Dr M Luscher gave an account of social control of polymorphism in termites, one of the most astounding of all forms of social regulation in animals Termites may have up to seven different castes in most of which each sex is equally represented The newly hatched insect is capable of developing into any of the castes by a series of moults Some forms may also have regressive moults leading back to an earlier stage in the series Caste determination mainly acts by directing moults in the required direction, but the workers may also reduce a caste to its correct proportions by selective cannibalism The direction of moults is influenced by active substances or pheromones which are exchanged among members of the colony This is most clearly established in the inhibition of the reproductive caste by members of the same caste already present Luscher has shown by fixing a queen in a screen so that her head is in one colony and her abdomen in another, and then varnishing over parts of her body, that the active substance comes from the anus Complete inhibition, however, requires the presence of a male as well as a female reproductive, so that there seem to be two substances Another one is probably involved in the inhibition of the soldier caste There are also stimulating substances, more males, for example, being produced in a colony with a queen but no king than in one without either Termites are only responsive to such influences for part of the time intervening between each moult The substances probably act through an effect on the ductless glands of the insect There may be as many as eight different pheromones, but none is as yet chemically determined

Dr. A D Lees then described the clonal polymorphism of aphids, especially in *Megoura viciae* Aphids may reproduce viviparously and parthenogenetically or be fertilized and lay eggs They may be winged or apterous and there is more than one kind of wingless female The full development of some of the morphal characters may appear gradually during several successive generations Other morphs (for example, sexual-parthenogenetic) are strict alternatives Controlling mechanisms are almost all environmental, acting through the endocrine system Aphid reproduction is extremely precocious so that an embryo will already have ovulated at its deposition and it is thus necessary to determine which of the three generations is being affected Males can be suppressed by suitable temperatures or in some species photoperiod but are otherwise produced in a characteristic percentage Egg-laying females are produced at photoperiods of less than 15 hr and temperatures of about 15° C Winged forms arise as a result of crowding and this is not an indirect effect acting through the host-plant There is also an 'interval-timer' which does not allow sexual forms to be produced for some time (50–60 days at 15° C) By selecting the first and last members of each generation to start separate lines, it can be shown that the interval is a matter of days and not of generations

Continuous polymorphism in locusts described by Dr. J. S Kennedy is different from most of the other examples in that the morphological differences are relatively slight and intermediates are often commoner than the extremes Yet not only the morphology but also almost every aspect of behaviour and physiology are somehow affected Phase transformation is largely controlled by population-density, which may act directly or on the previous generation. Genetic make-up, temperature and other factors may also have some importance The solitary phase may be regarded as more juvenile than the gregarious one, and recent experiments have shown that the prothoracic gland which normally determines a juvenile morphology persists throughout life in the *solitaria* although disappearing early in the adult *gregaria* Dr Kennedy suggested that *solitaria* is adapted to a 'soft' habitat where food is available without much movement *Gregaria* is suited to a 'hard' habitat which can be exploited only by the continuous movement which is typical of the phase. The polymorphism as a whole allows the species to exploit a much wider habitat than one phase could alone

Dr J H Sang, speaking on the environmental control of mutant expression, dealt with a developmental problem In the course of growth a gene may produce a graded response in an enzyme which nevertheless has a discontinuous effect on adult development Thus the gene 'antennaless' in *Drosophila* determines 0, 1 and 2 antennæ but nearly always perfect structures This is because the action of the gene occurs during a very short but well-defined period, namely, between the seventieth and eightieth hours of larval growth. This is shown by transferring larvæ of various ages to a different culture medium, for the effect of the gene can largely be nullified by suitable food. Such examples suggest how polymorphism might be determined by either a genetic or an environmental switch mechanism, in which influences at the right state of growth may produce large and discontinuous changes in the adult

Prof V B Wigglesworth, in a tentative synthesis, drew analogies between the polymorphism of cells in different parts of the body, the polymorphic aspect of insect metamorphosis and the phenomena which the other speakers had discussed He showed that there seemed to be a complete transition from variation in which genetic determination was almost absolute to that in which external environmental factors decided between several alternatives

The animated discussion which followed the invited contributions did not bring forward many really new points but was chiefly concerned with the relative importance of genetic and non-genetic factors in particular examples Terminology was also discussed, and some speakers were unwilling to speak of polymorphism unless the variations were clearly discontinuous The suggestion, however, was made that the best distinction was between situations in which there is selection for increased variability as opposed to the more normal case where deviations are discouraged O W RICHARDS

MOLECULAR BIOLOGY AND POPULATION STRUCTURE

A SYMPOSIUM on "Molecular Biology and Population Structure" was held at Norwich on the afternoon of September 4 at a joint session of Sections D (Zoology) and K (Botany) of the British Association for the Advancement of Science The aim of the symposium was not so much to present new discoveries as to demonstrate to the audience the interrelations of recent discoveries in these fields, and to discuss some of their implications

The symposium was opened by Dr T. Alderson (British Empire Cancer Campaign), who described what we know of the structure of deoxyribonucleic acid (DNA) and brought out some of the evidence that genetic differences as we observe them are the resultant effects of differences of DNA molecules Dr J A Pateman (University of Cambridge) followed with a discussion of the evidence that gene differences have their effects by influencing the structure of protein molecules, though in discussing, at the end of his review, the recently discovered class of genes that appear to have the capacity of "turning on and off" whole metabolic sequences, he pointed out that there is evidence that these do not operate by producing proteins These new regulator genes may well prove of major importance for our understanding of differentiation Prof H. Gruneberg (University College, London) then made the connexion between enzymes and more conventional characters by describing some beautiful examples, from his work with mice, which showed how the little invisible differences in chemical structure may be magnified during embryological development into the larger more obvious differences with which the study of genetics began

At this point the symposium turned to what at first sight was another topic altogether, when Prof J. M Thoday (University of Cambridge) described how a variety of genes may be maintained in a population if that population were exposed to a variety of demands Dr P M Sheppard (University of Liverpool) then went on to discuss some of the evidence, illustrated from his work on butterflies, that the variety of genetic types in a population are not only directly adapted to the variety of conditions which the members of the population can exploit to promote survival, but must also be adapted to one another The population is an integrated unit, and over the generations the genetic contents of different components of the population are judged not only by their individual success but also by the degree to which they co-operate with one another when brought together in sexual reproduction The chromosomes of a population have not only to have genetic properties that are to be understood in terms of the needs of individuals but also other genetic properties only to be understood in terms of the population as a whole Among other things the chromosomes of different individuals have to be co-adapted to one another if the population is to function successfully over the generations

Dr C. A Clarke (Royal Infirmary, Liverpool) followed Dr Sheppard with a little of the evidence that all these principles apply to man just as much as to *Drosophila*, or butterflies

Prof J M Thoday gave the final paper He pointed out that the two most striking discoveries of modern genetics had been brought together in this symposium

The first discovery concerns the molecular nature of the genetic material It has, of course, long been supposed that genes are molecules of some sort or another, but the precise knowledge of their molecular nature we are now acquiring is one of the most spectacular achievements of biology

The second discovery is of a different kind and was less expected. Both mathematical studies concerning the way genes might be supposed to behave in populations, and the biochemical concept that genetic variation means variation of the enzyme content of individuals, led us to expect that a population should be rather uniform genetically, each individual having much the same genetic make-up as other individuals Further, this is the expectation we seem instinctively to tend towards in our attitude to our own populations, in our concept that the people we know and with whom we have a sense of belonging are essentially like ourselves

It was this belief in the relative genetic uniformity of populations that gave such interest to the pioneer investigation of cases of obviously polymorphic populations which formed evident and striking exceptions to this expectation. Polymorphic populations are populations in which two alternative genes are both frequent, whereas simple theory would lead us to expect one to oust the other so that the population would tend to uniformity One case of polymorphism, sickle-cell anæmia in man, mentioned in a number of the papers, provides an example where population genetics and molecular biology tie up closely together

Study of such polymorphisms not only led to their explanation but also helped us to make the discovery that cases of polymorphism such as Dr Sheppard discussed are far from being exceptional They are only the striking and obvious examples of what is a normal phenomenon For the expectation of genetic uniformity is not in the least borne out by fact in any well-studied population The facts are quite contrary. Populations of sexually reproduced species consist of a wide variety of genetically different individuals and the genetic differences are in fact usually greater than the differences that we can see So great is this genetic variety that we may go so far as to say that no two individuals (apart from identical twins) are genetically alike This applies not only to flies and butterflies but also to man, in fact the evidence that it is true for man is probably more complete than it is for any other organism Each of us is genetically different from all the others. This genetic or biochemical individuality is one of the major facts of life

Along with the discovery of this genetic, or biochemical, individuality has come explanation of it at least in general terms The basic explanations are two

The first invokes the fact that we live, and all our ancestors have lived, in an environment that changes slowly with time It changes as the climate changes, and it changes as other organisms change We, that is the species to which we belong, have therefore inherited from the ancestral populations from which we have descended the means to change as the environment changes, a means that permits change in directions the necessity of which could not be foreseen. Sexual reproduction which permits the generation of a variety of genetically different individuals, and death, which permits the elimination of those individuals less-well adapted or no longer adapted to the environment, provide that means of change Sexual reproduction, however, only permits the generation of a variety of genetically new individuals, it does not ensure it unless there already is a variety of individuals. Hence, in the long term, natural selection in a changing environment must result in the continued survival only of populations that contain and always contained enough genetic variety to be able to produce the new variants that new environments require.

The second explanation is one which has developed more recently It is not an alternative to but supplements the first This explanation invokes the fact that the environment in which a population lives is not uniform in space Different parts of the population meet different environments Hence we must expect that, in different parts of a population, genetically different kinds will tend to be the fitter, so that variation of the environment in space must lead to the selection of genetical variety within the population The results of the laboratory work done to test this view lead to the conclusion that this is a most powerful factor, selection for variety is astonishingly successful

We therefore begin to have an understanding of the function in life of this surprising biochemical variety that has been found in natural populations It is the basis of the means of maintaining the population successfully in conditions that vary with space and change with time, and it is the prerequisite of innovation

Prof Thoday went on to discuss at some length some of the implications of this knowledge as it applied to man, pointing out that, though we know little of the genetics of normal variation in man and need much research on it, we do know enough to be sure that within the range of what are called normal humans there is every sort of variety to be found Each of us is different in molecular constituents that affect all classes of characteristics, whether physical or mental How much vitamin we need to remain healthy, what our normal blood pressure is, what our taste preferences may be, how sociable we are, how quick in the uptake, how liable to fall to temptation, most things will be affected by our innate molecular constitution as well as by our upbringing

This is not to deny the plastic adaptability of *Homo sapiens*. Plasticity of the individual is one of the striking properties of man, and environment in the general sense, which includes other people and upbringing in particular, can have great effects on the characteristics of human individuals Nevertheless, we may be sure that the effect that a particular environment and upbringing will have on one man will differ from its effects on other men Their genetic differences will ensure that this is so

Now this is a consequence of our knowledge to which we shall find it difficult to adjust ourselves, but it has a bearing on almost every important human topic we discuss, because most important problems in some way or other involve the question of the justice of inequality in human society Contemporarily, questions of equality in educational opportunity and the justice of giving the more promising, in so far as we can assess them, better opportunities in grammar schools, provide an excellent example of a topic in which the facts of genetic variety are seldom dispassionately considered But we must, some time, face the question of the relation between such topics and our knowledge that most, if not all, differences between people, and between classes of people, are in part genetic as well as being in the remaining part environmental in causation. Our sense of justice goes against accepting the fact that some people are biologically better endowed than others from the point of view of their capacity to profit from education and their capacity to return to society a profit on the cost of their education But it is a fact nevertheless life is not just in this sense It is time that we realized that all men are of equal value just because all men are different Some are better for some purposes, some for others and their variety, which is the basis of the richness of life, is at their initiation there, a cardinal fact of life, arising from the uniqueness of the molecules that form their basic genetic endowment Society should be organized to profit from that individuality, not suppress it, however inconvenient it may be to bureaucrats and mass-production marketers Further, if we could but accustom ourselves to the fact of human variety we might less often fall into the errors to which the type concept leads in our attitude to the differences between classes and between races The hidden genetic variety within a group is much more striking than are the evident differences that distinguish groups within a species

J M. THODAY

BIOLOGY IN BRITAIN

PROGRESS within any major branch of science is inevitably uneven Thus, there has been in the post-War period very rapid scientific advance in certain aspects of biological science particularly amenable to study by modern chemistry and physics Unaware of the outstanding problems of biological science this has led some authors to advance such judgments as "modern science has all but wiped out the borderline between life and non-life"[1] Such over-enthusiastic assessments in their extreme form amount, as Commoner[2] has pointed out, almost to a declaration that biology as a separate science is no longer needed Perhaps more dangerous is the reaction which now calls for a unifying of biological science by amalgamating existing disciplines in a way which, in practice, effects their contraction or elimination in favour of new, fashionable but frequently very restricted 'subjects' Further, the call for such changes is often prefaced by the contention that established biology teachers are out of touch with modern biology. Dr Wyatt's recent article[3] is tinged with this approach

His statement "the classical biology of pre-War years has changed little" is placed in a context which clearly implies its decreasing relevance to the main stream of biological thought rather than emphasizing that its slower development arises both from the resistance of many of its major problems to rapid solution and a lack of research resources His contention that the American biology graduate is better equipped to teach other subjects (a rather doubtful role), to read the journals and to do and to direct research is too sweeping, despite the excellence and breadth of the biological education offered in some American universities His contention that British students may learn more about modern biology from *The New Scientist*, the Penguin Science Survey and television than they gain from the isolated subject studied at a university at best displays lack of knowledge of many existing degree courses and of the separate and complementary role of important media of general scientific education

Dr Wyatt's solutions for the difficult problems facing many of us who are concerned with training biologists are too easy For example, he finds the course for the diploma of technology in applied biology far, I imagine, beyond the hopes or intentions of its originators, to be more suited for academic biology and research than are the courses (and this presumably means any and all courses) offered at the universities

It should be emphasized that there is ample evidence that, in Britain and other countries, teachers of biology are at present deeply involved in a re-assessment of their teaching programmes For example, in March of this year, at a meeting attended by almost all the professors of botany in British universities, very careful consideration was given to such problems as the sixth-form courses most appropriate for those intending to become biologists (emphasizing the need for basic training in the physical sciences and in mathematics), the rapidly changing character of university courses and the need for improved facilities, particularly for teaching in biochemistry, physiology and genetics, the influence of present Government statements on the recruitment to biology of first-class students and the financing of fundamental biological research Further, new science buildings are being used to bring under one roof, and hence into close contact, groups of related departments, as exemplified by the new Biology Building at Birmingham and the Natural Sciences Building in my own University College Biologists who, in their undergraduate courses and postgraduate work, have specialized in biochemistry, biophysics, microbiology and genetics are increasingly being appointed to existing departments of botany and zoology

Dr Wyatt rightly raises the question of the establishment of departments of biology as against continuing along a pathway of increasing fragmentation This is in line with the recent memorandum of a Royal Society Committee consisting of fifteen of its Fellows, representative of all the major fields of biology Insulated, introspective departments, if entrusted with the teaching of any branch of biology, will inevitably tend to deny to their students the value of the collaborative activity which has so evidently been effective in making many recent advances in our science Nevertheless, there are dangers and difficulties in fully and quickly effecting the proposed re-organization One of the difficulties hampering effective biology teaching is only now being eased by the present rapid expansion of higher education. Only recently in many institutions has it become possible to build up towards a teaching staff in biology whose training and research interests are sufficiently varied to give the desired range of related courses One of the dangers is revealed in Dr Wyatt's approach when, specifically mentioning as staff members, an ecologist, a physiologist, a biochemist, a microbial geneticist, a plant pathologist and perhaps an embryologist, he contends that courses in zoology, botany, biochemistry and microbiology, as well as in chemistry, can be made available by a biology department The danger here, in its extreme form, is that 'molecular biology', instead of being visualized as a major and active field of discovery, is put forward as already synonymous with the whole of biology This danger is, in fact, at present a matter of deep concern to many distinguished American biologists The Royal Society Committee, taking a broader view of the scope of biology, clearly recognized the need for some 6–8 professorial appointments together with a substantial number of non-professorial staff in order to establish a really effective unit for teaching and research in the biological sciences

[2] Commoner, B, *Science*, **133**, 1745 (1961)

[3] Wyatt, H V, *Nature*, **191**, 960 (1961)

If biologists wish to avoid "molecular biology", "in its extreme form", then we must devise courses that will attract potential physical scientists Can we be complacent when biochemists are becoming more divorced from biology and when more of the better students study neither botany nor zoology ? While I argued for experimental biology, at the same time I emphasized the greater need for studying live animals and plants not only in field studies but also in the laboratory. It is not that our established biology lecturers are out of touch, but that our organization, syllabuses and examinations are. Because I believe that biology is relevant, I wish to see more physical scientists study it

The memoranda of the Royal Society and of the professors of botany are both in private circulation; other biologists would be glad to read them

CONQUEST OF HUNGER

A SYMPOSIUM on food supply and population was an important feature at the meeting of the British Association for the Advancement of Science in 1960 in Cardiff Papers bearing on this theme were delivered by a number of leading authorities, followed by discussions (see *Nature*, 188, 9, 1960) The papers have now been published by the British Association in a booklet called *Hunger Can it be Averted ?* edited by Sir John Russell and Dr Norman C Wright* The booklet, with a preface by Sir John, contains the following articles "The Current Food Supply Situation and Current Trends", by Dr Norman C Wright, "Population Prospects and their Implications", by Prof D V Glass, "Economic Conditions for Greater Output", by Prof W A Lewis, "Land Use and Food Production", by Prof L Dudley Stamp, "Industrial and Technological Needs", by Lord Fleck, "What Limits Food Production ?", by Prof H D Kay, "Some Conclusions", by Prof P M S Blackett There is an appendix, with seventeen figures, entitled "Vast Population Increases Intensify the Battle Against Hunger"

The booklet presents the main facts about food supply and population lucidly and without emotional bias, as might be expected from the high status of the contributors What are these facts ? If world population continues to increase at the present rate it will double itself by A D 2000, and nothing likely to happen within the next few decades will reduce this rate of growth, due largely to 'death control', which will become steadily more effective In fact, the rate of increase will probably accelerate as the expectation of life rises in the developing countries and the saving of child life—the field in which modern medicine and public health have achieved their most striking successes—produces a population structure particularly favourable to high fertility.

At present large numbers of people in the world are under-fed and badly fed, so that existing food supplies are inadequate To feed the much larger population of 1980–2000, much more food than is now being produced will be needed. The quantities required, at given levels of consumption, can be roughly estimated Potentially, they can be made available by distributing surpluses, bringing new land under cultivation and increasing yields For economic and political reasons the contribution of surpluses is unlikely to be important There are wide areas, at present unproductive, which can be brought under cultivation at great effort and cost, but the most promising possibilities lie in increasing yields from land already under cultivation Sufficient technical knowledge already exists to increase yields enormously in most parts of the world, and this knowledge is being extended year by year There is plenty of dramatic evidence showing what can be achieved, for example, by using more fertilizers It is a familiar fact that yields of rice in Japan are 3–4 times greater than in India, a difference due to the large amounts of inorganic fertilizers used in Japan, combined with improved seed varieties, controlled irrigation and efficient cultural practices The crux of the matter is whether solutions can be found to the economic, political, social, educational and administrative problems which prevent technical knowledge from being effectively applied As Prof Blackett puts it "to raise the low level of much of the indigenous agriculture and to bring under cultivation more of the abundant cultivable land requires a massive educational and social advance combined with heavy capital investment in communications, housing, schools, agricultural implements, fertilizers, irrigation and drainage and, as Prof Kay has pointed out, barbed wire". The key lies in the "massive educational and social advance"

Departments of agriculture in many countries are at present under-staffed and often ineffective, and great efforts are needed to establish extension services to bring modern techniques to cultivators Food crops for local consumption usually receive less attention from agricultural departments than cash crops Technical assistance to developing countries in fields concerned with food production should be given on a much greater scale These and numerous other facts with an important bearing on the situation are discussed by the contributors.

While the booklet deals adequately with population trends and prospects, it does not go deeply into the basic issue of population control. It is primarily concerned with practical and inescapable problems of food supply and population which mankind must face in the near future. On these it says nearly all that can be said and much that has been said before. The picture is indeed clear enough. In the preface,

* *Hunger Can It Be Averted ?* Edited by Sir E John Russell and Dr Norman C. Wright Pp v+80 (London British Association for the Advancement of Science, 1961) 5*s*

Sir John Russell comments "the broad conclusion was that hunger need not be feared for at least the next forty years and this result could be achieved on present knowledge if only it were properly applied

These optimistic conclusions from such an authoritative group come as a great relief after the pessimistic gloom that has long surrounded the subject" The booklet may not produce this impression on all its readers, who should be many

W R AYKROYD

PLANT PHENOLICS GROUP OF NORTH AMERICA

THE recent increase of interest in the biology and chemistry of the phenolic constituents of plants becomes immediately apparent on inspection of the lists of contents of many of the world's biological and chemical publications However, workers in the various fields embraced by an interest in the plant phenolics are widely scattered throughout departments of botany, biology, biochemistry, chemistry, microbiology, pharmacy, pharmacology and forestry, in universities, research institutes, government agencies and in industry There is consequently almost no common meeting place for people with such interests, with the result that there is little discussion and exchange of information between workers of the different disciplines

In 1956, the Plant Phenolics Group was founded in Great Britain as an informal organization with the aims of promoting "the advancement of the knowledge of phenolic and related constituents of plants in respect of their chemistry, function, biosynthesis, effect on plant and animal physiology and pathology, and the application of such knowledge in agriculture and industry". Since its founding the Plant Phenolics Group has been very successful in achieving these aims, holding two or three meetings a year The proceedings of many of these meetings have been published

At the ninth International Botanical Congress in Montreal in 1959, discussions with various biochemists and physiologists interested in plant phenolic substances led to the idea that a sister organization be formed in North America The largest problem with forming such a group on this continent, of course, results from its geographical size, which would prohibit such a group from meeting more frequently than once a year.

An organizing committee, consisting of Dr. T. A Geissman (University of California), Dr V. C Runeckles (Imperial Tobacco Co of Canada) and Dr G H N Towers (McGill University), distributed a letter to interested persons in 1960, the response to which was so enthusiastic as to encourage the committee to make plans for an inaugural meeting This was held at Colorado State University, Fort Collins, during August 31–September 1, and took the form of a symposium on the biochemistry of plant phenolic substances. The meeting was sponsored by the National Science Foundation under the direction of Mr. G Johnson of Colorado State University, and Dr Geissman The papers presented were "Recent Studies on the Structures and Bitterness of the Flavonoid Glycosides of Citrus" (Dr R. M. Horowitz, U S Department of Agriculture, Albany, California), "Biosynthesis of Plant Phenols" (Dr. S A. Brown, National Research Council, Saskatoon), "Naturally Occurring Biflavonyls" (Dr. N. Kawano, University of Nagasaki Japan), "Metabolic Fate of Phenolic Substances in Animals" (Dr A. N Booth, U S Department of Agriculture, Albany), "Role of Plant Phenolics in Disease Resistance and Immunity" (Dr I Uritani, Nagoya University, Japan), "Melanin and its Formation" (Dr. G. A Swan, University of Durham) and "Estrogenic-like Substances in Plants" (Dr E M Bickoff, U S Department of Agriculture, Albany) It is hoped that the proceedings of the symposium will be published

More than sixty delegates attended the symposium, the last session of which was devoted to founding the Plant Phenolics Group of North America The officers elected were: *president*, Dr S H Wender (University of Oklahoma), *vice-president*, Dr L Jurd (U S. Department of Agriculture, Albany), *hon secretary-treasurer*, Dr V C Runeckles

It was agreed at the first meeting that membership of the Plant Phenolics Group of North America be open to all persons interested in the Group's aims, on application to the secretary, Dr. V. C. Runeckles, P O. Box 6500, Montreal, Quebec.

V. C RUNECKLES

RESEARCH WITH TROPICAL PLANTS

THE Tropical Products Institute of the Department of Scientific and Industrial Research is continuing its work on the examination of plants from tropical territories, and a recent report outlines the scope of investigations carried out during 1960*

Any new sources of drugs could be of great economic benefit to the countries to which the plants are indigenous, and the Institute's activities follows representations from overseas governments for technical assistance in this field Already 314 plants have been tested, including specimens from North Borneo as well as samples from Kew Gardens A number of alkaloid-containing plants have been found and are being subjected to further tests The Director of the Institute reports the expansion of economic and long-term research work by the Institute to meet the needs of rapidly developing tropical countries This reflects a trend away from short-term inquiries in order to help newly established laboratories overseas with their research and development problems Even more important is the demand for qualified man-power in the territories themselves, and the Institute has helped by sending visiting scientists to 39 overseas territories and by training research workers from five different tropical countries More than 900 inquiries for advice and assistance were received from 62 countries during the year. While only 10 per cent of these inquiries required laboratory investigation, they took up about three-quarters of the Institute's advisory effort.

---

* Department of Scientific and Industrial Research *The Report of the Tropical Products Institute Committee with the Report of the Tropical Products Institute* Pp viii+40 (London H M S O, 1961) 3s net.

At the request of certain Malayan pineapple producers, the Institute is investigating the reason for differences between the flavour of Malayan pineapple juice and Hawaiian and South African juices. This may be due either to the effect of local canning process on the flavouring constituents or to varietal differences inherent in the plants. Many countries have a seasonal surplus of fruits and vegetables, and the advice of the Tropical Products Institute has been sought on methods of making better use of these supplies. Although small-scale canning of surplus fresh fruits and vegetables is not generally recommended as the quality and quantity are unlikely to be sufficient for effective processing, advice was given to Fiji and Nyasaland on how to set up a small-scale canning line; to Kenya on packing pineapple slices in plastic cases; to Singapore on making cashew apple wine; and to Aden and Tanganyika on producing tomato paste or purée.

In many parts of the tropics, surplus coconuts are made into copra by drying the kernel in the open air or in special kilns. Most copra is made by the small peasant farmer and quality control is difficult. As moisture content is a critical factor in the keeping qualities of copra, the Institute is examining the effectiveness of a simple moisture meter, which was originally developed at the Pest Infestation Laboratory for testing grain. A simple portable meter of this kind could easily be used by local farmers.

For some years the United Kingdom has been looking to the Commonwealth for new sources of naval stores (turpentine and rosin). Three hundred gallons of pine oleo-resin from Mauritius were examined at the Institute to see whether it would yield good commercial quality turpentine and rosin. The samples compared favourably with American products, and it is hoped that Mauritius will be able to improve its economy by starting a small naval stores industry based on existing plantations.

Work has also begun on an improved type of solar still and the first model is being tested in Malta. In addition, water-heating equipment using solar energy, developed at the Institute in London, is now being tested under field conditions in Malta. It comprises two fully instrumented flat-plate water heaters for research purposes as well as domestic flat-plate heaters for the roofs of private houses and blocks of flats.

FORMATION OF AIR–WATER FROTHS

By J. RENNIE and W. SMITH

Warren Spring Laboratory, Department of Scientific and Industrial Research,
Stevenage, Hertfordshire

FOR the absorption of gases in liquids or for distillation on a large scale, effective contact between the two phases is obtained by dispersing gas or vapour at a high rate into a pool of liquid. Froths or foams are formed, giving a good rate of heat or mass transfer across the phase boundary. The generation of these froths is in no way dependent on surface activity: froths can be formed from pure components (Fig. 1), so that the surface tension is uniform in the pool. These froths are not stable: they collapse the instant the gas supply is removed.

One very common and simple device used for the dispersion of gas is the sieve plate. This is a flat plate, drilled with evenly spaced holes, from 1/16 to 3/8 in. in diameter, occupying 5–20 per cent of the total area of the plate. Liquid is generally run across the plate, being maintained in depths of 2–8 in. by weirs, and the gas is dispersed upwards through the holes.

In studying the performance of sieve plates, we have concentrated on froths formed by dispersing air in water. The complicating effects of mass or heat transfer between the phases, and the resulting non-uniform distribution of physical properties in the pool, have thereby been avoided. Preliminary work has been mainly concerned with devising techniques for measuring accurately the surface area and density of the dispersions[1]. It has been found that two kinds of dispersion are obtained, depending on gas-rate; relatively low gas-rates produce a stable, immobile foam of large bubbles, and high gas-rates produce an actively moving froth. It is the froth which is of practical interest, owing to the higher distillation or absorption-rates obtained.

Examination of single short-exposure photographs of froth produced over a range of conditions has shown that the important physical characteristics of the froths, such as density or surface area per unit volume, remain the same whether the plate used has one or many orifices; in particular, the size of bubbles or cells in the mass of the froth is almost uniform, and is independent of the diameter of the orifice.

As may be seen in Fig. 1, before coalescence near the surface of the pool, the bubbles in the froth are all about the same size, and smaller than the bubbles formed at the orifices. Leibson *et al.*[2], who investi-

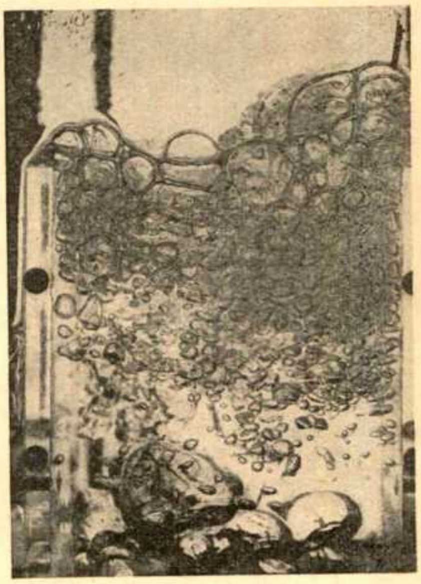

Fig. 1. Froth formed over a multiple-orifice sieve-plate in a shallow pool. Air in water

gated bubble formation at a single orifice, concluded that the small bubbles are produced by sudden shattering of the large bubbles initially formed, and this is indeed what appears to happen when the formation of the froth is followed by a slow-speed ciné camera or by eye. Helsby and Tuson[3], in a study of bubble behaviour at low gas-rates, observed the onset of coalescence between pairs of bubbles near a single orifice. To examine the process in more detail, however, we have taken ciné-photographs of the break-up of bubbles formed by single- and multiple-orifice plates at 64 frames/sec. with synchronized lighting, supplemented by high-speed photographs at 3,000 frames/sec.

Fig. 2 illustrates the behaviour of bubbles before and during disintegration; the sequence of six photographs was taken at intervals of 1/64 sec. These bubbles are formed at a single orifice of 1/8 in. diameter, in a deep pool of liquid. In frame 1 a bubble has been formed and became detached from the orifice. A second bubble is shown penetrating the first bubble, forming a neck of gas connecting it to the orifice. When the 'neck' is detached from the orifice, it may remain attached to the main bubble but separated by a film of liquid, or it may be an integral part of the main bubble. Sometimes no distinct neck is formed, but a second, smaller bubble follows the first in quick succession. In nearly all cases the neck or the second bubble overtakes the main bubble and, being usually of smaller diameter, penetrates it. Frames 2, 3 and 4 show the increasing agitation of the combined bubble as it begins to rise through the liquid. In some photographs filaments and films of liquid from the penetrating bubble can be seen within the penetrated bubble. Frames 5 and 6 show the cells of the combined bubble beginning to move apart and form separate bubbles. The further progress of the break-up can be seen by following the upper group of bubbles. On the rare occasions when a bubble is released without being penetrated by a neck or a second bubble, it remains whole until the bulk of the froth at a higher level is reached.

With slight variations (for example, at very high gas-rates more than two bubbles may interpenetrate) this mechanism of disintegration operates under all conditions which give frothing in the air–water system; the eventual size of bubble or cell of froth is almost constant. The effect of changing the interfacial tension by using other gases and liquids, and the condition where the interfacial tension depends on the life of the bubble, as when mass transfer is taking place, are now being examined.

EFFECT OF COPPER ON PRODUCTS OF ORCINOL OXIDATION

By Dr. T. F. SLATER

Department of Chemical Pathology, University College Hospital Medical School, W.C.1

THE addition of alkali (final normality approx. 0·01) to a solution of orcinol containing small amounts of copper (approx. 10^{-6} *M*) leads to the rapid production of a red-brown colour. Colours so formed in sodium hydroxide or in ammonium hydroxide are very similar providing the reaction time is short (about 1 hr.). If the alkaline orcinol reaction is allowed to proceed for a much longer time (say, several days) a marked difference between the spectra in sodium hydroxide and ammonium hydroxide becomes apparent due to the formation of the dye orcein in ammoniacal orcinol. Orcein is a

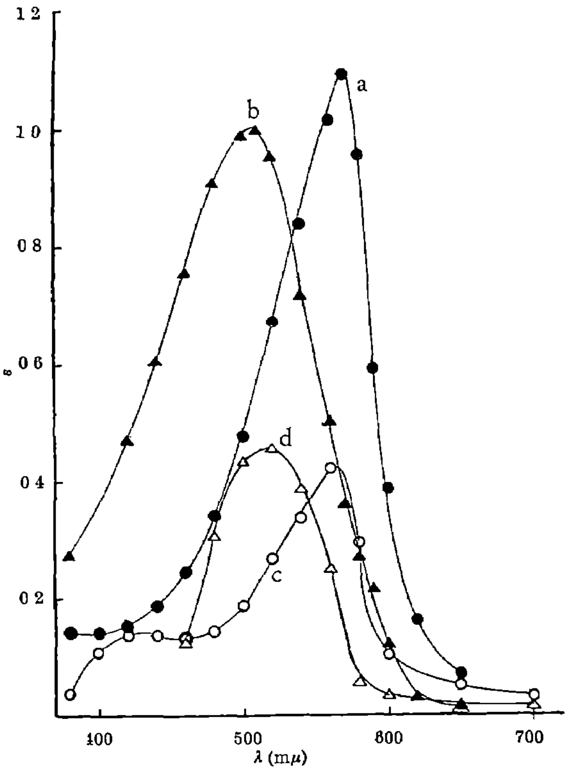

Fig 1 Absorption spectra obtained using a commercial sample of orcein *a*, in 0 1 *N* alkali , *b*, in 0 1 *N* acid , *c*, and *d*, are the alkaline and acid difference spectra for the oxidation of orcinol in the presence and absence of copper ions calculated as follows two flasks containing ammoniacal orcinol were incubated for 4 days at room temperature , one flask, *A*, contained in addition 1 ml 1 per cent sodium diethyldithiocarbamate and the other flask, *B*, contained 2 μgm copper ions After 4 days the absorption spectra of both solutions were determined and the alkaline difference spectra calculated by subtracting spectrum *B from A* Both solutions were then acidified to approx 1 *N* with HCl and the spectra again measured The acid difference spectrum was calculated by subtracting spectrum *B* from *A*

mixture of related products which can be separated by paper chromatography[1] A commercial sample of orcein obtained from British Drug Houses, Ltd , gave absorption maxima in acid and alkali at 510 and 570 mμ respectively (Fig 1)

An unexpected feature of these results was that copper ions inhibited the formation of orcein , this is illustrated in Fig 1 It can be seen that the acid and alkaline peaks formed in the virtual absence of copper ions are identical with the results found with a commercial sample of orcein It would thus appear that the complex reactions leading to the formation of the orcein dyes are inhibited by traces of copper present in the reaction mixture

The reaction between orcinol, alkali and small amount of copper with short times of incubation can be used as a quantitative method for determining low concentrations of copper Lambert[2] has published an assay method for copper based on the catalysis of resorcinol oxidation, but confined himself to assays in pure solutions and did not investigate the applicability of the method to biological samples where trace metal analysis is often required The applicability of the copper catalysis of phenol oxidation as a method for copper analysis in biological samples has therefore been investigated Since this work was started before seeing the report of Lambert[2], it is concerned solely with the oxidation of orcinol Some of the early work on this investigation was done using borate and phosphate buffers but these were later replaced by the more satisfactory pyrophosphate buffer suggested by Lambert[2]

The assay system used was to incubate 2 ml 1 per cent orcinol, 5 ml pyrophosphate buffer (0 1 *M*, *p*H 12), copper solution (0–1 0 μgm) and water to give a final incubation volume of 25 ml at 30° C for 10–30 min with shaking at 120 shakes/min Lambert proposed stopping the reaction by acidification, but this greatly decreases the extinction value and a more convenient procedure was found to be the addition of a strong copper chelator (versene) at the end of the incubation The addition of 1 ml 0 1 *M* versene *p*H 7 4 to the reaction mixture slows the reaction to negligible proportions Colour development increases with *p*H as reported by Lambert for resorcinol oxidation Under these conditions the colour increases linearly with the incubation time and linearly with the amount of copper added (respective limits studied, 1 hr and 2 μgm copper) After correction for blank colour-formation in the absence of added copper, a concentration of 1 8 × 10^{-7} *M* copper in the incubation mixture gave an extinction at 460 mμ of 0 1 (path length, 1 cm) after a 20 min incubation

The effects of metal ions commonly occurring in biological extracts was investigated to see the extent of interference in the copper-catalysed orcinol oxidation The following metal ions had no influence on the reaction when present in large final concentrations (at least 40-fold excess over copper) sodium, potassium, zinc, calcium, magnesium, aluminium and ferrous ions Cobaltous and manganous ions stimulated the orcinol oxidation in a similar manner to copper ions , ferric ions and chromic ions inhibited the reaction Comparative effects of these metal ions are shown in Fig 2 The effects of several of the above metal ions on the oxidation of alkaline orcinol are different from their effects on resorcinol oxidation[2,3] It is apparent from the results in Fig 2 that unless the biological extracts are abnormally rich in manganese or ferric ions compared with copper, the orcinol colour will be largely the result of copper-induced oxidation and, as such, will reflect the copper content of the extracts In general, the manganese content of biological extracts is much less than the copper content[4], but ferric ion inhibition is possible, particularly if appreciable blood is present As was to be expected, the copper-orcinol reaction

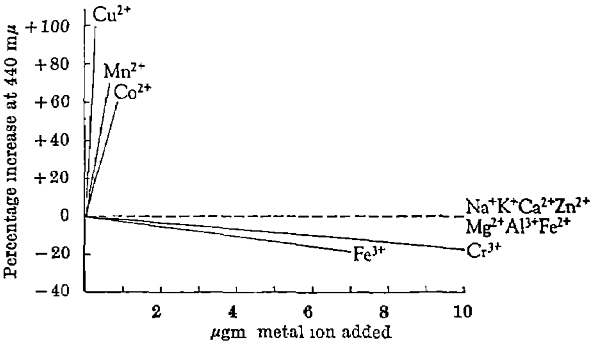

Fig 2 Effect of various metal ions on the alkaline oxidation of orcinol The ordinate expresses the percentage increase in colour (at 440 mμ) produced by the addition of metal ions compared with the colour produced in the absence of added metal, the abscissa is the amount of metal ion added in μgm Other conditions as in the text The results are representative of various incubation times from 10 min to 3 hr but are suitable for comparisons, that is, weight for weight, copper is approx three times as effective as manganese and about six times as effective as cobalt

was inhibited by traces of protein or amino-acids which bind the copper in an unreactive form Reducing and oxidizing reagents (for example, vitamin C and hydrogen peroxide) also interfere Thus if copper estimations by either the copper-orcinol or resorcinol procedures are to be carried out on biological samples, the tissue must be ashed prior to copper estimation With certain high protein/high fat samples (milk, for example) the copper orcinol procedure becomes unsuited for the estimation of low contents of copper due to the high blank values consequent on ashing. It would appear from the foregoing results and from previous work on resorcinol[2] [3] that the catalytic action of copper on phenol oxidation can be used for estimating copper in biological samples providing that the ashing procedure does not require large amounts of digestion material. In other words, the use of the method would seem to lie with samples relatively enriched in copper compared to protein/fat

Much of this work was done during the tenure of a Beit Memorial fellowship held at University College, London I am grateful to Prof. C Rimington and Dr A L Greenbaum for helpful comments.

PARTICIPATION OF IMIDAZOLE IN INTRAMOLECULAR HYDROGEN BONDING

By Prof. A. LUKTON
Brooklyn College, Brooklyn, New York

IT is generally believed that an understanding of proximity effects of neighbouring groups functioning in concerted action on an enzyme surface will lead to an explanation of the great disparity between the rates of catalysis of enzymes and of their model systems[1] Precise determination of the particular role of groups such as imidazole in enzyme catalysis thus requires that its intramolecular structural relationships be established. In this article, evidence for intramolecular hydrogen bonding involving the imidazole ring is presented

The assignment of the imidazole infra-red absorption bands were made by Otting[2] and include strong bands at 2,600–3,200 cm $^{-1}$ and at 3,475 cm.$^{-1}$. He demonstrated that the strong NH (unbonded) absorption at 3,475 cm $^{-1}$ decreased in intensity but not in frequency with increasing concentration in chloroform solution At the same time the hydrogen bonded NH bands in the region 2,600–3,200 cm $^{-1}$ increased in intensity, indicating an increase in intermolecular hydrogen bonding Recently, Anderson *et al* [3] established the relationship between the absorption intensity change and the length of the linear imidazole oligomers as effected by the imidazole concentration in carbon tetrachloride solution. Such absorption changes should be useful in determining the existence of intramolecular hydrogen bonding in compounds which contain the imidazole ring In such a structure no imidazole absorption should occur in the 2,600–3,200 cm $^{-1}$ region since imidazole participation in intramolecular hydrogen bonding would preclude the possibility of its participation in intermolecular bonding in dilute, non-hydrogen bonding solvents

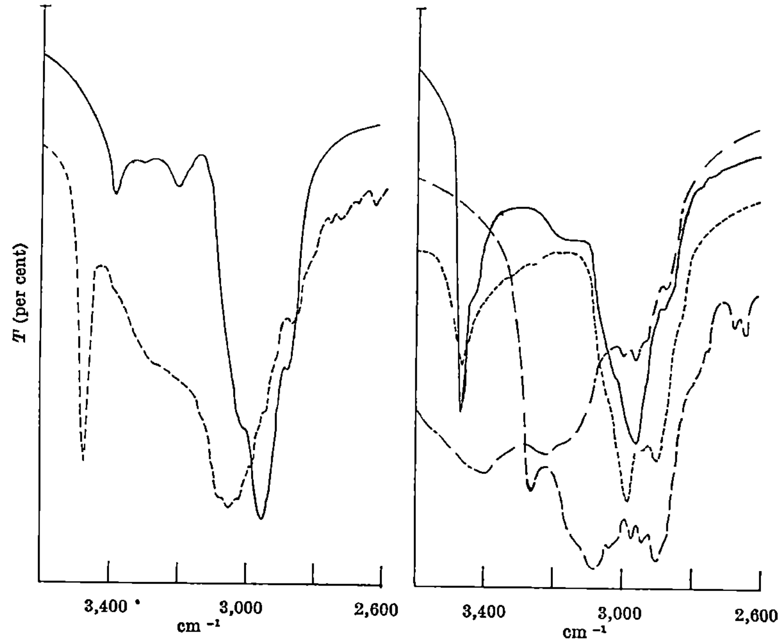

Fig 1 The infra-red absorption spectra of left, 1,4-methylhistamine in $CHCl_3$ (——), imidazole in $CHCl_3$ (– – –), right, acetylhistamine in $CHCl_3$ (– – –), acetylhistamine in KBr (— — —), methyl dihydrourocanate in $CHCl_3$ (——), methyl dihydrourocanate in KBr (— - —)

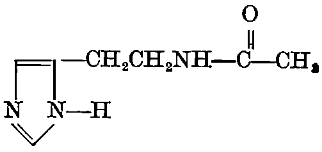
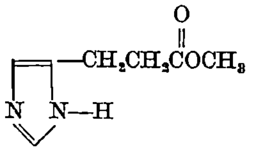
Acetyl histamine (I) and methyl dihydrourocanate (II) were studied to examine this premise



(I)



(II)

In (I) intramolecular hydrogen bonding could involve the hydrogen linked to the ring pyrrole nitrogen and the carbonyl oxygen of the amide

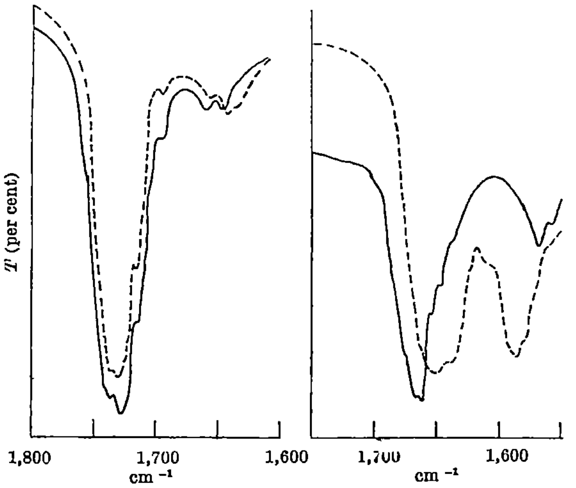


Fig 2 The infra-red absorption spectra of left, methyl dihydrourocanate in CHCl$_3$ (——), methyl dihydrourocanate in KBr (- - -), right, acetylhistamine in CHCl$_3$ (——), acetylhistamine KBr (- - -)

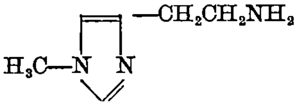
linkage ; or, the ring pyridine nitrogen and the imino hydrogen of the amide group Hydrogen bonding in (II) could result only in the bonding of the hydrogen of the pyrrole nitrogen and the carbonyl of the ester group

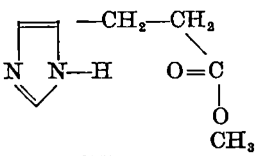
The infra-red spectra of acetyl histamine, methyl dihydrourocanate, imidazole and 1,4-methylhistamine (1-methyl-4-(β-amino-ethyl)-imidazole) in the region 2,600–3,600 cm $^{-1}$ and 1,600–1,800 cm $^{-1}$ are given in Figs 1 and 2 The 2,900–3,100 cm. $^{-1}$ region of the methyl dihydrourocanate and acetyl histamine spectra is complicated by the coincident absorption of CH, CH$_2$ and CH$_3$ The contribution of this absorption, however, was determined in the absence of imidazole NH (bonded) absorption by examining the spectrum of 1,4 methylhistamine, structure III, in chloroform solution



(III)

As shown in Fig 1, there is a strong absorption band at 2,967 cm $^{-1}$, (CH$_3$), a weak band at 2,878 cm $^{-1}$ and a shoulder at 3,007 cm $^{-1}$ The two weak absorption bands at 3,373 and 3,310 cm. $^{-1}$ are due to the NH vibration of the NH$_2$ group[4]

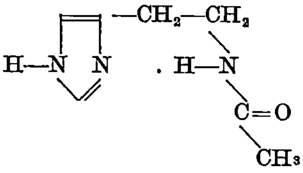
Examination of the methyl dihydrourocanate spectrum in chloroform solution reveals a spectrum similar to that of 1,4 methylhistamine with a strong band at 2,957 cm $^{-1}$ and a weaker band at 2,878 cm $^{-1}$ Furthermore, it is unlike the imidazole spectrum in chloroform solution since the strong imidazole band at 3,048 cm $^{-1}$ is completely absent and leads to the postulate that intermolecular hydrogen bonding does not occur due to the existence of the internally bonded structure (IV).



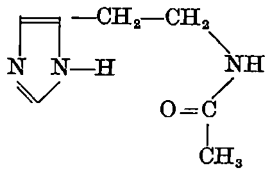
(IV)

The behaviour of the absorption band of the ester carbonyl stretching vibration in solution and in the solid state lends support for this structure Compounds such as *N*-methylacetamide in the solid state in which intermolecular hydrogen bonding occurs, absorb at a lower frequency (C=O bonded, 1,655 cm $^{-1}$) than in their dilute solutions (C=O unbonded, 1,695 cm $^{-1}$)[5,6]. However, methyldihydrourocanate absorbs at 1,730 cm. $^{-1}$ in dilute and concentrated chloroform solutions and in the solid state, Fig 2. The expected frequency shift did not occur since the hydrogen bond in this compound, whether inter- or intra-molecular, involves the same atoms That intermolecular hydrogen bonding occurs in the solid state between NH (imidazole) and C=O (ester) is indicated in its spectrum in Fig 1 Here, broad absorption bands exist at 3,390 and 3,216 cm $^{-1}$ This is characteristic of intermolecular bonded hydrogen in amides, although the amide bonds are at 3,300, 3,275 and 3,070 cm $^{-1}$ (ref 6)

The absorption spectrum of acetylhistamine in chloroform solution is also similar to that of 1,4 methylhistamine It has a strong band at 2,986 cm $^{-1}$, a weak band at 2,900 cm $^{-1}$ and it lacks the bonded NH (imidazole) band at 3,048 cm $^{-1}$ The absence of bonded NH (imidazole) absorption in this region indicates intramolecular hydrogen bonding which could result from two possible structures (V) and (VI)

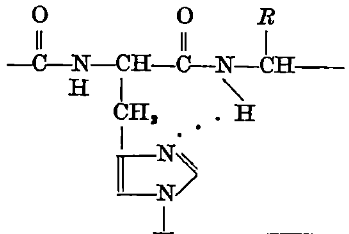


(V)

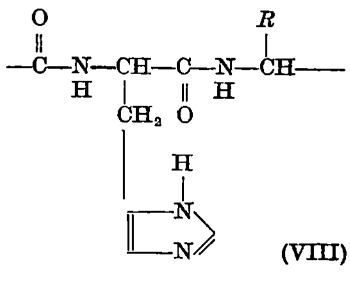


(VI)

Structure (V) is favoured because it consists of a six-membered hydrogen-bonded ring which is considerably more stable than the eight-membered ring of structure (VI)[7] Also, there is a frequency shift in the carbonyl absorption from 1,660 to 1,650 cm $^{-1}$ in going from chloroform solution to the solid state (Fig 2) As would be expected, the shift is small compared with the shift observed in completely unbonded and bonded amides



(VII)



(VIII)

The smaller frequency shift is explained on the basis of a change from intra-molecular hydrogen bonding V to intermolecular hydrogen bonding in which the NH (amide) and C=O (amide) participate. Absorption at 3,266, 3,083 and 3,035 cm.$^{-1}$ and characteristic of NH $\cdots$ O=C absorption in amides are observed in solid acetyl histamine (Fig. 1). An analogous structure to that proposed by Mizushima[8] for *N*-methylacetamide is suggested.

Several interesting consequences with respect to naturally occurring substances follow from these considerations. In so far as imidazole may participate in protein hydrogen bonding, two configurations would be possible (besides those which may involve bonding with other amino-acid residues).

Both structures contain seven-membered rings; however, structure (VIII) would be favoured. If such structures do exist in proteins, they might help provide an explanation for marked differences in reactivity of various histidine residues such as exist in ribonuclease[9].

Intramolecular hydrogen bonding in the dipeptide carnosine (β-alanyl-histidine) may exert an effect in facilitating the dissociation of the amide imino hydrogen atom during the formation of the copper carnosine chelate[10,11], also it may contribute to the base strength of the imidazole of carnosine (*pK* (*Im*) = 6.83) which is a considerably stronger base than that in histidine (*pK* (*Im*) = 6.00)[12].

I am indebted to Dr. R. W. Schayer, Merck Institute for Therapeutic Research, Rahway, New Jersey, for supplying the 1,4 methylhistamine.

This investigation was supported by a research grant from the National Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service grant No. *A*-3066.

Research on this project was conducted at Adelphi College, Garden City, N.Y.

PROPERTIES OF SOME COPPER COMPLEXES

Five-Covalent Copper(II) Complexes containing 1,10-Phenanthroline and 2,2′-Bipyridyl

THIS preliminary communication reports the preparation and properties of an extensive series of five-covalent copper(II) complexes by the reaction of *bis*(1,10-phenanthroline)copper(II) and *bis*(2,2′-bipyridyl)copper(II) perchlorates with various neutral and negatively charged ligands.

The addition of halide ions (Cl^-, Br^- and I^-) to nitrobenzene or nitromethane solutions of $[Cu(phen)_2](ClO_4)_2$ leads to the formation of variously coloured solutions (blue, green and brown respectively) containing monohalogeno-*bis*(1,10-phenanthroline)-copper(II) ions due to the reaction

$$[Cu(phen)_2]^{2+} + X^- \rightarrow [Cu(phen)_2X]^+$$

This 1 : 1 reaction has been confirmed both by conductometric titrations and spectrophotometric continuous variation studies. Also, by working in aqueous acetone solutions, a series of coloured crystalline compounds of the type $[Cu(phen)_2X]ClO_4$ (where $X = Cl^-$, Br^-, I^-, SCN^-, NO_2^-, $HCOO^-$, CH_3COO^- and $C_6H_5COO^-$) has been isolated. These compounds possess molecular conductivities in the ranges 27–29 mho and 87–90 mho at 25° in 10^{-3} *M* nitrobenzene and nitromethane solutions respectively. These values are comparable with those of other uni-univalent electrolytes in these solvents[1] and practically half those of the diperchlorate $[Cu(phen)_2](ClO_4)_2$ (Table 1). The *bis*(2,2′-bipyridyl) compound $[Cu(bipy)_2](ClO_4)_2$ also reacts readily with halide ions in the above two solvents and compounds of the type $[Cu(bipy)_2X]ClO_4$ (where $X = Cl^-$, Br^-, I^- and SCN^-) have also been isolated. These compounds possess similar conductivities to their phenanthroline analogues (see Table 1).

Table 1. MOLECULAR CONDUCTIVITIES AND MAGNETIC MOMENTS OF VARIOUS 1,10-PHENANTHROLINE AND 2,2′-BIPYRIDYL COMPLEXES OF BIVALENT COPPER

Compound	Molecular conductances (mho) in 10^{-3} *M* solutions at 25°		Magnetic moment per Cu atom in B.M.
	$C_5H_5NO_2$	CH_3NO_2	
$[Cu(phen)_2](ClO_4)_2$	43.1	176	1.94
$[Cu(phen)_3](ClO_4)_2$			1.91
$[Cu(phen)_2X]ClO_4$ ($X = Cl^-$, Br^-, I^-, SCN^-, NO_2^-, $HCOO^-$, CH_3COO^- and $C_6H_5COO^-$)	27–29	87–91	1.83–1.96
$[Cu(phen)_2X]X$ (Cl^-, Br^-, I^-, SCN^-, $HCOO^-$ and CH_3COO^-)	24–27	82–93	1.86–1.97
$[Cu(phen)_2L](ClO_4)_2$ ($L = NH_3$ and C_5H_5N)		176–199	1.84–2.00
$[Cu(bipy)_2](ClO_4)_2$	54	186	2.03
$[Cu(bipy)_3](ClO_4)_2$	44.5	181	1.93
$[Cu(bipy)_2X]ClO_4$ ($X = Cl^-$, Br^-, I^-, and SCN^-)	28–31	89–91	1.89–1.97
$[Cu(bipy)_2X]X$ ($X = Cl^-$, Br^-, I^-, and SCN^-)	11–30	79–85	1.81–1.96
$[Cu(bipy)_2NH_3](ClO_4)_2$		199	1.92
$[Cu(bipy)Cl_2]$		~1	1.96

Attempts to prepare a monocyano-derivative of the $[Cu(phen)_2]^{2+}$ ion lead to the isolation of the cyano-bridged complex

$$[(phen)_2Cu - C \equiv N - Cu(phen)_2](ClO_4)_3 \cdot H_2O$$

in which the cyanide group is linking two $[Cu(phen)_2]^{2+}$ ions.

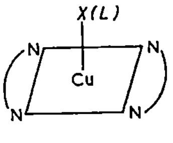
The *bis*-complexes $Cu(phen)_2X_2 \cdot nH_2O$ ($X = Cl^-$, $n = 3.5$, $X = Br^-$ and I^-, $n = 1$, $X = SCN^-$, $n = 0$, and $X = HCOO^-$ and CH_3COO^-, $n = 6$) and $Cu(bipy)_2X_2 \cdot nH_2O$ ($X = Cl^-$, $n = 6$; $X = Br^-$, $n = 2$; $X = SCN^-$ or I^-, $n = 0$) were also prepared and their properties examined. These complexes are also uni-univalent electrolytes in nitromethane solution (Table 1) and contain the $[Cu(chelate)_2X]^+$ ion. In the more weakly polar solvent nitrobenzene they undergo some re-arrangement due to the reaction

$$[Cu(chelate)_2X]^+ + X^- \rightleftharpoons [Cu(chelate)X_2] + chelate$$

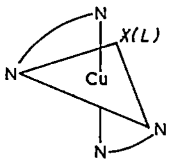
This equilibrium, which is independent of concentration, has been studied in detail by means of accurate conductivity measurements over a concentration range and will be reported later[2]. Mono-complexes of the type [Cu(bipy)X_2] (where X = Cl^-, Br^- and SCN^-) were prepared and examined during the course of this work. For example, the dichloro-complex [Cu(bipy)Cl_2], which is readily obtained by adding the ligand to excess copper(II) chloride in ethanol, is virtually a non-electrolyte in nitromethane solution (Table 1).

The reaction of neutral ligands with $[Cu(phen)_2]^{2+}$ and $[Cu(bipy)_2]^{2+}$ has also been studied and the stable mono-ammine complexes $[Cu(chelate)_2(NH_3)](ClO_4)_2$ were obtained from aqueous ammonia solutions. The *bis*(1,10-phenanthroline) complex also forms the mono-pyridine complex $[Cu(phen)_2(py)](ClO_4)_2$ as well as the aquo-derivative $[Cu(phen)_2(H_2O)](ClO_4)_2$. These compounds function as di-univalent electrolytes in nitromethane solution (see Table 1).

There is a number of possible structures for the five-covalent ions $[Cu(chelate)_2X]^+$ and $[Cu(chelate)_2L]^{2+}$ (where X is a negative ion and L is a neutral ligand). They could, for example, possess the square-pyramidal arrangement I, or the trigonal bipyramidal one represented in II.



(I)



(II)

In this regard it is of considerable interest that Barclay and Kennard (see following communication) have shown that the structure of iodo-*bis*(2,2′-bipyridyl)copper(II) iodide contains an approximately trigonal bipyramidal arrangement about the copper atom in the $[Cu(bipy)_2I]^+$ ion. This type of arrangement confers the possibility of mirror-image isomerism on the copper atom and the unit cell contains both isomers. The X-ray data reveal that the Cu – N and Cu – I distances correspond to normal covalent bond distances whereas the stereochemistry of bivalent copper is usually such that the copper atom is surrounded by four atoms at normal covalent bond distances in the plane with one or two more elongated bonds normal to the plane.

The magnetic moments of the 5-covalent complexes in the table all fall in the range 1·8–2·0 B.M. These values are similar to those of copper(II) complexes in general.

The magnetic moments of $[Cu(phen)_2Br]ClO_4$ and $[Cu(phen)_2Br]Br$ have been reported previously as being essentially independent of temperature over the range 90–300° K (ref. 3).

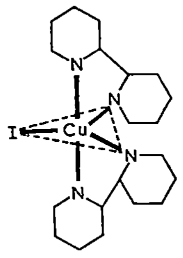
The Trigonal-Bipyramidal Configuration of the Iodo *Bis*(2-2′-Bipyridyl)Copper(II) Ion

The compounds $Cu(dipy)_2X_2$ and $Cu(phen)_2X_2$ formed between 2,2′-bipyridine or *o*-phenanthroline and copper(II) salts have been shown to have co-ordination numbers of five in non-aqueous solutions (see previous communication). The purpose of this communication is to record preliminary results of an X-ray structure determination of one of them, *bis*(2,2′-bipyridyl)copper(II) iodide.

The lustrous brown crystals are triclinic (a = 10·66 ± 0·01, b = 14·37 ± 0·01, c = 7·44 ± 0·01 Å, α = 93 ± 1°, β = 101 ± 1°, γ = 108 ± 1°). There are two molecules of composition $Cu(C_{10}H_8N_2)_2I_2$ in the unit cell (d_{meas} = 1·99, d_{calc} = 1·98 gm cm^{-3}). The centro-symmetric space group, $P\bar{1}$, was assumed.

One-thousand-four-hundred independent intensities were estimated visually from equi-inclination Weissenberg photographs taken with copper radiation. The co-ordinates of the atoms were determined from three-dimensional Patterson and Fourier syntheses. With a disagreement index (Σ| |F_{obs}| – |F_{calc}| |/ Σ|F_{obs}|) of 0·18, the estimated standard deviations of the atomic positions were I, 0·003, Cu, 0·005, N, 0·03, C, 0·05 Å. The structure is being refined further in an attempt to locate the light atoms more precisely. However, it is quite clear that the copper atom has an unusual stereochemistry.

The compound contains a positively charged iodo-*bis*(bipyridyl)copper(II) ion and a negatively charged iodide ion. The copper atom is surrounded by four nitrogen atoms (at a distance of 2·02 Å) and an iodine atom (at 2·71 Å) at the corners of a distorted trigonal bipyramid. The iodine atom and two nitrogen atoms (from different bipyridine molecules) are in the same plane as the copper atom. The other two nitrogen atoms lie on a line (passing through the copper atom) which makes an angle of about 9° with the normal to this plane. The arrangement is shown in III.



(III)

All five atoms are at normal covalent bond distances from the copper atom. The trigonal bipyramidal configuration for the copper atom differs in this respect from the usual stereochemistry of bivalent copper which involves four bonds of normal covalent lengths with a fifth, and sometimes a sixth, at a greater distance. As the iodo-*bis*(2,2′-bipyridyl)-copper(II) ion possesses neither a plane nor a centre of symmetry, the two ions in the unit cell are related to one another as optical isomers.

Terpyridylcopper(II) chloride dihydrate is isomorphous with terpyridylzinc chloride, which has a similar trigonal bipyramidal configuration about the metal atom[4].

THERMAL REACTION BETWEEN TWO LIGHT REACTIONS IN PHOTOSYNTHESIS

By Prof C P WHITTINGHAM and P. M BISHOP
Botany Department, Queen Mary College, London, E I

ALLEN and Franck[1] showed with the alga *Scenedesmus* that a single flash of less than 1 msec in duration resulted in no detectable oxygen evolution from photosynthesis If two flashes were given, separated by a suitable dark interval, a measurable yield was obtained Alternatively an increased yield was obtained when a single flash was superimposed on a continuous background of low intensity Whittingham and Brown[2] confirmed and extended these observations with the alga *Ankistrodesmus* They interpreted their results in terms of two photochemical reactions, the first of which was thought to activate an essential catalyst of photosynthesis, the second being concerned in photosynthesis directly.

More recent work has suggested the existence of two photochemical reactions in the photosynthetic process This has been postulated to explain the enhancement (or 'Emerson') effect on photosynthesis obtained with a number of algæ excited with light of two different wave-lengths[3]. Govindjee *et al* [4] showed that the enhancement effect was also observed for the photoreduction of quinone by *Chlorella* (Hill reaction) Duysens *et al* [5] showed with *Porphyridium* that light, absorbed by the phycobilins, preferentially resulted in the reduction of cytochrome *f*, whereas light at 680 mμ absorbed by chlorophyll predominantly oxidized the cytochrome Losada *et al* [6] independently suggested, on the basis of work with isolated chloroplasts, that one pigment system was concerned in the liberation of oxygen from water and the transfer of an electron to an acceptor and a second pigment system was concerned with the acceptance of the electrons from this first acceptor They produced evidence to suggest that the second system was that in which photophosphorylation was concerned and deduced that cytochromes were probably concerned here

Our earlier observations with flash illumination can also be interpreted in terms of a mechanism involving two light steps In this article are further results on the effects of flash illumination with isolated chloroplasts which further clarify the mechanism involved

Ankistrodesmus was cultured in the manner described in ref 2 Chloroplasts were isolated from *Beta vulgaris* (perpetual spinach, Thompson and Morgan, Ltd) grown either in the field or in a greenhouse without close control of growth conditions The chloroplasts were isolated at 0° C by grinding in a medium containing 0 35 *M* sodium chloride, 0 17 *M tris* and 0 03 *M* $MgCl_2 6H_2O$ at *p*H 7 4, washed once in the grinding medium, and then re-suspended in the same medium diluted one in ten. The chloroplasts were kept on ice throughout the period before measurement A reaction mixture containing 10 μmoles $Fe_3(CN)_6$, 6 μmoles $MgCl_2 6H_2O$, 70 μmoles sodium chloride and 40 μmoles *tris* at *p*H 7 4 was made up to 2 5 ml , and when required 2 μmoles adenosine diphosphate and 40 μmoles inorganic phosphate added. For the purposes of uncoupling phosphorylation 10^{-2} *M* ammonium chloride was added In other experiments ferricyanide was replaced by 0 5 μmole phenol-indo 2,6-dichlorophenol Chloroplasts prepared in this way and kept at 0° C were found reasonably stable during the period required for the experiment Measurements could not begin for 40 min after preparation of the chloroplasts, since it was necessary to remove oxygen from the reaction mixture Two types of light flash were used a 'Mazda' discharge tube *FA*4 giving a flash of approximately 0 2 msec duration (short flash) and a Philips photoflux bulb *PF*60 approximately 30 msec (long flash) All other conditions of measurement were as described before except that the reaction vessel was maintained at 4° C

Whittingham and Brown found that the maximum yield from a pair of flashes was obtained with *Ankistrodesmus* when the short flash preceded the long flash by a dark interval of 0 7 sec at 25° C Some influence of the short flash on the yield from the long flash was detectable even with a dark separation of up to 15 sec Further work has shown that when the temperature was reduced to 4° C the yield from the long flash alone was much decreased , but the absolute maximal yield for a long flash preceded by a short flash was of the same order of magnitude as the maximum yield for the same two flashes at 20° C , except that the time between flashes for maximal yield was now 16 sec (Fig 1) A similar value was found for the time of separation of the two flashes for optimal production of oxygen from ferricyanide by chloroplasts isolated from spinach beet It is suggested that a dark thermal reaction, interposed between the two photochemical processes, is necessary for some conversion of the products of process 1 to become the reactants for process 2 The duration of the short flash is so brief that during the flash none of the product of the first reaction has been converted by the second Witt *et al* [7] have shown that the absorption changes in *Chlorella* at −150° C indicate that only one photochemical process predominates at low temperature Experiments reported here indicate a significant effect of temperature even within the physiological range The results in Fig 1, which compare the yield for two flashes as a function of their separation in time at 4° and 20° C , suggest that the thermal reaction proceeds more slowly but that its product has a greater half-life at the lower temperature This is consistent with the observations of Emerson *et al* [8], who showed that at lower temperatures photosynthetic efficiency was increased at longer wave-lengths in the far red consistent with an increased life-time at low temperature of the product of a reaction characteristic of shorter wave-length absorption

When phenol-indo 2,6-dichlorophenol was used instead of ferricyanide, the optimal separation between flashes was considerably shorter, being less than 5 sec at 4° C This indicates that dichlorophenol indophenol can result in production of oxygen without

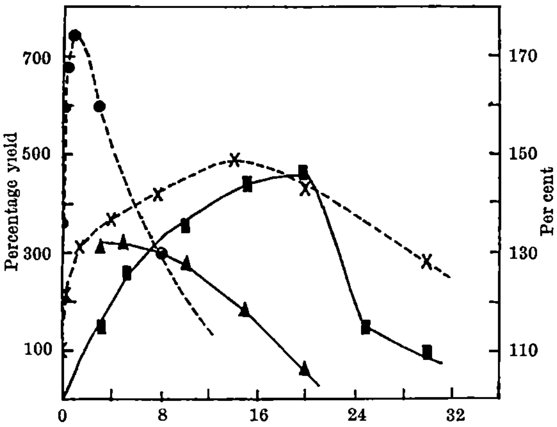

Fig 1 Relationship between the combined yield of oxygen for a short and long flash as a function of the dark time separating the two flashes The yield is expressed as a percentage of the sum of the yields from the two flashes given simultaneously ●, *Ankistrodesmus* cells in bicarbonate buffer at 20° C , ■, Isolated beet chloroplasts with ferricyanide at 4° C , ▲, Isolate chloroplasts with ferricyanide and ammonium chloride at 4° C (all right-hand ordinate), ×, *Ankistrodesmus* cells in bicarbonate at 4° C (left-hand ordinate)

proceeding through the same thermal reaction as is required for ferricyanide reduction Addition of catalytic amounts of indophenol (0 01 µmole) in the presence of ferricyanide (10 µmoles) changed the optimal time between flashes from that characteristic of ferricyanide alone to that characteristic of dye alone This is consistent with the results observed in continuous illumination[6], which Losada *et al* interpreted as indicating that reduction of dye could take place as a result of only one photochemical reaction

The difference in time of separation between flashes for optimal yield for ferricyanide and dye may be related to the fact that reduction of ferricyanide is accompanied by phosphorylation whereas that of dye is not Addition of adenosine diphosphate and inorganic phosphate to a system containing ferricyanide did not result in any significant change in the time of flash separation for optimal yield, but in the presence of ammonium chloride, which has been shown to uncouple the reduction of ferricyanide from phosphorylation[9], the separation in time was significantly shortened It became of the same order of magnitude as that in the presence of indophenol alone

The two types of flash used differ in spectral composition Further experiments, using monochromatic light flashes, have shown that with a long flash of 692 mµ a maximal effect is obtained with weak continuous illumination of 674 mµ A full investigation of the whole action spectrum is now in progress

These results are consistent with a mechanism of photosynthesis involving two light reactions separated by a thermal dark process The thermal dark process is apparently accelerated when phosphorylation does not accompany transfer of electrons Phosphorylation may be concerned directly in the thermal stage as previously suggested or if it accompanies the second photochemical step the rate of transfer of electrons from process 1 to process 2 must be slower in the presence of phosphorylation than in its absence

We are grateful to the Royal Society for a Government grant-in-aid of this investigation One of us (P M B) holds a postgraduate studentship of the University of London We are also grateful for a grant from the Central Research Fund of the University of London

SULPHATE TRANSPORT AND METABOLISM BY *DESULPHOVIBRIO DESULPHURICANS*

By Prof. C. FURUSAKA*

McGill-Montreal General Hospital Research Institute

LITTLEWOOD and Postgate[1] stated that the micro-organism *Desulphovibrio desulphuricans* is not freely permeable to anions such as sulphate and chloride They suggested that sulphate reduction occurs either outside the osmotic barrier or that the penetration of sulphate into the organism is regulated in such a manner that at equilibrium the ratio of the internal concentration of sulphate ions to the external concentration is so low that the analytical procedure used in their work could not detect penetration of the ion even at high external sulphate concentrations Skarzynski and Ostrowski[2] claimed that *Thiobacillus thioparus* takes up only the outer sulphur atom of thiosulphate, leaving the inner sulphur atom of thiosulphate outside the cell as sulphate ion

These two papers give an impression that the inorganic sulphur compounds are metabolized on the surface of the cells, even though sulphate and thiosulphate are the main energy-yielding substrate for these organisms

It was of interest to elucidate whether these organisms, which utilize inorganic sulphur compounds, actually metabolize their substrates at the surface of the cell outside the osmotic barrier

This communication is concerned with the problem of sulphate accumulation and metabolism in the cells of a strain of *Desulphovibrio*, which was isolated from a muck paddy field in Japan this organism plays a very important part in the reduction of sulphate to sulphide in the soil

The transport of sulphate into the cells was examined using a moderately thick suspension of cells (about 27 5 mgm. dry weight of cells was added to each reaction mixture , this corresponded to about 0 1 ml of packed cells per 2 ml of reaction mixture), as it was found that the ordinary thick suspension method[3] was not suitable for substances which are metabolized very quickly by the cell The cells were incubated with radioactive sulphate in Warburg vessels at 37° C in a *tris* buffer of *p*H 7 2, using hydrogen in the gas phase After incubation, the contents of each vessel were rapidly cooled with ice and then centrifuged at 18,000*g* for 14 min. in a refrigerated centrifuge The supernatant was removed by decantation for the estimation of sulphate and sulphide. The packed cells were rinsed three times with ice-cooled water very quickly to remove radioactive sulphate adhering to the wall of the centrifuge tube and to the surface of the packed cells

---

*Present address Institute for Agricultural Research, Tohoku University, Sendai, Japan

For the estimation of sulphate in the supernatant, an aliquot of the supernatant was placed in a test-tube and to it was added one drop of *N* hydrochloric acid Then the test-tube was put in a boiling water-bath for 2 min so as to eliminate hydrogen sulphide The solution was diluted ten times with distilled water, 0 5 ml of the diluted solution was placed on an aluminium plate and dried by an infra-red lamp The radioactivity on the plate was measured by a Geiger–Muller counter and expressed as the amount of sulphate in the reaction mixture

For the estimation of sulphide in the supernatant, 1 ml of the original supernatant was strongly acidified by hydrochloric acid in a distillation apparatus and the hydrogen sulphide evolved was driven into a zinc acetate solution, contained in a volumetric flask, by bubbling nitrogen gas through the apparatus for 1 hr The sulphide content of the zinc acetate solution was estimated by St Lorant's methylene blue method[4] The radioactivity of sulphide-sulphur was estimated by measuring the radioactivity of methylene blue adsorbed on carbon powder

The packed cells were extracted with 10 ml of 5 per cent trichloroacetic acid solution at 0° C An aliquot of the extract was dried on a steam-bath so as to drive off the hydrogen sulphide and almost all the trichloroacetic acid, then the residual organic matter in it was oxidized completely by hydrogen peroxide The residues were dissolved in a known amount of water and applied to the estimation of sulphate in the packed cells For this estimation an aliquot of the solution thus prepared was put on an aluminium plate and dried The radioactivity on the plate was measured and it was expressed as the amount of sulphate in the packed cells

For the estimation of sulphide in the packed cells, they were transferred into the distillation vessel using about 2 ml of water and the suspension strongly acidified by hydrochloric acid The hydrogen sulphide thus evolved was treated by the same procedure as was the supernatant for the estimation of the radioactivity of the sulphide-sulphur

In this article, the term 'transport' will be used for the description of inflow and outflow It should also be mentioned that the term 'accumulation' will be used to indicate the result of both transport and reduction

A typical result of sulphate accumulation in the cells is shown in Fig 1*a* The concentration of sulphate in the packed cells was found to be higher than that of the medium at a certain period of the reaction At the peak of this accumulation, the sulphate concentration in the packed cells was calculated to be 145 per cent greater than that of the reaction medium at that time, or 28 per cent greater than the initial sulphate concentration This indicates that there is a distinct accumulation of sulphate in the cells

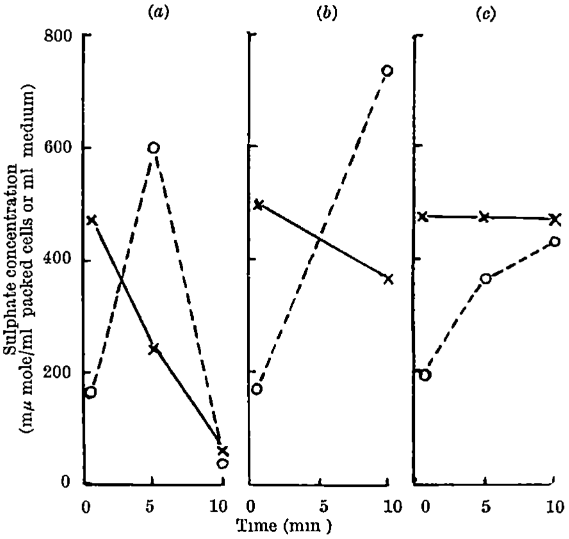

Fig 1 Sulphate accumulation in the cells ○---○, Sulphate concentration in the cells (mμ mole/ml packed cells) ×—×, Sulphate concentration in the reaction mixture (mμ mole/ml reaction medium)

(*a*) without selenate, (*b*) with *M*/16,500 selenate, (*c*) with *M*/1,100 or *M*/5,500 selenate

Each vessel contained 1 0 ml of *M*/20 *tris*-hydrochloric acid buffer (*p*H 7 2), 0 1 ml of *M*/1,000 phosphate buffer, 0 1 ml of magnesium chloride, 0 5 ml of cell suspension (corresponds to 0 1079 ml packed cell volume), 0 3 ml of water, 0 1 ml of *M*/100 sodium sulphate-^{35}S, and 0 1 ml of sodium selenate (*M*/750, *M*/250 or *M*/50 corresponding to *b*, *c* or *c*, respectively) In the centre well 0 3 ml of potassium hydroxide–pyrogallol solution was placed Total volume was 2 2 ml Sodium sulphate and sodium selenate were placed in a side-arm and were added to the reaction mixture at zero time

The mean velocity of sulphate transport, which corresponds to the mean velocity of disappearance of sulphate from the medium, and that of accumulation of sulphate in the cells, were calculated from the values obtained after 30 sec and 5 min in Fig 1*a* The mean velocity of sulphate transport was calculated to be 1,022 mμ mole/ml packed cells/min, dividing the amount of sulphate which disappeared from the medium (470 − 244 = 226 mμ mole/ml reaction mixture) by time (4 5 min) and the volume of packed cells (0 0491 ml), which corresponds to 1 ml of the reaction mixture On the other hand, the mean velocity of sulphate accumulation was calculated to be 96 6 mμ mole/ml packed cells/min, dividing the amount of sulphate accumulated in the cells (435 mμ mole/ml packed cells) by the time (4 5 min) These figures indicate that the sulphate transport is about eleven times more rapid than sulphate accumulation, that is, almost all the sulphate transported into the cells is reduced quickly and only a small part of the sulphate is left in the cells It must be borne in mind that the amount of sulphate accumulated in the cells is the result of two phenomena transport and reduction

It might be possible to show much more accumulation of sulphate in the cells if a way could be found to diminish the velocity of sulphate reduction without affecting the velocity of sulphate transport As a trial, the hydrogen gas phase of the reaction vessel was replaced by helium The helium gas was passed through for 2 min, with a consequent reduction of the partial pressure of the hydrogen gas Much greater accumulation of sulphate in the cells was observed with a helium–hydrogen gas phase than in the pure hydrogen phase, even though both velocities of sulphate reduction and transport were diminished It was also observed that sulphate, once accumulated in the cell, passes into the medium rapidly after sulphate reduction has stopped due to the lack of a hydrogen donor

More detailed experiments were conducted concerning the fate of the sulphide The concentration of sulphide in the cells was found to be always two to six times higher than that in the medium, even though it was much lower than that of sulphate The highest concentration observed in the packed cells was about 100 mμ mole/ml packed cells Changes in the concentration of sulphide in the cells follow that of sulphate

Selenate is known as a competitive inhibitor of sulphate reduction[5] It is also known that selenate competes with sulphate by the formation of a very unstable transient compound with adenosine triphosphate in the presence of sulphurylase[6] The effect of selenate inhibition was examined at different concentrations When *M*/16,500 selenate solution was used, a higher accumulation of sulphate in the cells was observed than in the cells without selenate, even though the velocity of sulphate accumulation was lowered (Figs 1*b* and 1*a*) The inhibition of sulphate transport and sulphate reduction calculated from the Figs 1*a* and 1*b* were 80 per cent and 85 per cent respectively. These values indicate that sulphate transport and reduction were inhibited by selenate, and the difference between the rates of inhibition of both reactions by selenate was very slight When the concentration of selenate was high enough to stop the reduction almost completely (95 per cent inhibition of sulphate reduction), no accumulation of sulphate in the cells was observed (Fig 1*c*) From these results the following possibilities are suggested. either (*a*) sulphate uptake is associated with sulphate reduction, or (*b*) selenate inhibits transport of sulphate directly.

To test whether sulphate transport is associated with sulphate reduction, experiments with oxygen were carried out Oxygen is a strong inhibitor of the metabolism of this organism When oxygen is used in the gas phase, the accumulation of sulphate in the cells and the reduction of sulphate are inhibited completely Further confirmation is seen in the results of diffusion experiments carried out at 0° C It was observed that 30 per cent of the packed-cell volume took up sulphate within the first 30 sec, but no marked increase of sulphate in the cells was observed in the following 30 min This figure, 30 per cent of the packed cell volume, corresponds to the inter-cellular volume of packed cells of *Desulphovibrio* (27 3–33 6 per cent as described by Littlewood and Postgate[1]) Even though there was observed a slight increase in permeable volume in 30 min, the final observed value of 36 8 per cent is still far from the percentage of the water content of the packed cells (76 3 per cent w/v) Therefore, little diffusion of sulphate into the cells occurs at 0° C and it is negligible compared with the velocity of sulphate reduction

The suggestions of Littlewood and Postgate[1] already cited seem to be only partially true There was no evidence for the idea that sulphate reduction might occur outside the osmotic barrier of the cell The main differences between our experimental conditions and those of Littlewood and Postgate are the presence of a hydrogen donor necessary for the reduction of sulphate and the low concentration of sulphate used in the reaction mixture (*M*/2,200) When a higher concentration of sulphate (*M*/220) was used, it was very difficult to observe any distinct accumulation of sulphate in the cell, probably because the concentration of sulphate in the medium was of the same order as the saturation concentration of the cells, the difference between the two being too small to be detected

My results show that *Desulphovibrio* is not freely permeable to sulphate, this being indicated by the results obtained using the following experimental procedures (*a*) inhibition by selenate, (*b*) oxygen inhibition of sulphate reduction, and (*c*) diffusion at 0° C Thus it must be concluded that (1) a significant accumulation of sulphate occurs in the cell, (2) sulphate must be metabolized inside the cell; and (3) the transport of sulphate is associated with the reduction of sulphate

I thank Prof J H Quastel for his valuable advice and interest in this work, and also the U S National Science Foundation for financial aid which made this work possible

ANTIGENICITY OF PENICILLIN AND ITS RELATION TO ALBUMIN BINDING

By Dr TOSHIO TORII, and Dr. YOSHIHI KOHORIUCHI
Hokkaido University Medical School, Sapporo

ANAPHYLACTOID reactions to penicillin are most commonly observed among severe immediate hypersensitivities to antibiotics[1] Reagin type of antibody was reported to cause these anaphylactoid reactions[2]. However, experimental hypersensitivity to penicillin has not been established by actual demonstration in animals In this article we present a method to induce active and passive anaphylaxis to penicillin in guinea pigs and discuss the mechanism of antigenic binding of penicillin to albumin

The method used to induce active anaphylaxis in guinea pigs to penicillin was as follows Equal volumes of 100,000 U/ml of penicillin *G* and 10 mgm/ml of recrystallized egg white albumin or horse serum albumin were incubated at 37° C for 24 hr The precipitates obtained by incubation were centrifuged and dissolved in saline to the original volume and adjusted to *p*H 7 6–7 8 For the sensitization 0 1 ml of this solution of penicillin–albumin complex was injected subcutaneously into guinea pigs twice weekly for a total of 5–10 times After 3 weeks

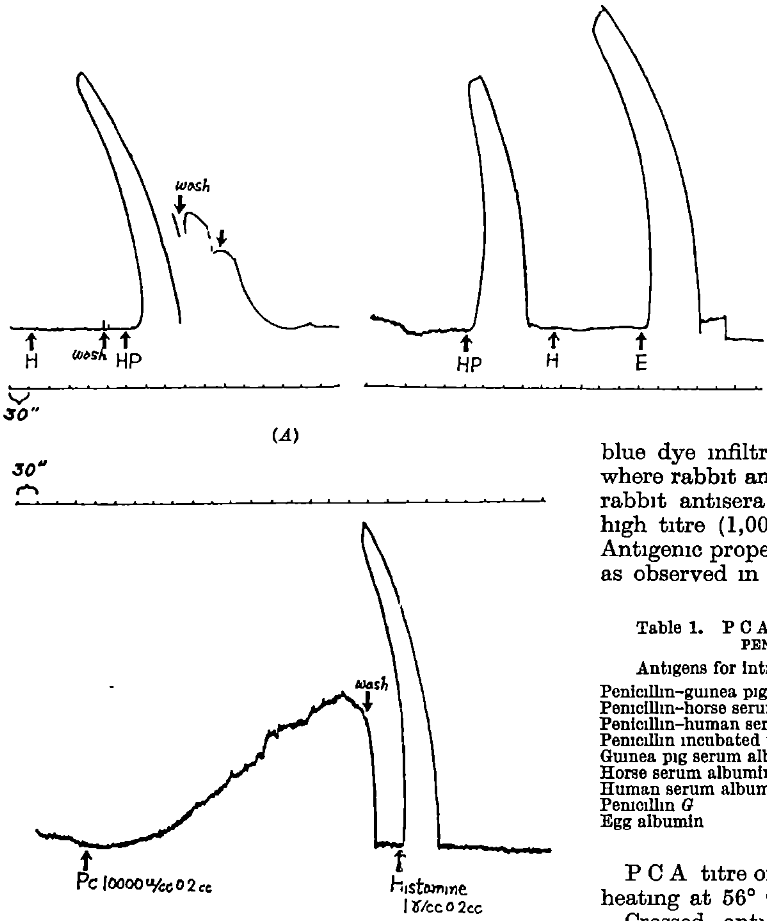

Fig 1 Schultz-Dale's ileum contraction test in guinea pig sensitized with penicillin–egg albumin complex (*A*) *H*, horse serum albumin, *HP*, penicillin–horse serum albumin complex, *E*, egg albumin, (*B*), *PC*, penicillin

of incubation, as shown in Fig 1*A*, the ileum of guinea pig sensitized with penicillin *G*–egg albumin complex showed a typical anaphylactic contraction as a result of contact with penicillin-horse albumin complex and egg albumin, but such contraction was not caused by horse albumin Penicillin-guinea pig serum albumin complex also can be used for the sensitization and the *in vitro* challenge

Plain penicillin *G* did not cause the anaphylactic contraction, or an atypical slow contraction was observed as shown in Fig 1*B* However, after pre-incubation with penicillin *G* any contraction caused by penicillin *G*–albumin complex was inhibited By use of the intravenous challenge method positive results were obtained only with penicillin–albumin complex and not with plain penicillin From these results penicillin appears to be a simple haptene and needs to be bound with albumin in order to gain a complete antigenicity.

Albumins to be combined in this method are not different according to their origins, in other words, they are exchangeable for sensitization and challenge.

Passive Cutaneous Anaphylaxis in Guinea Pigs

Passive cutaneous anaphylaxis (P C A) in guinea pigs by use of Ovary's method[3] was applied to test antigenicity of penicillin and closely related substances 3 ml of penicillin–egg albumin complex, 1 ml of dehydrated lanolin and 8 ml of liquid paraffin were mixed to make antigen for the sensitization of rabbit A total 0 2 ml of the mixture was injected into each foot pad and thereafter 1 ml subcutaneously once a week for a total of 10 times One-tenth ml of arbitrary diluted rabbit antiserum was injected intradermally into shaved abdominal area of guinea pigs After 5–6 hr , 1 ml of penicillin–albumin complex (2 5 times dilution of the complex antigen above described) and 1 ml of 0 5 per cent Evans's blue were injected into jugular vein Within 30 min blue dye infiltration was observed in the skin area where rabbit antiserum was previously injected All rabbit antisera of 8–10 weeks sensitization yielded high titre (1,000 times dilution) of P C A reaction Antigenic properties of penicillin were simple haptene as observed in the ileum contraction test (Table 1)

Table 1. P C A IN GUINEA PIGS WITH RABBIT ANTIBODY TO PENICILLIN–EGG ALBUMIN COMPLEX

Antigens for intravenous challenge	Results
Penicillin–guinea pig serum albumin complex	+ + +
Penicillin–horse serum albumin complex	+ + +
Penicillin–human serum albumin complex	+ + +
Penicillin incubated with human gamma globulin	—
Guinea pig serum albumin	—
Horse serum albumin	—
Human serum albumin	—
Penicillin *G*	—
Egg albumin	+ + +

P C A titre of rabbit antibody was unchanged after heating at 56° C for 4 hr

Crossed antigenicity to various penicillin derivatives and degradation products were tested by the P C A method. Penicillin *O* (allylmercaptomethyl-penicillin), penicillin *V* (phenoxymethyl-penicillin) and benzethicillin (dimethoxyphenyl-penicillin) gave the same positive results as penicillin *G* Exceptionally, phenethicillin (DL-phenoxyethyl-penicillin) needed acidification to make combination with albumin in order to cause positive P C.A reaction

Degradation products such as penicilloic acid, penicillic acid and penicillenic acid incubated with albumin gave no P C A reaction against the antibody to penicillin *G*–albumin complex, while inhibition was observed to result from antiserum pre-incubated with these degradation products.

Mechanism of Antigenic Binding of Penicillin to Albumin

After incubation of penicillin *G* and albumin at 37° C for 24 hr , the *p*H of the medium decreased from 6 2 to 4 6–4 8 By making the medium alkaline the P C A titre was almost completely lost On the contrary, by acidification the binding process was accelerated The relation between decrease of *p*H and P C A titre is shown in Table 2

An incubated mixture of penicillin *G* and serum did not induce P C A but after acidification and dialysis positive reaction was obtained Tissue homogenate such as liver, spleen, lung and skin gave no positive result, with the exception of the exudates, which usually have acid reaction From these observations it is obvious that penicillin may block alkaline

Table 2 RELATION BETWEEN DECREASE OF *p*H AND TITRE OF P C A

Antigens	*p*H before incubation	*p*H* after incubation	Titre of† P C A
Penicillin *G* + Albumin	6 2	4 4	1,000
Penicillin *G* + Albumin (acidified)	4 6	4 6	1,000‡
Penicillin *G* + Albumin (alkalized)	7 2	5 8	1
Phenoxyethylpenicillin + Albumin	6 2	5 6	0
Phenoxyethylpenicillin + Albumin (acidified)	4 6	4 6	1,000
Penicillin *G* + Normal serum	7 2	7 0	0
Penicillin *G* + Normal serum (acidified)	5 0	4 4	100
Penicillin *G* + Dialysed serum	6 4	5 0	1,000
Penicillin *G* + Pleural exudate	6 2	5 2	100

* 24 hr incubation at 37°C
† maximum dilution of antiserum
‡ 30 min incubation

radicals of the albumin molecules from the antigenic binding, whereas acidification accelerates this reaction By means of penicillin *G* labelled with sulphur-35 the number of molecules of penicillin bound to one molecule of the albumin complex antigen was estimated as 44 5 (mean of 4 experiments) In autoradiographs of paper electrophoresis with serum or exudate, penicillin was found to be bound to albumin and not globulin

A Peculiar Protein found in the Serum of Atopic Patients

The serum from patients with anaphylactoid reaction or angioneurotic œdema had strong capacity for antigenic binding without acidification This binding occurred within 30 min and was independent of the presence of any reagin to penicillin (Table 3)

Table 3. CAPACITY OF ANTIGENIC BINDING OF SERUM FROM NORMAL SUBJECTS AND PATIENTS

	Antigens	Duration of incubation	Terminal *p*H	Titre of P C A
1	Normal serum + Penicillin *G* (5 cases)	24 hr	6 8–7 2	0
2	No 1 serum* + Penicillin *G*	24 hr	7 0	1,000
	+ Penicillin *G*	30 min.	7 0	100
	„ + Penicillin *V*	24 hr	7 0	1,000
	„ + Phenoxyethyl-	24 hr	7 0	1,000
	„ penicillin	24 hr	7 0	1,000
	„ + Penicilloic acid	24 hr	5 8	0
	Heated serum (56° C , 4 hr) + Penicillin *G*	24 hr	7 0	1,000
3	No 2 serum† + Penicillin *G*	24 hr.	6 8	1,000
4	No 3 serum‡ + Penicillin *G*	24 hr	7 0	1,000

* Patient No 1 with anaphylactoid reaction to penicillin, reagin to penicillin (+++)

† Patient No 2 with anaphylactoid reaction to sulpha drug, reagin to penicillin (—)

‡ Patient No 3 with angioneurotic œdema, reagin to penicillin (—).

From these results and observations we assumed the existence of a peculiar protein in such patients which has strong capacity of antigenic binding to some kind of haptene so that atopic patients acquire hypersensitivities very easily to many kinds of haptenes

Physicochemical properties of this protein and implications respecting haptenes other than penicillin remain to be investigated

INHERITED CASEIN VARIANTS IN COW'S MILK

By Dr. R. ASCHAFFENBURG

Chemistry Department, National Institute for Research in Dairying,
Shinfield, Berkshire

PAPER electrophoresis has been used successfully to demonstrate the occurrence of genetically distinct types of β-lactoglobulin[1,2] and α-lactalbumin[3] in cow's milk With the aid of the same method, evidence has now been obtained for the existence of gene-controlled variants of the β- and γ-components of the principal milk protein, casein

Paper electrophoresis of casein in conventional buffer systems presents difficulties which stem from the anomalous behaviour of α-casein Zhdanova and Vlodavets[4] and Libbey and Ashworth[5] have shown that this fault can be eliminated by adding urea to the buffer, but they did not obtain a clean separation of β- from α-casein Such a separation has now been achieved by working with a buffer system made up of constituents with which casein is associated under natural conditions, namely, citrate and phosphate Briefly, the technique consists of electrophoresis at 4° C in a buffer of *p*H 7 15, made up of 0 913 gm citric acid monohydrate, 3 56 gm disodium hydrogen phosphate and 360 gm urea a litre Using the horizontal type of apparatus described by Kohn[6], a constant 180 V is applied for 5 hr to two sheets of Whatman 3 *MM* paper (10 × 20 cm), each carrying three or four samples deposited across the centre of the sheets Samples are prepared by isoelectric precipitation of the casein from 10 ml of skim milk, addition of 2 gm. urea to the centrifuged and washed casein, and dispersion with water to a final volume of about 5 ml of a slightly opaque solution

As shown in Fig 1, the procedure resolves the protein into two α-casein bands, the slower-moving one probably representing the κ-casein of Waugh and von Hippel[7], a single β-band, and two γ-bands which move towards the cathode Contrary to the other components, the γ-caseins—very clearly shown in the chosen examples—vary markedly in strength from milk to milk, as will be discussed later Otherwise rather uniform results were obtained in comparing the casein patterns from the milk of individual cows A departure from the norm emerged during the examination of a series of samples from one-egg twins of different breeds, kept at the Institute milk from each of a pair of cross-bred Jersey–Guernsey cattle (*O*37/38) was found to contain two β-casein

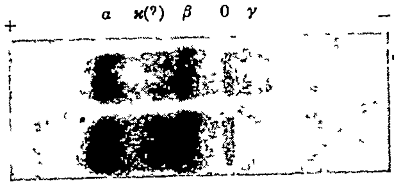

Fig 1. Separation of casein by paper electrophoresis 0 = origin (photographed in transmitted light)

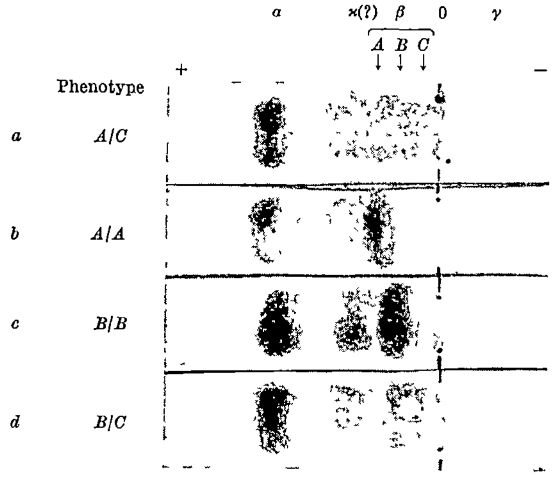

Fig 2 β-Casein variants 0 = origin (photographed in reflected light)

components (*B* and *C*, Fig 2*d*), migrating more slowly than the usual single component (*A*, Fig 2*b*) The fact that the 'anomaly' occurred with both twins, suggested a genetical basis, and led to the collection of samples at the farm of origin with the surprising result that, of 21 cows examined, only 3 produced β-casein *A* Three additional variants, *A* and *C* (Fig 2*a*), *A* and *B* (not shown), and *B* only (Fig 2*c*) were found among the remaining samples The older animals at this farm were Guernseys, the younger ones *F*1-crosses with Jersey sires The male line was traced back to a small pedigree Jersey herd with ten cows in milk four of these produced β-casein *A*, the others *B* or *A* and *B* combined

Examination of the available family data showed the results to be in accord with the concept of the existence of three alleles of a gene (locus symbol β-*Cn*), giving rise to six possible phenotypes of which all but one, *C*/*C*, have so far been observed Some relevant relationships for the twins *O*37/38 are given in Fig 3 They show that all three alleles are present in the Guernsey stock, and that the Jersey sire (III) as well as its sire (II) and grand sire (I) transmit the *B*-allele which, as mentioned here, is prevalent at the Jersey farm

Though still in its early stages, a survey of milk samples from cows of other Channel Island herds has already shown that the observations connected with the twins *O*37/38 are not to be regarded as rare anomalies In tests of samples from seven Guernsey herds, both the *B*- and *C*-alleles were found in one herd and the *B*-allele in another; and in one of three Jersey herds the *B*-allele occurred quite frequently These herds are now under more detailed investigation, and further data on Jersey cows are being collected to ascertain whether the *C*-allele, so far only found in Guernsey milk, occurs in that of Jersey cows as well Information is also required on the possible occurrence of the β-casein polymorphism in other breeds So far only Friesian cows have been examined in sufficient number to suggest that the polymorphism might be restricted to Channel Island cattle This would be highly interesting, since Bangham[8] has shown that hæmoglobin polymorphism among British cattle breeds is confined to Channel Island (and South Devon) animals It is true that during tests on milk from more than a hundred Friesian cows, a few instances were observed in which the *B*-allele was present, but these were so isolated that they might well be merely the consequence of cross-breeding with Channel Island cattle

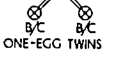

Fig 3 Pedigree of one-egg twins (*O*37/38), showing 5 of the 6 possible phenotypes of β-casein

As mentioned earlier, the two γ-casein bands, obtained from the milk of individual cows, were found to vary considerably in strength, as illustrated by Figs 1 and 2 (The photographic reproduction conceals the fact that weak bands were present in all the examples shown in Fig 2) In some samples, the bands appeared to be completely absent The statement that this variability has a genetical basis is founded largely on the observation that, in comparisons of the strips prepared from the milk of eighteen pairs of one-egg twins, γ-caseins of identical appearance and strength were obtained within each single pair, while the variability between the pairs covered the whole range These findings suggest the existence of a metabolic polymorphism of the kind described by Allison[9] as "that in which one genotype has a particular substance in relatively large amounts while other genotypes have smaller amounts or lack it altogether" There has been no indication that this polymorphism differs from breed to breed. Interpretation of the results is far from easy, when the γ-casein bands are very weak, and detailed study of this polymorphism has been postponed pending the development of a more searching technique producing the weak γ-caseins in higher concentration Such a development seems necessary, as the simple expedient of applying more than the usual amounts of total casein to the filter paper results in the formation of blurred, poorly resolved bands

Casein is present in cow's milk in the form of a colloidal complex It appears from the foregoing that several independent genes are involved in its elaboration by the mammary gland, and that the 'classical' sub-division of the complex into α-, β- and γ-caseins is justified and meaningful

I am grateful to my colleagues of the Dairy Husbandry Department, Dr F H Dodd and W S Mitchell, and to N T Culling and his staff at the Reading Regional Milk Records Office, Milk Marketing Board, for the collection of milk samples and information, and to Miss J E Cooper for skilful technical assistance

COMPARISON OF TRANSDUCTION VERSUS TRANSFORMATION OF LINKED MARKERS IN *BACILLUS SUBTILIS*

By ERELA EPHRATI-ELIZUR and MAURICE S. FOX

The Rockefeller Institute, New York, 21

WITH *Bacillus subtilis*, it has been possible by transformation to demonstrate linkage between mutant sites (markers) responsible for tryptophan and histidine requirements[1,2] and between markers responsible for tryptophan and tyrosine requirements[3]. The degree of the linkage is determined by comparing the frequency with which bacteria which have been transformed to independence of one required metabolite have been simultaneously transformed to independence of the other[4]. Due to the low frequency of transformation in these experiments, cells are rarely transformed simultaneously for two unlinked markers. As a result of the observation of phage-mediated transfer of genetic material (transduction) in *B. subtilis* by Thorne[5], it has become possible to compare the degree of linkage between a given pair of genetic markers introduced either by deoxyribonucleate mediated transformation or by bacteriophage-mediated transduction.

The lysogenic *B. subtilis W*23 *L*–9, carrying a transducing phage, was kindly provided by Dr. C. B. Thorne. Transducing phage suspensions were prepared in broth after confluent lysis in soft agar plates seeded with both the phage and the sensitive wild-type bacterial strain *W*23 (ref. 6). Shaking with chloroform followed by a low-speed centrifugation was sufficient to remove the bacteria from these suspensions. The phage was partially purified by centrifugation at 13,000 r.p.m. for 80 min. Sterile glycerol was added to the phage suspension to make 10 per cent by volume and 1 ml. samples were stored in a freezer cabinet at – 20° C. The phage titre was determined by plating on tryptone agar plates supplemented with 0.5 per cent glucose and 0.1 per cent yeast extract, using the agar layer method[6]. The transduction procedure described by Thorne was modified in the following way. Mutant bacterial cultures were grown in tryptone broth supplemented with 0.5 per cent sodium chloride and 0.5 per cent glucose, for 5 hr. at 37° C., with aeration. To 1 ml. samples, sterile glycerol was added to make 10 per cent by volume, and the cultures were kept frozen at – 20° C. until use. For transduction experiments, the cultures to be transduced were allowed to thaw in an ice bath and either diluted 1/10 into fresh medium and incubated for 5 hr. or centrifuged after being thawed, re-suspended in 1 ml. of fresh broth and incubated with aeration for 60 min. Following either of these treatments, 0.1 ml. of a phage suspension was added and the cultures were incubated with aeration for 45 additional minutes after which aliquots were spread on plates containing minimal medium[2]. Control platings of the phage suspensions showed no bacterial contamination; deoxyribonuclease treatment of these suspensions had no effect on transduction yields. In the transduction tubes, the bacterial densities varied from 2 to 5 × 10^8/ml. Phage densities were between 2 and 3 × 10^8/ml. All incubations were at 37° C. The procedure for transformation has been described elsewhere[2].

It can be seen in Tables 1 and 2 that the frequency with which the respective pairs of markers are transferred jointly is very nearly the same, when they are introduced either by transformation or transduction. This is true for both linkage groups that have been examined, tryptophan–histidine and tryptophan–tyrosine. In Table 3 a comparison has been made between frequencies of transformation and transduction of tryptophan, and a number of markers located in another histidine region showing no evidence of linkage to tryptophan. The four mutant histidine sites represented in the first four strains have been shown by transformation to be

Table 1. LINKAGE BETWEEN HISTIDINE AND TRYPTOPHAN MARKERS AND BETWEEN TYROSINE AND TRYPTOPHAN MARKERS BY TRANSDUCTION AND TRANSFORMATION

The cultures treated with deoxyribonucleate (DNA) or phage were plated on minimal agar supplemented with either histidine (his) or tryptophan (tryp), in the case of the his-tryp mutants, and with tyrosine (tyr) or tryptophan in the case of tyr-tryp mutants. Colonies selected for independence of one metabolite were tested for independence of the other by streaking on unsupplemented minimal agar plates. *W*, wild-type bacterial strain *W*-23.

* Number of transduced or transformed colonies on plates, bearing approx 10^7 treated bacteria

closely linked to each other[2] The tryptophan mutation is identical with that of the four mutants in Tables 1 and 2. It can be seen that in transduction, the frequencies of the genetic transfer of the histidine[1,8-10] region are less than 10 per cent of that of the tryptophan marker, whereas by transformation these markers are transferred at about the same frequency as is the tryptophan marker In one mutant strain, 168–32, requiring tryptophan and histidine, neither mutational site has been precisely located This mutant can neither be transformed nor transduced to histidine independence

The results presented show that the ratio of the frequency with which a pair of markers is introduced simultaneously to the frequency of introduction of a single marker is the same, within experimental error, whether these markers are introduced by transformation or transduction A group of histidine markers, shown to be unlinked to tryptophan by transformation, is also found to be unlinked by transduction The frequencies of transfer of these latter histidine markers in comparison with tryptophan were always markedly lower in transduction than in transformation experiments Differences in frequency of transduction of different markers have been described in *S typhimurium*[7]

Thus it has been demonstrated that, for several linked pairs of markers, the process of genetic incorporation as expressed in the degree of linkage, is remarkably similar whether the transfer is mediated by purified deoxyribonucleate or by transducing bacteriophage

We wish to thank Dr R D Hotchkiss for the interest he has shown in this investigation

EXTRACELLULAR ESTERASE OF GROUP A STREPTOCOCCI

Esterase in Extracellular Concentrates of Group *A* Streptococci and the Homologous Antibody

A CARBOXYLIC acid esterase sensitive to diisopropylfluoridophosphate (DFP) has been found in extracellular concentrates of group *A* streptococci The existence in various sera of antibodies against this esterase is described These antibodies precipitate the streptococcal esterase but do not block its activity, a situation identical to that found by Uriel[1] with the esterases of human serum and their corresponding horse antibodies

The enzyme was demonstrated by the following method Electrophoresis of ten-fold to a thousand-fold concentrates of the extracellular products of group *A* streptococci was made from holes or slots in agar gel for 75 min in 10 × 4 cm slides by the Grabar and Williams technique[2] or for 45 min by the microscope-slide modification of Scheidegger[2] Following electrophoresis or immunoelectrophoresis, the esterase activity was revealed by a technique described in ref 1 The principle of this method[3] involves the splitting of the substrate β-naphthyl acetate and coupling with the azo dye, diazo blue *B*, the esterase appearing as a red-blue area (Fig 1) So far, esterase activity has been demonstrated in extracellular concentrates of six strains of group *A* streptococci (Table 1) The concentrated uninoculated broths gave negative results

The esterase activity does not appear to be due to the following known streptococcal products, streptolysins *O* and *S*, streptokinase, proteinase, deoxyribonuclease, diphosphopyridine nucleotidase (DPNase), and erythrogenic toxins *A* and *B* Of these the most interesting is proteinase, because it is known that some proteolytic enzymes like trypsin have esterase activity

The electrophoretic mobility of the esterase was similar to that of streptolysin *O* (ref 4) However, the two activities can be differentiated as will be shown here The two products may share another property, as shown in Table 1 Concentrates of lot 32369-26, which had been prepared by filtration of the culture through a Berkefeld filter, showed no esterase activity, a similar adsorption had occurred with the streptolysin *O* of this lot[5]

Investigations of the effects of inhibitors were carried out by the method in ref 1 DFP at 10^{-4} *M* inhibited the esterase activity, while 10^{-4} *M* *p*-chloromercuribenzoate was without effect The opposite results were obtained with streptolysin *O* (ref. 4)

Table 1 ESTERASE ACTIVITY OF VARIOUS STREPTOCOCCAL PREPARATIONS

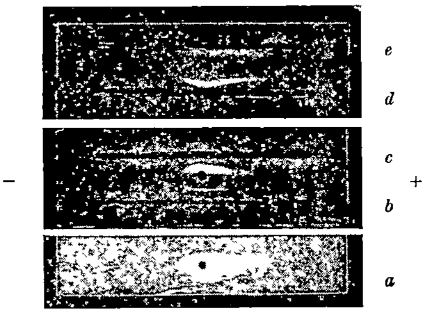

Fig 1 *a*, Electrophoresis of extracellular concentrate Wilson-1 , *b–e*, immunoelectrophoresis of extracellular concentrate Wilson-1, *b*, normal horse serum, *c*, normal human serum No 1, *d*, normal human serum No 2, 1 100, *e*, normal human serum, No 2, 1 1,000

In immunoelectrophoresis, the various sera placed in the trenches included six normal adult sera, a 10 per cent human γ-globulin (Centre de Transfusion, Réanimation de l'Armée), one standard horse antistreptolysin *O* serum (1,500 units/ml Institut Pasteur) and scarlet fever antitoxin (horse), Lederle lot 1570–473 (ref 5) All these sera gave arcs of enzymic activity as shown in Fig 1, due to precipitation of antigen and antibody The arcs of precipitate before staining for esterase were not visible to the naked eye nor could they be observed after staining with azocarmine[6] A rabbit antiserum containing 1,500 units of antistreptolysin *O* and a rabbit antistreptococcal serum (type 1, precipitating) made with killed bacteria gave negative results in immunoelectrophoresis

That normal human serums can react with extracellular streptococcal antigens has been shown by Halbert *et al* and confirmed by others (ref 7), and the present findings confirm another antigen–antibody system

Dr Tom Webb and Efstratios Avrameas of this Service made useful suggestions in the course of the work Sera were given by Drs R Wahl or A Eyquem of the Institut Pasteur Some streptococcal fractions were given by Dr A Bernheimer of New York University and Dr S P Halbert of Columbia University

Electrophoretic Mobility and Detection of Hæmolytic Activity of Streptolysins O and S in Agar-Gel

While investigating the extracellular esterase of group *A* streptococci, it became necessary to have a direct method for the demonstration of the electrophoretic mobility of streptolysins *O* and *S* A slight modification of the procedure of Uriel[8] for the direct detection of proteolytic enzymes after electrophoresis in agar-gel proved successful and is as follows The streptolysin preparations were placed in slots cut in agar on slides The streptococcal concentrates containing streptolysin *O* were either a crude thousand-fold concentrate of supernatants of broth cultures grown in dialysate broth[5] or a thirty-fold concentrate (as in ref 5) of an Institut Pasteur streptolysin from cultures of strain *S* 84 of Kalbak grown in infusion broth (given by Dr R Wahl, Institut Pasteur, Paris) Both streptolysin *O* preparations contained sufficient lysin in the reduced form, so that addition of cysteine was not necessary for activity, which was fortunate, since this reagent nullified the effect of one of the inhibitors (*p*-chloromercuribenzoate) used in the investigation That streptolysin *O* collected after 12–24 hr can exist in the reduced form without reduction was shown in the pioneering studies of Neil and Mallory[9] The nucleic acid induced streptolysin *S* was given by Dr A Bernheimer of New York University Electrophoresis in agar-gel was carried out for 45 min by the procedure in ref. 2 in a modified microscope-slide method of Scheidegger (see ref 2) Following electrophoresis, the slides were immersed in phosphate-buffered saline *p*H 6 5 (ref 10) for 15 min to convert the gels to isotonicity. The surface of the slides was then dried lightly with filter paper, and overlayed by means of a pipette with 2 ml of a 2 per cent washed human red blood cell suspension in melted 1 5 per cent agar in phosphate-buffered saline at 45–50° C When the overlay had hardened, the slides were placed in Petri dishes and incubated at 37° C In about 30 min the hæmolysis became visible, but the reaction was allowed to proceed for a total of 60 min As shown in Fig 2, streptolysin *O* migrated very slowly while streptolysin *S* exhibited rapid mobility, easily differentiating the two lysins

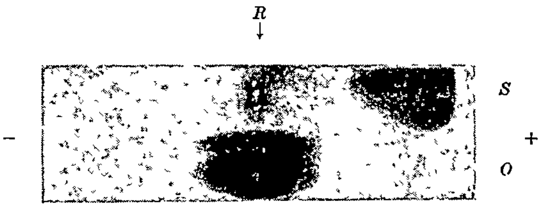

Fig 2 Electrophoresis of streptolysins *O* and *S* *R*, reservoir, top, streptolysin *S*, bottom, streptolysin *O* The dark areas are the hæmolysed zones There is an artefact at the reservoir of streptolysin *S* due to overlay of agar over the reservoir

The mobility of streptolysin *O* observed by the direct method apparently differs from the mobility described by Hanson and Holm[11] with the use of the 'basin overlay' and immunoelectrophoretic techniques and markedly differs with the mobility found by Halbert and Keatinge[7] with an immunoelectrophoretic method By including in the overlay of red blood cells sufficient antistreptolysin *O* (horse, Institut Pasteur), it was demonstrated that streptolysin *O* activity could be inhibited.

Some investigations of chemical inhibitors were carried out using the technique elaborated by Uriel[1] for the study of esterases in human serum Following the electrophoresis of streptolysin *O* or *S*, the slides were immersed in either 10^{-4} *M* di-isopropylfluorophosphate (DFP) or 10^{-4} *M* *p*-chloromercuribenzoate in buffered saline, and overlays of red blood cells in agar were made, but containing 10^{-4} *M* concentration of the inhibitors It was found that streptolysin *O* was inhibited by *p*-chloromercuribenzoate in accordance with the findings by Smythe and Harris[12] of the effect of mercury salts on this lysin, it was not inhibited by DFP The two inhibitors thereby differentiate streptolysin *O* from streptococcal esterase Streptolysin *S* was not inhibited by either *p*-chloromercuribenzoate or DFP To our knowledge these findings have not been reported before

It is planned for the future to carry out electrophoretic work on other bacterial hæmolysins, especially tetanolysin, pneumolysin and the O toxin of *Cl welchii*, all of which were shown by Todd[13] to have an immunological relationship to streptolysin O

This work was aided by a grant from the National Institutes of Health, Bethesda

A CELL FOR RAPIDLY MEASURING RESTRICTION TO DIFFUSION OF MACROMOLECULES THROUGH AGAR GELS OF VARIOUS PORE SIZES

By G K. ACKERS and R. L. STEERE

Plant Virology Laboratory, Crops Research Division, U S Department of Agriculture, Beltsville, Maryland

RESTRICTED diffusion of small proteins through stretched dialysis tubing has been investigated by Craig *et al* [1] This and other work indicated that restricted diffusion may be an effective tool for (*a*) size estimation of macromolecules in undefined or impure systems, (*b*) fractionation of components in such systems, and (*c*) tests of particle-size homogeneity in purified preparations In view of these possibilities we thought it advisable to extend measurements into the range of pore sizes which would be effective in restricting diffusion of virus particles.

Rapid and reproducible results are obtained by using diffusion cells of the construction shown in Fig 1 The inner chamber is made of glass A thin piece of 'Monofilament Saran' screening (*MS*-904, 51 mesh, 0 008 in yarn diam , National Filter Media Corp) is stretched across its bottom and cemented securely around the edge (The materials mentioned were purchased from the companies designated These sources are presented only for specific identification of the materials used No discrimination is intended and no guarantee of reliability implied) The mesh on the bottom of this inner chamber is then immersed to a depth of approximately 1 mm in a warm agar sol of accurately known concentration Sol is drawn swiftly by surface tension into the interstices of the 'Saran' mesh The chamber is withdrawn from the agar and excess sol is gently scraped from the bottom surface of the 'Saran' and from the outer rim of the chamber A thin film of agar (about 0 03 cm thick) is left in the mesh across the lower surface of the chamber This film is allowed to gel at room temperature and forms a continuous, sturdily supported membrane The cell is assembled with a rubber sleeve, a flat cover, a screw clamp, and an outer chamber of the dimensions shown The inner chamber is filled with buffer solution and closed securely with the screw clamp The membrane assembly is placed in contact with buffer in the outer chamber and allowed to 'mature' for 48 hr in a cold constant-temperature chamber The buffer in the inner chamber is then replaced by a buffered solution of the molecular species the diffusion of which is to be measured That in the outer chamber is replaced by fresh buffer at successive timed intervals and concentrations of the diffusates are assayed

Integration of Fick's first law for the boundary conditions of this system leads to equation (1) (ref 2)

$$\frac{DA}{l} = -\frac{V_i V_0}{t(V_i + V_0)} \ln \frac{(C_i - C_0)f}{(C_i - C_0)i} \qquad (1)$$

D is the diffusion coefficient l and A are the effective length and total cross-sectional area of pores in the

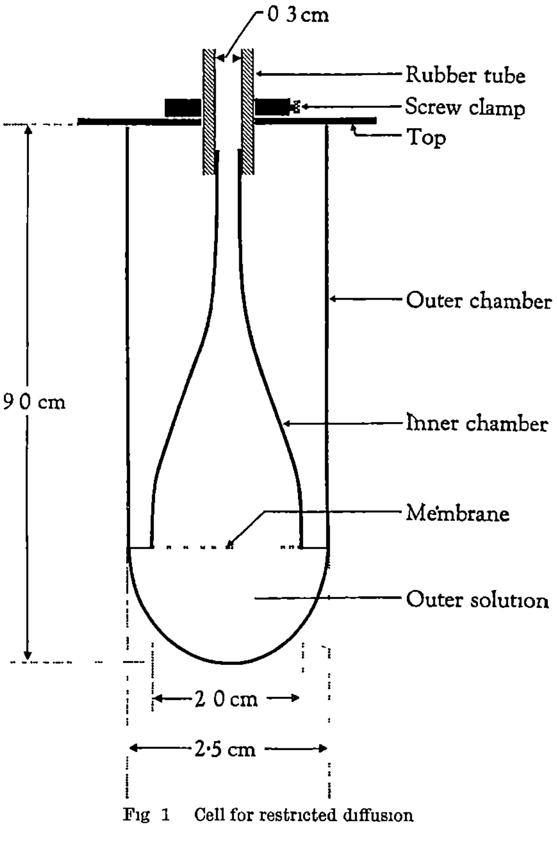

Fig 1 Cell for restricted diffusion

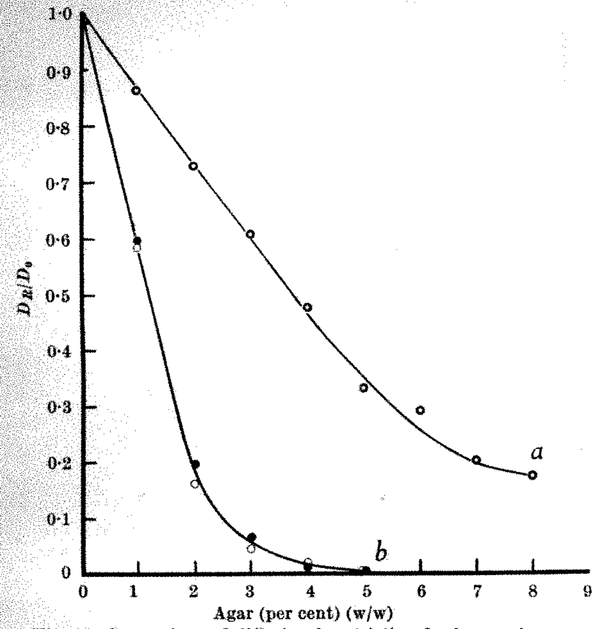

Fig. 2. Comparison of diffusional restriction for human hæmoglobin and southern bean mosaic virus particles. The restricted diffusion coefficients are plotted as percentages of the extrapolated diffusion coefficients against gel concentration. *a*, Human hæmoglobin; *b*, southern bean mosaic virus; ●, assay by ultra-violet absorbance; ○, assay by infectivity

membrane. V_i and V_0 are the respective volumes of the inner and outer solutions the concentrations of which are C_i and C_0; i and f refer to initial and final conditions; t is the duration of the experiment. In practice the quantity A/l is evaluated for each membrane by diffusion of a small molecular species the diffusion coefficient of which is known.

Representative data (averages of 4 determinations) for restricted diffusion of purified southern bean mosaic virus (0·27 mgm./ml.) and 1 per cent human hæmoglobin (2 × cryst., 9019, Nutritional Biochemicals Corp., Cleveland, Ohio) both in 0·0667 *M* phosphate buffer (*p*H 6·7) through a series of 'Ionagar No. 2' (Oxoid) membranes of different gel concentrations are shown in Fig. 2. The agar was made up at each concentration (w/w) in distilled water and autoclaved 15 min. at 15 lb./in.^{2} pressure. The cells were assembled and calibrated with 0·1 *M* sodium chloride (using $D_{20,w} = 1{\cdot}36 \times 10^{-5}$ cm.^{2}/sec.) (ref. 3). Behaviour of all cells conformed closely to equation (1). This indicates that transport through the gel under the experimental conditions used is at least predominantly diffusional.

Diffusion was carried out in a constant-temperature chamber at 8° ± 0·5° C.. Suspensions were assayed by ultra-violet absorbance at 2600 Å. (for southern bean mosaic virus) and 2800 Å. (for hæmoglobin). The southern bean mosaic virus diffusates were assayed also by infectivity tests. Results of these measurements agree closely with the absorbance values as shown in Fig. 2.

Values for restricted diffusion coefficients were calculated by using equation (1) for the two species of particles at each gel concentration. When these coefficients (corrected to water at 20° C.) were plotted against agar concentration and the curves extrapolated to zero gel concentration, the values obtained were $1{\cdot}23 \times 10^{-7}$ cm.^{2}/sec. for southern bean mosaic virus and $6{\cdot}6 \times 10^{-7}$ cm.^{2}/sec. for hæmoglobin. These values are in good agreement with the reported values of $1{\cdot}39 \times 10^{-7}$ cm.^{2}/sec. and $6{\cdot}9 \times 10^{-7}$ cm.^{2}/sec. (ref. 4). Fig. 2 shows the comparative diffusional restriction encountered by particles of these two types as the gel pore size is decreased with increasing agar concentration. In this graph, ratios of D_R (the restricted diffusion coefficient) to D_0 (the extrapolated coefficient) for the two particle-species at each gel concentration are plotted against the gel concentrations. It is clearly seen that the larger southern bean mosaic virus particles (28·0 mμ diam.[5]) were restricted to a much greater extent in their migration through the gel matrix than were the smaller (6·16 mμ diam.[6]) hæmoglobin particles.

Results of this investigation suggest that restricted diffusion by use of agar-gel membranes should be a particularly useful tool for the study of viruses. For example, although the hæmoglobin molecule diffuses only 4·5 times as fast as the southern bean mosaic virus particle under free conditions with only hydrodynamic restriction, it was found to diffuse 63 times as fast through a 4 per cent agar-gel membrane. With such separation between virus particles and other macromolecular components of tissue extracts, it should be possible to effect a high degree of purification by using a limited number of countercurrent steps under properly selected restrictional conditions.

We wish to express our appreciation to James M. Parsons for help in the initial stages of this work.

A part of this work was carried out in the laboratories of the Harding College Chemistry Department, Searcy, Arkansas, under the support of a Brown Hazen grant obtained through Research Corporation, New York.

AUTORADIOGRAPHY USING MELTED NUCLEAR EMULSION

By Dr. A. C. KULANGARA

Department of Embryology, Carnegie Institution of Washington, Baltimore 10, Maryland

AUTORADIOGRAPHY of tissue sections using melted emulsion may be carried out in two ways: the sections may be stained first, coated with nitrocellulose and emulsion and then processed, or the sections may be stained after photographic processing. During an investigation of rabbit uterus (labelled with carbon-14) by the first method, it was found that sections became de-stained in spite of considerable overstaining, and black deposits, ranging from a few silver grains to large aggregates, appeared

Table 1

Slide No.		Mean No. of grains ± stand. error in 1,380 μ^2		Mean No. of aggregates ± stand. error in 5,520 μ^2	Mean No. of grains ± stand. error over one nucleus
		Background	Over tissue		
1	Unstained sections covered with thin nitrocellulose coat	8·4 ± 0·59	16·0 ± 1·95	15·4 ± 2·05	
2	Unstained sections embedded in a thick nitrocellulose coat	6·0 ± 0·32	7·7 ± 0·76	none	
3	Sections stained in hæmatoxylin and covered with thin nitrocellulose coat	7·4 ± 0·71	18·1 ± 1·1	63·4 ± 5·71	15·75 ± 1·92
4	Sections stained in eosin and covered with thin nitrocellulose coat	7·1 ± 0·61	10·8 ± 0·76	22·2 ± 1·8	several

All sections were of non-radioactive rabbit uterus.

Grains were counted under oil immersion, in 1,380 μ^2 at a time, at least 10 such areas being counted for a sample. Aggregates were counted in 5,520 μ^2 at a time, four such areas being counted for a sample.

on slides. Discrete grains, indistinguishable from those caused by ionizing events, occurred in greater density near the aggregates.

The formation of aggregates has been reported by others[1,2], but discrete grains which may occur with or without aggregates do not seem to have received as much attention. Stains and other solutions have been shown to remove radioactivity from tissue[3] and silver grains from images[4]. Several substances have been shown to cause chemical fogging[5], but a protective film between tissue and emulsion is considered to prevent such artefacts. The observations reported here indicate that stains may be involved in the formation of artefacts when a thin nitrocellulose film is used and that artefacts as well as bleaching of stains may be prevented by embedding sections in a hydrophobic layer.

Strain-induced artefacts. Slides with 8μ thick sections of non-radioactive rabbit uterus were deparaffinized and covered with a thin or thick coat of nitrocellulose. Kodak *NTB*3 emulsion was applied over these unstained sections, the slides sealed in light-tight boxes and processed after 24 hr. in the refrigerator (Fig. 1 ; Table 1, slides 1 and 2). Slide 1 showed several aggregates and the grain count over tissue was twice the background count $(P < 0\cdot001)$, whereas slide 2 showed no aggregates and the grain count over tissue was not significantly different from background. Among slides with a thin nitrocellulose coat, appreciably fewer aggregates were found on those that were dried flat after dipping in nitrocellulose than on slides which were dried vertically.

The thin coat was applied by two dips in 1 per cent nitrocellulose, the slide being dried for 15 min. after the first dip and overnight after the second. The film which resulted was about 0·3μ thick and the emulsion formed a layer varying in thickness from 3 to 10μ. The thick coat was obtained by pipetting 1·5 ml. of 2 per cent nitrocellulose on the slide and drying in a slow stream of air for about 18 hr. The sections became embedded in a 9μ thick layer of nitrocellulose and the emulsion applied on its even surface formed a uniform layer about 3μ in thickness.

It has been suggested[2,4] that emulsion layers of uneven thickness may become reduced due to physical strains during drying or processing. Evidence confirming this view was obtained here when clean slides, slides with coverslips cemented on them and slides with depressions (5, 8, 10 and 15μ deep) ground on them were coated and processed as in the case of slide 1. Aggregates and grains were found at the edges of coverslips and depressions. It may be mentioned here that such strain-induced artefacts occur with 5μ or thicker sections ; they are less common or absent with thinner sections. Tissue sections with few spaces or small ones (less than about 30μ across), such as liver and spleen sections, also do not produce many artefacts.

Chemically induced artefacts. In order to determine whether stains could reduce the emulsion when they were separated from it by a thin nitrocellulose film, a drop each of Mayer's hemalum and 1 per cent eosin were dried on a slide, the slide was coated with

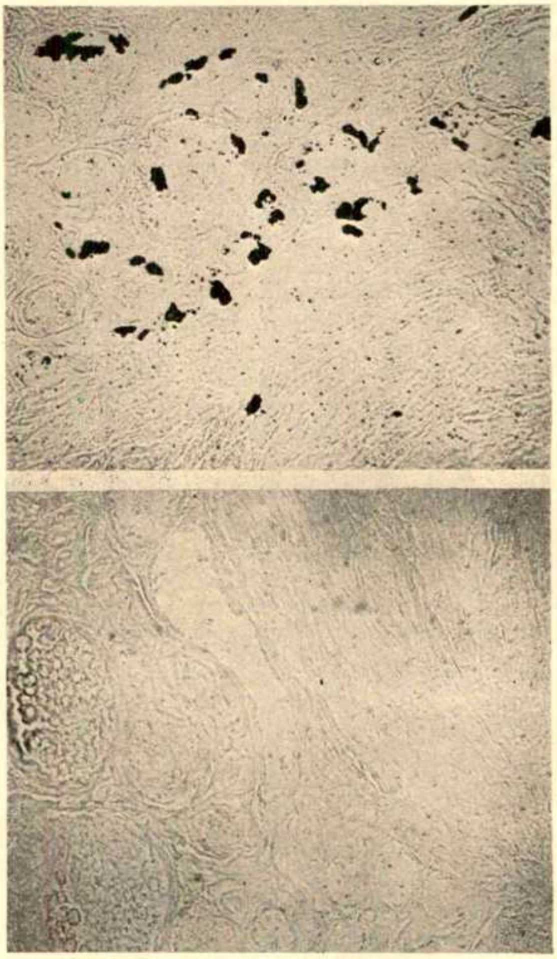

Fig. 1. Non-radioactive unstained section of rabbit uterus covered with a thin nitrocellulose coat (above) showing strain-induced aggregates and grains. Similar section embedded in a thick nitrocellulose coat (below) showing absence of aggregates ; grains over this section appear as out of focus images due to the thick nitrocellulose coat. (× 300)

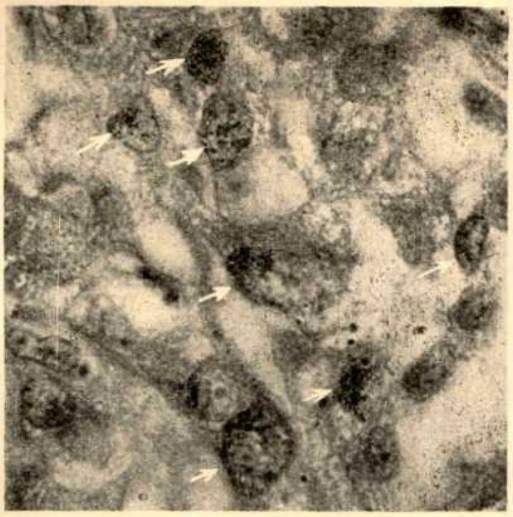

Fig. 2. Grain clumps (arrows) over non-radioactive nuclei (slide 4, Table 1). (× 1,000)

nitrocellulose and emulsion and processed. The grain counts over hemalum, eosin and background were $24 \pm 6{\cdot}1$, $12{\cdot}3 \pm 0{\cdot}86$ and $7{\cdot}2 \pm 0{\cdot}75$ respectively. Counts around the hemalum spot were 1·5–2 times background count, indicating some lateral diffusion of the reaction. When non-radioactive sections stained in hemalum were treated similarly, counts over tissue and background were 18·1 and 7·4 respectively (Table 1). The mean number of aggregates was 63·4 and the largest of them was 262μ. Corresponding results with sections stained in eosin were 10·8 and 7·1 grains over tissue and background, mean number of aggregates 22·2 and the largest of them measuring 210μ. All grain counts are significantly above background ($P < 0{\cdot}001$, except slide 4, where P is 0·03). The difference between aggregate counts over unstained sections and those stained with eosin is also significant ($P < 0{\cdot}02$). Aggregates on these slides were not confined to tissue spaces and edges as the strain-induced ones were. Slides on which sections were stained for 5, 10 and 15 min. in hemalum showed increasing grain count over tissue with longer staining time (5·9 : 13·3 : 14·9, $P < 0{\cdot}01$). Similar sections counterstained with eosin for 10 min. also showed an increase (8·7 : 10·8 : 15·3, $P < 0{\cdot}01$). The increase of grain count with longer staining time was abolished by a thick coat of nitrocellulose. These experiments show that stains, either directly or from tissues, may reduce the emulsion in spite of a thin nitrocellulose film.

Observations such as the effect of a thick nitrocellulose coat in reducing artefacts, and association of aggregates and grains with bleached areas of stained sections, indicated that the photographic developer and fixer (Kodak *D*19 and 'Acid Fixer'), diffused across the thin nitrocellulose film, reacted with the stains on sections and as a result stains were bleached and the emulsion reduced. Slides processed in a less alkaline *D*19 (made up with 3 gm. of sodium carbonate instead of 48 gm./l.) and 5 per cent sodium thiosulphate showed a grain count over tissue similar to background count and bleaching of stains was almost eliminated. Thus, these chemically induced artefacts seem to be the result of interaction between the stains and *D*19 and 'Acid Fixer'.

One other observation of grains appears worth recording. Slides 3 and 4 (Table 1) showed several nuclei over which grains occurred in clumps (Fig. 2). The mean of grain counts over 20 nuclei on slide 3 was 15·75. These artefacts are indistinguishable from autoradiograms of nuclei labelled with tritiated thymidine.

Protective coating. Systematic work[6-9] on protective films has tested a wide variety of substances. None of them seems to give complete protection and yet is satisfactory in other respects[10]. More recently 'Plexiglas' solution and acrylic membranes have been tried[11,12]. 'Harleco Synthetic Resin' (HSR), the routine mounting medium for histological preparations in this laboratory, was found to be a satisfactory protective coating. The sections may be coated after staining, dehydration and clearing in xylol in the following manner. Each slide is removed from xylol, the under surface and edges wiped dry and placed on a previously levelled metal platform. A volume of 2 per cent HSR in xylol that will produce a layer as thick as the sections is pipetted on the surface before the sections become dry. The linear relation between volume of 2 per cent HSR and final thickness of dry coat is obtained by prior calibration. When all slides are ready a 'Plexiglas' cover is placed over the platform and a stream of air drawn over the slides through an outlet on top of the cover using a squirrel cage blower. The slides are dried overnight and may then be coated with emulsion. The sections become embedded in the HSR layer, which presents a smooth and even surface to which emulsion will adhere.

Sections stained with toluidine blue, phosphotungstic hæmatoxylin and with two triple stains (Heidenhain's azan and by the method of Himes and Moriber[13]) were fully protected by HSR. The resin does not seem to reduce the emulsion by itself; after exposure of emulsion to the resin for 3 weeks, grain counts were not significantly different from background. HSR has excellent optical qualities[14] and is readily available (Hartman Leddon Co., Philadelphia). Since sections are embedded in HSR by this method, they never become dry during the entire process. Solvents like xylol cannot be used in permanent mounting of these autoradiograms; but the slides may be mounted in 4 per cent polyvinyl alcohol directly after photographic processing, thereby eliminating the dehydration and clearing used as a rule.

I am grateful to Dr. J. D. Ebert and Dr. B. G. Böving for their advice. I wish to thank Mr. W. H. Duncan for his suggestions concerning histological procedures.

COSMOLOGY

Dirac's Cosmology and Mach's Principle

THE dimensionless gravitational coupling constant

$$\frac{Gm_p^2}{\hbar c} \sim 5 \times 10^{-39} \qquad (1)$$

with m_p the mass of some elementary particle, for definiteness taken as the proton, is such a small number that its significance has long been questioned. Thus Eddington[1] considered that all the dimensionless physical constants, including this one, could be evaluated as simple mathematical expressions. Dirac[2] considered that such an odd number must be related to other numbers of similar size, characterizing the structure of the universe. However, most physicists seem to believe that a dimensionless constant, such as (1), is provided by Nature, cannot be calculated, and is not in any way related to other numbers.

Dirac noted that most physical and astrophysical dimensionless constants are of the order of magnitude of integral powers (positive and negative) of the number 10^{40}, where such numbers as $m_p/m_e \sim 1{,}800$ and $\hbar c/e^2 \sim 137$ are said to be of the order of unity, the zero power of 10^{40}. He considered unlikely the accidental correspondence of the apparently unrelated, enormous numbers, and he suggested some unknown causal connexion.

One of these large numbers is:

$$T\,\frac{m_p c}{\hbar} \sim 10^{42} \qquad (2)$$

with T the Hubble age of the universe. For an evolutionary universe, T varies with time. This suggested to Dirac that all the large numbers vary with time, with numbers of the order of $(10^{40})^n$ varying as T^n. Dirac[2] constructed a cosmology based on this idea, and Jordan[3] produced a proper relativistic theory of Dirac's cosmology.

The three principal large numbers are given by equations 1 and 2, and by the mass of the universe to its visible limits, expressed as:

$$\frac{M}{m_p} \sim 10^{80} = (10^{40})^2 \qquad (3)$$

According to Dirac's hypothesis, these three numbers should vary as the -1, 1, and 2 power of the time respectively.

It should be noted that it is necessary to assume more than a connexion between the three numbers (1), (2), and (3) to justify Dirac's hypothesis. In addition, one must assume that the apparent interconnexion between the three numbers is independent of time. This assumption could be supported by a statistical argument. If the present value of T were to be considered conceptually as a random choice from a wide range of possible values of T, the present 'choice' would have had a small *a priori* probability, and an accidental correspondence of the type exhibited by the three numbers would have been unlikely. In view of the inexactness of the interrelation between the three numbers, a very wide range of possible values of T and a small *a priori* probability must be assumed if Dirac's hypothesis is to receive support from this type of argument.

It will be shown that, with the assumption of an evolutionary universe, T is not permitted to take one of an enormous range of values, but is somewhat limited by the biological requirements to be met during the epoch of man.

The first of these requirements is that the universe, hence galaxy, shall have aged sufficiently for there to exist elements other than hydrogen. It is well known that carbon is required to make physicists.

It is known that the galaxy was formed initially from hydrogen only. Hence, the minimum time for the start of the epoch of man is set by the age of the shortest-lived stars, for elements, other than hydrogen, are formed in the interior, and distributed at the death, of the star.

An upper limit for the epoch of man is set by the requirement that he has a hospitable home in the form of a planet circling a luminous star. This time is set by the maximum age of a star capable of producing energy by nuclear reactions. For stars less massive, gravitational contraction is halted by the onset of electron degeneracy pressure, before central temperatures rise high enough for the onset of nuclear reactions. The mass of the longest-lived stars can be computed assuming that electron degeneracy occurs at the nuclear reaction temperature. This gives for the lower bound on M_s, the mass of the star:

$$\frac{M_s}{m_p} \sim 10^{-3}\left(\frac{\hbar c}{Gm_p^2}\right)^{3/2} \qquad (4)$$

where m_p is again the proton mass. According to the above definition of order of magnitude, 10^{-3} is to be regarded as equivalent to unity and this number is of the order of magnitude of $(10^{40})^{3/2}$.

The life-span of a star of this mass can be calculated, assuming that the emission and opacity are determined by free–free transitions (the bremsstrahlung radiation and absorption process). This lifetime is:

$$T_{\text{max.}} \sim \left(\frac{m_p}{m}\right)^{5/2}\left(\frac{e^2}{\hbar c}\right)^3\left(\frac{Gm_p^2}{\hbar c}\right)^{-1}\frac{\hbar}{m_p c^2} \qquad (5)$$

after dropping numerical factors, where m is the electron mass. Dropping the 'unity factors', this becomes:

$$\frac{m_p c^2}{\hbar}\,T_{\text{max.}} \sim \left(\frac{Gm_p^2}{\hbar c}\right)^{-1} \qquad (6)$$

in agreement with equations (1) and (2). In similar fashion, T_{min}, as determined by requirements for stellar stability, is of the same order of magnitude. Thus, contrary to our original supposition, T is not a 'random choice' from a wide range of possible choices, but is limited by the criteria for the existence of physicists.

Two problems remain. Why is the gravitational coupling constant so small? Why does the square root of the number given by equation (3) agree with the reciprocal of (1)? Both of these questions are answered by introducing Mach's Principle. According to the interpretation of Mach's Principle sometimes made[4-6], the gravitational coupling constant is not fixed but is determined by the mass distribution of the universe in such a way that:

$$\frac{GM}{c^3 T} \sim 1 \qquad (7)$$

Combining equations (7) and (6) gives the expression obtained by combining equations (1) and (3)

The reason for the smallness of the gravitational coupling constant is the enormous amount of matter in the universe This may not be a very satisfactory answer, and it cannot be completely satisfactory until the problem of mass creation is understood

The statistical support for Dirac's cosmology is found to be missing However, the existence of physicists now and the assumption of the validity of Mach's Principle are sufficient to demand that the order-of-magnitude relations between the three numbers, given by equations (1), (2) and (3), be satisfied

[6] Brans, C, and Dicke, R H, *Phys Rev*, **124**, No 3 (1961)

Dicke discusses the three cosmological numbers (1) which determines the gravitational constant, (2) which determines the Hubble age of the universe, and (3) the number of particles in the universe They are related in that (1) is roughly the reciprocal of (2) and (3) is roughly the square of (2) I assumed that these relations correspond to something fundamental in Nature With an evolutionary universe (2) varies with time, and then (1) and (3) would also have to vary with time

Dicke considers that there is a fundamental relation between (1) and (3), following from Mach's Principle, but that (2) is independent, so that (1) and (3) may be constant while (2) varies with time He then shows that (2) would have to have roughly its present value when habitable planets exist On this assumption habitable planets could exist only for a limited period of time With my assumption they could exist indefinitely in the future and life need never end

There is no decisive argument for deciding between these assumptions I prefer the one that allows the possibility of endless life One may hope that some day the question will be decided by direct observation One would have to measure (1) to an accuracy of 1 in 10^{10} and then repeat the measurement after a few years and see whether the result has altered

SPACE SCIENCE

Direct Measurement of Interplanetary Dust Particles in the Vicinity of Earth

Additional knowledge about interplanetary dust particles has been obtained from the direct measurements made with rockets, satellites, and space probes The results obtained with the microphone type of dust particle sensor carried by the U S satellites, *Explorer I* (1958 Alpha) and *Vanguard III* (1959 Eta), the U S space probe, *Pioneer I*, and the Soviet vehicles, *Sputnik III* (1958 Delta 2), Space Rockets I and II, and the Interplanetary Station (1959 Theta), have already been reported In addition, a definitive set of data has recently been obtained with the U S satellite, *Explorer VIII* (1960 Xi) A series of corrections has been completed which allows our results from a series of seven successful high-altitude rockets instrumented at Oklahoma State University to be used in quantitative discussions of interplanetary dust particles We would like to present the preliminary results (including a new and very interesting curve for the mass distribution and spatial density) from an analysis of the available direct measurements of interplanetary dust particles

The best calibrations of the microphone system that are at present possible are performed with particles ranging from large glass beads elastically impacting at low speeds to small iron spheres inelastically impacting at speeds up to approximately 10 km sec^{-1} Such calibrations indicate that the microphone system is sensitive to a quantity that is closely related to the momentum of an impacting dust particle An average velocity, relative to a satellite, of 30 km sec^{-1} has been assigned to the dust particles in order that the results may be used in a determination of the mass distribution of the interplanetary dust particles

The three datum points obtained with *Explorer VIII* are plotted (together with those from *Vanguard III*, *Explorer I* and the series of rockets) as the distribution curve shown in Fig 1 The equation of a straight line that approximately fits the datum points is

$$\log I = -17\ 0 - 1\ 70 \log m$$

where I is the influx-rate of dust particles and m is the particle mass holding approximately for m in the range 10^{-10} gm $\lesssim m \lesssim 10^{-6}$ gm The data from *Vanguard III*, *Explorer I* and the rockets fit remarkably well on the curve defined by the data from *Explorer VIII* In fact, all other available direct measurements also can be made to look fairly reasonable when plotted as in Fig 1 if proper allowances are made for the type of experiment, the confidence that can be placed in any particular measurement, the shielding effect of Earth, and the actual fluctuations in the spatial density that have been observed with *Explorer I*, *Vanguard III*, and *Explorer VIII*

The curves obtained from an extrapolation of the tabulation by Watson[1] and from the extrapolated tabulation by Whipple[2] of results from meteor observations are shown as reference curves in Fig 1 Both the extrapolated curves follow the constant mass per unit visual magnitude relationship common to discussions of results from meteor observations and roughly serve as the limits of uncertainty encountered in placing such results on a mass distribution curve This uncertainty arises because of the uncertainty in relating particle mass to photographic, visual, or radar magnitude, and the uncertainty in assigning a mass density of meteoroidal particles

Either of the extrapolated curves can be forced to pass through any one of the given direct measurements datum points by adjusting the mass to magnitude relationships and the mass density for meteoroidal particles The three datum points obtained with *Explorer VIII* define a slope for a limited portion of the distribution curve in addition to defining the influx-rates for dust particles in three different ranges of particle mass, showing that the curve determined by direct measurements departs significantly from the extrapolated curves

Caution must be exercised in extrapolating the new distribution curve out of the range of particle mass for which direct measurements have actually been

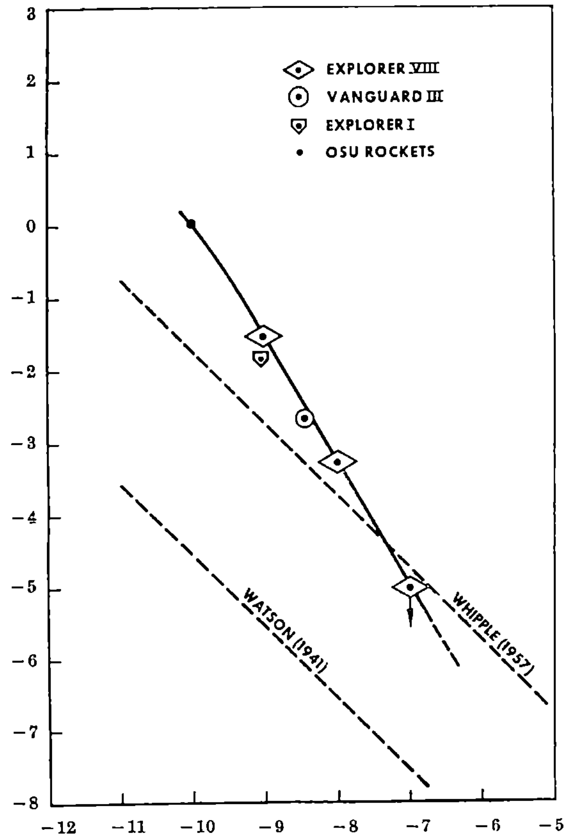

Fig 1 Distribution curve for interplanetary dust particles in the vicinity of Earth

obtained A considerable change in the shape of the distribution curve is bound to occur between the direct-measurements range of particle size and the range of particle size where the radiation pressure control becomes dominant unless there is a most prolific source of very small dust particles somewhere near or inside the orbit of Earth The new distribution curve can be joined smoothly to the extrapolated curve labelled "Watson" at a size of particle smaller than the faintest radar meteors, but junction with the curve labelled "Whipple" is rather difficult

An interesting consequence of the new distribution curve is that the daily influx-rate of interplanetary dust is approximately 10^4 tons a day on Earth, meaning that dust particles in the direct-measurements range of particle size dominate the accretion process The meaning of the new distribution curve with regard to theories of the zodiacal light and observations of atmospheric aerosols bears further investigation

The question whether the direct-measurements results show a dependence on altitude of the spatial density of dust particles has not been resolvable, on the basis of results obtained with the microphone type of impact detector, prior to obtaining the results of *Explorer VIII* The reason for this difficulty was that the rocket measurements were of higher sensitivity and at lower altitudes while the reliable satellite measurements were generally of lower sensitivity and at higher altitudes The satellite measurement at high sensitivity and at a large geocentric distance made by *Pioneer I* extended over only a short sampling interval and may not be of much use in establishing a model average distribution Any one of several interpretations could be given to the available direct measurements, depending on the choice of a model distribution to which they were compared

By assuming that the extrapolated curve labelled "Whipple" represented the true distribution, Whipple[3] has deduced that the direct measurements have confirmed the existence of a geocentric "dust belt" If the empirical curve defined by the data from *Explorer VIII* is used as a basis for an analysis of other direct measurements results, then no discernible dependence on altitude of the spatial density of dust particles exists The conjectural geocentric concentration of dust particles under discussion here should not be confused with concentrations of dust-particles possibly suspended in the atmosphere of Earth at and slightly above the temperature inversion layer at about 80 km altitude

In conclusion, it should be emphasized that while the data at present available show no evidence for the existence of an appreciable geocentric concentration of dust particles, the data are really not of such a nature that they can be used in conclusively settling the question If such a concentration does exist, then it certainly has not been convincingly measured by rockets and satellites The direct measurements are quite useful in determining a new model of the average dust distribution, with the direct measurements results showing remarkable self-consistency when displayed as in Fig 1

ASTRONOMY

Exact Determination of the Lunar Mass by means of Selenoid Satellites

As is well known, the astronomical determination of the mass of the Moon has so far been accomplished by methods based on the observation of the terrestrial nutation of the motion of the centre of the Earth around the centre of mass of the Earth–Moon system, and from the perturbation of the asteroid Eros

The numerical value 0 01230 times the terrestrial mass is known to four significant figures, with an accuracy of about 4 parts in a thousand It has been suggested[1,2] that this accuracy can be improved by observation of the motion of what we have called a 'selenoid satellite', that is, a satellite placed in the general vicinity of one of the sextile libration points of the Earth–Moon system The reasons for believing that an improved accuracy would result by means of such a method are based on the fact that, in the first place, a prolonged time of observation would, in this case, be available, secondly, that the motion of such a body would be accurately predictable

More specifically, the motion of a selenoid satellite could be qualitatively described[1,2] as a superposition of what we might call free and forced oscillations The free oscillations would be those which the selenoid would perform if the Earth–Moon system were isolated in space If the relative orbits of the Earth and the

Moon were exactly circular, the period of these oscillations would be respectively of 28 54 and 91 35 sidereal days. Owing to the effects of non-linear terms and eccentricity of the Earth–Moon orbits, additional periodic terms having as period all possible linear combinations of the above periods as well as of the period of the unperturbed Earth–Moon system will make their appearance The forced oscillations will be due mainly to the action of the Sun, which will directly influence the orbiting satellites as well as the remaining components of the Earth–Moon system The most conspicuous of the above oscillations will presumably be the free ones as well as those having periods equal respectively to the sum and difference of one year and the above free periods

The proposed method of determination of the lunar mass is based on establishing, by means of a periodogram analysis of the libratory motion executed by the selenoid satellite, its free periods The latter depend solely on the ratio of the masses of the Earth and the Moon which can thus be directly calculated The determination of such periods could be accomplished with considerable accuracy on the basis of straightforward astronomical observation of the position of the selenoid satellite on the celestial sphere When the above method was originally suggested, the use of artificial selenoid satellites (in the form of large inflated balloons) was contemplated Quite recently, however, K Kordylewski, of the Cracow Observatory, has reported the discovery of two (cloud-like) natural selenoid satellites orbiting in the vicinity of the trailing libration centre of the lunar orbit[3] On the basis of the data communicated by Kordylewski, the amplitude of the libration of the two bodies can be estimated to be of the order of a few degrees, which appears adequate for a determination of the periods as described above It is hoped that a sufficient number of sufficiently accurate data will be available in the near future, thus permitting application of the proposed method It should be noted that a complete description of the motion of the selenoid satellites is redundant for the purpose discussed here, since the information required can be extracted from the knowledge of the dependence on time of any appropriate co-ordinate

PHYSICS

Radioactivity in Rainfall during September 1961 following the Russian Nuclear-Weapons Tests of September 1961

The collection and analysis of rainwater are a part of the environmental survey programme of this Laboratory Simple analysis of the total β-activity, consisting of evaporation and counting the residue, using anti-coincidence low-level techniques, has been carried out over the past two years and specific isotopic analysis has been performed when this was of particular interest, as at the present time

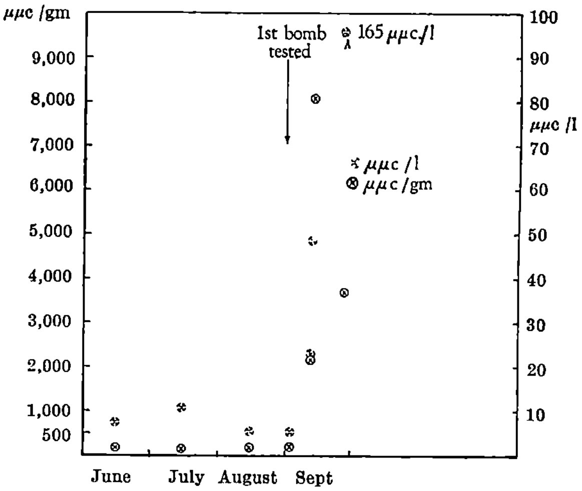

Fig 1 Total β-activity of rainwater and rainwater residue from June to September 31

From the analyses for total β-activity it is evident that the residue from rain falling after September 2, 1961, that is, following the commencement of the Russian nuclear tests, had an activity which was of a distinctly higher order (up to 8,000 μμc /gm) than that of previous months rainfall (about 160 μμc / gm) The activity of the rainwater in this period was correspondingly greater (48 4 μμc /l) compared with previous months (about 5 1 μμc /l).

The results of these and subsequent samples are presented in Table 1 The build-up of activity in the rain can be seen from a graphical interpretation of these results (Fig 1)

Table 1 TOTAL β-ACTIVITY OF RAINWATER AND RAINWATER RESIDUE

Date of sample collection	Date of sample analysis	Rainwater* (μμc /l)	Rainwater residue* (μμc /gm)
1/8/61–31/8/61	12/ 9/61	5 1	157
2/9/61– 4/9/61	5/ 9/61	3 4	188
12/9/61–13/9/61	20/ 9/61	22 7	2,160
13/9/61–14/9/61	18/ 9/61	48 4	8,050
27/9/61–28/9/61	3/10/61	165 0	2,360

* Activity at date of analysis

In view of the complex nature of the uptake of solid matter during and after cloud formation, both activities per litre of rainwater and per gram of residue have been given The uncertainty in both these figures is conservatively estimated at ± 20 per cent, so that the increases after September 12 are highly significant

Specific Isotopic Analysis To confirm that the excess activity was due to fission products, specific isotopic analysis was carried out for iodine-131 This isotope was chosen partly because of its biological importance, but it was also convenient as a tracer because of its characteristic 0 36-MeV. γ-ray The half-life of 8·05 days was sufficiently long to permit precise measurement but not long enough to permit iodine contamination from previous tests to cause confusion.

Chemical separation of iodine was made and the resulting samples were counted for β-activity using anti-coincidence methods The activity was attributed

Table 2 IODINE-131 IN RAINWATER (ACTIVITY)

Date of sample collection	Date of sample analysis	Activity at date of analysis μμc /l of iodine-131
13/9/61–14/9/61	14/9/61	9 8
14/9/61–18/9/61	18/9/61	95 5 82 0*
27/9/61	28/9/61	14 2

* By γ-ray spectra analysis

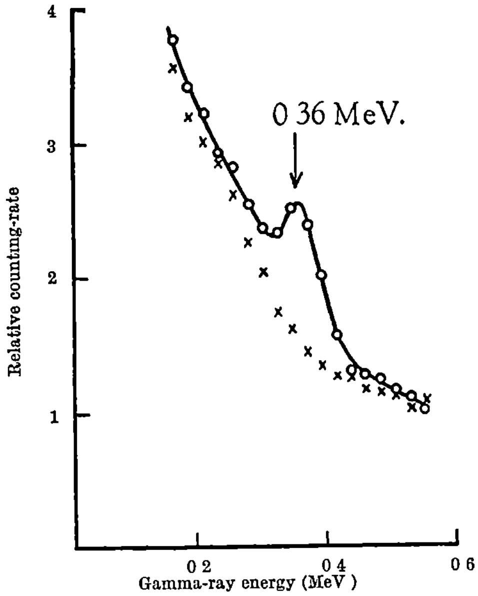

Fig 2 Gamma spectrum of iodine-131 in rainfall O, Source, ×, background

to iodine-131 in view of the comparatively short half-lives of the other iodine fission products A confirmatory measurement on one of the samples was made by γ-ray spectrometer analysis for iodine-131 Good agreement was obtained, as can be seen in Table 2 The spectrum obtained is shown in Fig 2

The confirmatory test of the γ-ray spectrometer on the second sample yielded a result of 82 μμc /l of iodine-131 compared with 95 5 μμc /l by β-analysis

Although these preliminary results indicate clearly the onset of the Russian testing programme, it is impossible at this stage to attempt a more detailed correlation with individual tests

I would like to thank Mr R A Pope for measuring the γ-ray spectra, and the staff of the Radiological Protection Unit for the preparation and analysis of samples I would like to express my special thanks to Dr S E Hunt for his helpful advice and comments Thanks are due also to Dr T E Allibone, director of the Laboratory, for permission to publish this communication

Nuclear Spin of Protoactinium-231 from Hyperfine Splitting

The nuclear spin of protoactinium was first determined by Schuler and Gollnow in 1934[1] They examined the spectrum of protoactinium-231 in the region 4300–5600 Å and obtained the nuclear spin $I = \frac{3}{2}$ from hyperfine splitting

More recently the nuclear spin of protoactinium-233 has been determined[2] from paramagnetic resonance, and the nuclear spin of tetravalent protoactinium-231 from an investigation of paramagnetic resonance and hyperfine structure[3] Both authors obtain $I = \frac{3}{2}$

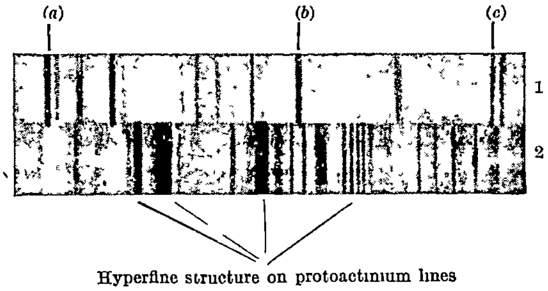

Fig 1 Protoactinium-231 spectrum with thorium comparison spectrum 1, Thorium comparison spectrum, 2, protoactinium spectrum, *a*, thorium, 5869 847 Å , *b*, thorium, 5874 981 Å , *c*, thorium, 5878 922 Å

So far, however, the work of Schuler and Gollnow has not been confirmed

The atomic emission spectrum of protoactinium-231 was recently photographed in the region 4000–9000 Å using the 21-ft grating spectrograph at Harwell, and also recorded in the region 0 8–2 5μ The light source was an electrodeless discharge tube containing about 3 mgm of protoactinium iodide and excited by microwaves The spectrum shows pronounced hyperfine structure, the majority of lines being split into four components This confirms the value $I = \frac{3}{2}$ obtained by previous workers

Rotational Analysis of $^{65}Cu^{35}Cl$ Bands

Although many extensive band systems are known for the CuCl molecule[1], our knowledge of their rotational structure has been meagre Apart from being heavy, natural cuprous chloride is a mixture of four isotopic species with not very different relative abundances Very high dispersion and resolution are therefore needed to resolve, even partially, the rotational structure of the bands

With the availability of compounds containing separated copper and chlorine isotopes, it has become possible to prepare copper chloride with any desired copper and chlorine isotopes Milligram quantities of $^{65}Cu^{35}Cl_2$ have been thus prepared and the spectrum of $^{65}Cu^{35}Cl$ excited in an electrodeless discharge tube by a 2 450 mc /sec Raytheon microwave oscillator[2] All the known band systems of cuprous chloride were obtained with high intensity The bands were photographed mostly in the fifth order of the Argonne National Laboratory 30-ft concave grating spectrograph (dispersion 0 3 Å /mm) Bands for which rotational analysis has been done are given in Table 1 Spectroscopic data obtained from the present work are given in Table 2 All values in this table, except those of r_e, are in cm $^{-1}$ units

Table 1

X	0	415.29	1.58	—	0·1764	10.0	—	1.3	2.050		

The rotational analysis indicates that the upper states of the five systems are either $^1\Pi$, $^1\Sigma$, etc., as shown in Table 1 or states which 'behave' like these. The Λ-type doubling in the F state is negligible, whereas that in the D and B states is large. This is apparently due to the circumstance that whereas there is no perturbing state near the F level, the levels D and B have each a perturbing state nearby.

In a recent note, Lagerqvist *et al.*[3] have given the results of their rotational analysis of the (1,0), (0,0) and (0,1) bands of the B–X system and the (1,0) band of the C–X system of $^{63}Cu^{35}Cl$ recorded in absorption. The rotational constants of $^{63}Cu^{35}Cl$ calculated from the present $^{65}Cu^{35}Cl$ data are in excellent agreement with those given by them.

Electron Paramagnetic Resonance and Antiferromagnetism in $LaCrO_3$

The presence of antiferromagnetic ordering in $LaCrO_3$ has been verified before by both neutron diffraction[1] and static magnetic susceptibility[2] techniques. In the former case, a Néel temperature of approximately 320° K is reported, while the susceptibility results indicate $T_n \approx 295°$ K. Above T_n, $LaCrO_3$ is paramagnetic and hence amenable to investigation by standard electron paramagnetic resonance techniques. We have carried out the experimental resonance investigations over the temperature-range 200–450° K.

The powder was prepared by heating reagent grade Cr_2O_3 and La_2O_3 at 1,600° C for 2 hr. Our X-ray diffraction results indicate a typical perovskite with small distortions from cubic symmetry. Assuming a cubic structure, we find the lattice parameter to be 3.870 Å in reasonable agreement with the value 3.874 Å published in ref. 3.

The pertinent features of our results are summarized in the figures. All data were obtained at 9.1 kMc/s using a Varian V–4500 electron paramagnetic resonance spectrometer with d.c. magnetic field varied continuously from 0 to 10,000 gauss. The resonances were singly peaked, with g values equal to 1.98, at all observable temperatures.

Our results are consistent with previous resonance investigation of similar compounds[4]. In the antiferromagnetic state anisotropy and exchange fields effectively 'drive' the resonance from the region of observation[5]. Line-widths exhibit the behaviour predicted by the calculations in ref. 6. With antiferromagnetic ordering each Cr^{3+} ion is indirectly coupled to the six nearest similar ions with spin orientation opposite to that of the central ion. Since the spins 'lock' into this configuration, the time-averages of the dipolar fields at a particular spin site approach the instantaneous value. Hence line-broadening results. Extinction of resonance below the transition appears to rule out impurities as a major contributor to line-width.

In the paramagnetic region, it is expected that peak intensities will be proportional to the magnetization and hence the susceptibility[7]. However, it has been argued that peak intensity should depend on both magnetic susceptibility and the existence of some residual short-range order close to, and above, T_n (ref. 8). The transitions observed here are relatively abrupt when compared with similar results for other compounds[8]. This is interpreted as indicating a minimization of short-range order effects above and close to T_n. Hence from the maximum in relative intensity we obtain $T_n \approx 295°$ K. Our numerical agreement with the susceptibility results is, no doubt, fortuitous. The two results are, however, taken to be in approximate agreement. In any event, the present results differ appreciably from that of the neutron diffraction experiments. In this respect it is perhaps significant to note that Jonker[2] prepared his sample in a manner somewhat similar to ours, using the same compounds as starting materials. On the other hand, Koehler and Wollan[1] used as their starting

GEOLOGY

Potassium-Argon Ages at Broken Hill, Australia

WE have obtained three results which contribute something to an understanding of the more recent events in the Broken Hill district of New South Wales. Field evidence[1,2] indicates that the main lead lodes lie conformably with gneisses of the Willyama Series, thought to have been formed from sediments of older Precambrian age These have been strongly folded, the metamorphism and folding having taken place before deposition of the younger Torrowangee Series, which is regarded[3] as equivalent to the Adelaide System of Upper Precambrian age At some subsequent time, possibly in the early Palæozoic, greenschist facies assemblages were developed (White, A. J R , personal communication) in the Torrowangee Series, suggesting that temperatures were reached adequate for the loss of a considerable proportion of any argon (if not all) accumulated up to that time[4]. Although there is comparatively little evidence for this heating (Carruthers, D S , personal communication) in the earlier Willyama rocks, it is inconceivable that they can have been completely unaffected This inference is supported by our results.

The Broken Hill samples analysed were

GA 113	Upper granitic gneiss (Formation No 13), New Broken Hill Consolidated, Ltd	Age 504 m y
GA 114	Sillimanite biotite garnet gneiss (Formation No 4), No 21 level, Zinc Corporation, Ltd	Age 526 m y

These results are to be compared with the age determined on a transgressive-type granite (*GA* 212) from Encounter Bay, in the southern part of the Adelaide Geosyncline The date obtained here, 457 m y , can be regarded as being related to the more recent events in the Adelaide Geosyncline, thus constituting a possible upper limit to the time of any movement of the Torrowangee at Broken Hill Thus the Cambrian ages obtained for the undoubtedly older gneisses suggest that the event affecting the Torrowangee happened between 500 and, say, 460 m y. ago, with the implication that the effect on the older Willyama rocks may not have been sufficiently intense to cause total loss of argon. There is inadequate evidence to relate these results with the two 'model ages' derived from lead isotope measurements by Russell *et al* [5], of 1,600 m y for the conformable leads, and "less than 1,000 m y " for the event causing the formation of the transgressive Thackaringa-type deposits Further measurements are in progress, and more complete details of these experiments are to be published elsewhere

METALLURGY

Difference between High- and Low-Stress Fatigue

RECENT papers by Porter and Levy[1] and Benham and Ford[2] have suggested that the conventional *S/N* curve is composed of two separate curves, a discontinuity occurring at some particular stress-level. The former authors concluded from a large number of rotating bending tests on copper that the discontinuity occurred at about ± 21,500 lb /sq in., for lower stresses fatigue cracks originating in slip bands; for higher stresses cracks developing from L-shaped nuclei Kemsley[3] also found that with copper specimens tested at ± 15,000 lb /sq in (giving fracture after long endurances) cracks formed in slip bands and were transcrystalline, while at ± 25,000 lb /sq in. (giving fracture with low endurances) slip bands were virtually absent from the specimen and cracks appeared to be intercrystalline Benham and Ford[2], who tested mild steel in direct stress, found for large stress amplitudes that the specimen gauge-length extended permanently each cycle and a 'necked-out' fracture resulted They termed this phenomenon 'cyclic creep' and such failures occurred while the stresses corresponded to the upper portion of the composite *S/N* diagram For stresses in the lower portion of the *S/N* diagram typical fatigue fractures occurred and they suggested that, if the fatigue mechanism could be suppressed as the cyclic stress decreased, the upper curve might flatten out to a 'cyclic creep limit'

Low-endurance fatigue tests have been carried out by many workers, the usual procedure being to apply strain cycles rather than stress cycles of constant amplitude, the work of Coffin[4] is typical Coffin suggested the results of such tests could be represented by the equation

$$N^{\frac{1}{2}} \varepsilon_p = C$$

(where N = number of cycles to failure, ε_p = cyclic-plastic strain amplitude and C = material constant). The endurances over which this relationship applies vary with material Coffin found for copper it was about 10^2 cycles, for aluminium about 10^5 cycles

On the other hand, when the cyclic stresses are in the vicinity of the fatigue limit, no relationship exists between the width of the hysteresis loop and life of specimen. For such tests, metallographic examination of the specimen surface shows, in general, that slip bands form early in the test from which micro-cracks eventually develop Indeed, both Hempel[5] and Wadsworth[6] have observed that, with mild steel, cracks may form in slip bands at stresses just below the fatigue limit Crack initiation may thus be considered as a consequence of surface roughening within broad slip bands[7,8]

Holden[9] has proposed a mechanism of failure, distinct from that responsible for surface crack initiation, occurring when the material is subjected to cyclic strains such as those occurring in the material ahead of a growing fatigue crack From examination, by means of an X-ray micro-beam technique, of the fractured faces of a material through which a crack had grown and of plain specimens subjected to large cyclic-plastic strains, he found for mild steel and aluminium the structure consisted of well-defined sub-grains. The sub-grains became progressively more misorientated as the test proceeded and he suggested that cracks could form in the sub-grain boundaries

Sub-grains have been observed metallographically on the surface of fatigue specimens by, for example, Forsyth[10] and Jacquet[11], although, in their case, the sub-grain structure did not contribute to failure presumably because the cyclic stress was insufficient to misorientate the sub-grains through sufficiently large angles, and failure arose from surface roughening as mentioned above

It could thus be argued that, when plain specimens are subjected to such nominal stresses that failure occurs in a small number of cycles, failure is due to the formation of sub-grains in the bulk of the specimen and cracks forming in the sub-grain boundaries In such cases the life of the specimen is related to the plastic strain amplitude, indeed, Holden suggested that the random movement of dislocations into arrays leads to a relationship of the type suggested by Coffin. As the nominal stress amplitude is reduced a stress-level will be reached at which either the sub-grain structure does not form or, if sub-grains do form, they are unable to misorientate through sufficiently large angles to cause cracking This stress-level may be considered as the 'true plain fatigue limit' although, of course, its value is much higher than the conventional plain fatigue limit For a plain specimen to fail at lower stress-levels it is necessary for surface roughening phenomena to produce surface grooves or cracks. The sub-grain structure will then form at the groove root due to the local strain concentration and the crack may grow across the specimen Whether or not cracks of macroscopic dimensions formed in notched specimens grow has been discussed by me[12]. It is not unreasonable to suppose that the behaviour of micro-cracks in surface grooves will be similar. Thus, at stresses below the 'true fatigue limit' a specimen fails because surface roughening phenomena effectively turn the plain specimen into a notched one. The life and nominal cyclic-plastic strain are now no longer subject to the same relationship as that which applies when stresses are above the 'true plain fatigue limit' The cyclic stress below which the specimen will not break (the conventional plain fatigue limit) is that value of the cyclic stress which is just unable to produce surface grooves or cracks to a sufficient depth to enable them to grow

CRYSTALLOGRAPHY

Lattice Rotation at Slip Band Intersections

INTERSECTION of a slip band by an active slip band of different slip direction results in the formation of a step in the first band. Slip band intersections in magnesium oxide crystals suggested that the distortion of the intersected band was not merely a shear due to lattice translation, this was supported by the observation that subsequent widening of the intersected band (as described by Gilman and Johnston[1]) added to it a margin that followed the step This indicated that there was a change of lattice orientation at the intersection Imaging X-ray photographs of the Berg–Barrett[2,3] type confirmed the change of lattice orientation Fig 1 shows a compressed magnesium oxide crystal, afterwards etched to reveal dislocations; the dislocation etch-pits make the bands appear dark. Fig 2 is an X-ray image of the same crystal; the slip bands appear dark because of the reduction of primary extinction The slip band inter-

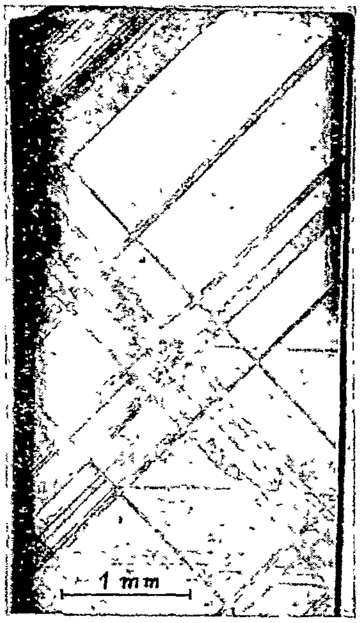

Fig 1 Etched surface of compressed magnesium oxide crystal, reflected light

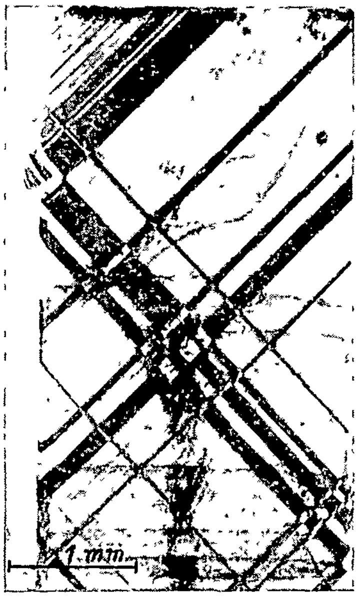

Fig 2. X-ray back reflexion image of same surface as in Fig 1, copper K_α radiation, reflexion from (210) plane

sections are white, and the reflexions from them can be found in more or less displaced positions, showing that there is a macroscopic change of orientation of the lattice at the intersections Such a change can arise in the way shown in Fig 3 Since the intersection is full of edge dislocations of both slip directions [110] and [$1\bar{1}0$], and the shear stress is the same in both slip systems, the shear strain in the active slip band may be due to slip and kinking[4,5] (= slip on the planes of the intersecting band) in the area of intersection In Fig 3 all strain in the intersection is assumed to have been the result of kinking

In Fig. 3, the parallelogram of the intersection is bounded by edge dislocations arranged in the same sense of rotation, because the dislocations of th intersecting band have arrived from outside, those of the intersected band (the kink dislocations) from inside the parallelogram Evidently, the lattice rotation due to conversion of slip into kinking at the intersection has the direction shown by X-ray asterism of the microscopic type (asterism of the macroscopic type is due to bending of the slip lamellæ[6], it is a different phenomenon) Conversion of slip to kinking is possible whenever slip bands with different slip directions intersect, it may also occur between parallel slip bands in sodium chloride[7], and it seems to be the cause of microscopic asterism generally

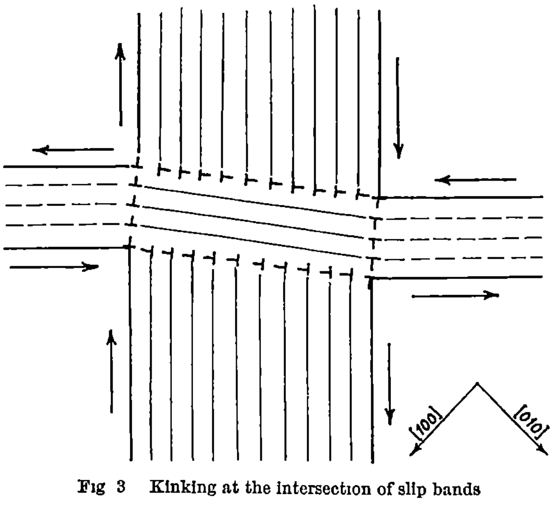

Fig 3 Kinking at the intersection of slip bands

The array of dislocations forming the low-angle boundary of the intersection is an obstacle to further slip and a possible cause of strain hardening in the post-easy-glide region Kink conversion, therefore, may perform the same task in the theory of strain hardening as Lomer–Cottrell dislocations, with the advantage of being a more general and observationally less elusive process Fig 3 indicates that it is a reversible process which may be connected with the Bauschinger effect and associated reversal phenomena Since the kink-conversion areas oppose slip in one direction more than in the opposite one, they may play a part in fatigue and extrusion phenomena[8] The stresses due to kink-conversion may lead to crack formation in several ways, explaining the observations of Stokes, Johnston and Li[9] which could scarcely be attributed to crack nucleation by reactions between individual dislocations

CHEMISTRY

Requirements of an Ice Nucleus

THE striking similarity between the crystal lattices of silver iodide and ice led Vonnegut[1] to the conclusion that the efficiency of a substance as an ice nucleator depended on the closeness of fit between the ice lattice and the lattice of the nucleating substance This view persisted for some years, but it has become increasingly apparent[2] that nucleation is not governed by lattice spacing only and that a good nucleator must also possess some other characteristic By taking into account the changes in entropy involved in growing ice on a polar substrate, Fletcher[3] has predicted that the second necessary characteristic of a good nucleator is that exactly half the water molecules comprising the layer immediately adjacent to the nucleating surface should have a proton directed towards this surface As a first approximation this requires that a uni-univalent nucleator such as silver iodide should present a surface comprised of equal numbers of positive and negative ions, thus the surface should be at its isoelectric point, and any departure from this point due to the adsorption of potential-determining ions would be expected to decrease the nucleating efficiency

In what follows we present what we believe to be the first experimental demonstration that ice nucleation is indeed a function of the surface charge of the nucleating substrate

The surface charge of silver iodide particles in contact with an aqueous solution is readily controlled by the concentration of silver ions and iodide ions in the solution[4] Therefore the freezing point of a small droplet of such a solution in contact with silver iodide particles reflects the effect of surface charge, providing that there is no interfering electrolyte effect, and that each droplet contains a uniform quantity of silver iodide To meet these requirements, monodisperse sols of constant particle size and concentration were prepared by diluting, with water, a saturated solution of silver iodide in 0 2 *M* potassium iodide A uniform deposit of sol particles was centrifuged on to glass coverslips which had previously been rendered hydrophobic by treatment in chlorsilane vapour The particle-coated slips were washed thoroughly in water, sprayed with the required solution by means of a spinning disk atomizer, transferred to a microscope cold stage, cooled at a rate of 2 deg C per min, and the freezing point of each droplet noted To avoid undue scatter the freezing point of only the droplets between 30μ and 60μ in diameter was recorded, the average number of particles per 50μ droplet being 200. In each experiment about 50 droplets were observed, and generally all the droplets froze within a range of 4 deg C

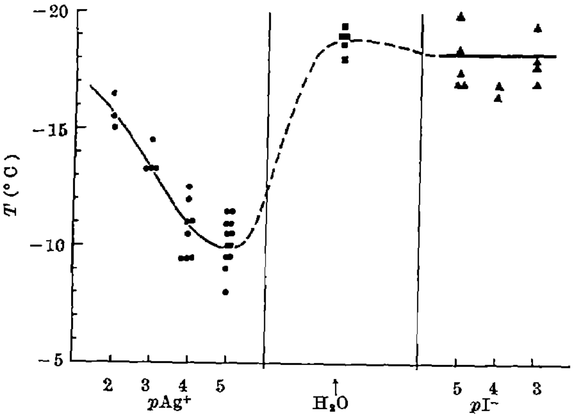

Fig 1 The variation of T with the composition of the droplets ●, Silver nitrate solutions, ▲, potassium iodide solutions, ■, distilled water

Fig 1 shows how T, the temperature at which 50 per cent of the droplets had frozen, varied with the composition of the droplets

It is apparent that, as Fletcher's theory would suggest, nucleation is most efficient in the vicinity of the isoelectric point (10^{-6} *M* silver nitrate[4]) and that quite extreme supercooling is required when the surface is charged either positively or negatively That iodide ion should be the more effective in this regard is consistent with the known tendency of silver iodide to adsorb iodide ions in preference to silver ions

These results are unaltered by the presence in all solutions of 10^{-2} *M* potassium nitrate, therefore the variations in T are not due to changing ionic strength

It is of considerable practical importance that the negative charge which silver iodide acquires in pure water is sufficient to hinder nucleation This suggests a new approach to the search for the best cloud-seeding substance—namely, that the substance should be at the isoelectric point under the conditions prevailing within a super-cooled cloud droplet

Evaluation of Boundary Layer Thickness in Electrolytic Systems from Decay of Anode Concentration Polarization

The boundary layer produced in the vicinity of a dissolving anode in an electrolytic system is maintained by a supply of ions from the electrode, which supply balances the migration away from the layer due to the combined effects of electrical transport, diffusion and convexion On interruption of current, the excess concentration of the existing boundary layer is reduced by convexion and diffusion into the bulk of the electrolyte The convexion conditions may be very complex since a natural convexion mode occurs as a result of changes in solution density in the immediate vicinity of the electrode

Two extreme limiting conditions may be established for the decay of the excess concentration in the boundary layer on current interruption First, it may be assumed that there is zero relative motion between the fluid of the layer and that of the bulk electrolyte This 'pure diffusion' extreme is analogous to the levelling of a concentration excess from a zone within a solid to the remainder of the solid. Secondly, it may be assumed that 'perfect stirring' corresponds to the decay of an excess concentration within a zone with no accompanying change in the spatial dimension of the zone, together with a continual maintenance of the bulk concentration at the outermost extremity of the zone In the 'perfect stirring' case, natural convexion is considered to contribute negligibly to the establishment of the thickness of the boundary layer, this layer being chiefly a function of externally imposed stirring conditions

Intermediate to the extreme conditions must lie 'mixed' control of collapse of the boundary layer by both stirring and natural convexion in addition to the ever-present diffusion

The concentration contour of the boundary layer may be approximated by a straight line tangent to the slope of the actual contour at the electrode ($x = 0$), thus denoting an effective boundary layer thickness at the point of intersection of this line with the bulk concentration

For any given effective boundary layer thickness δ, the concentration (strictly, activity) at $x = 0$ is given, where zero time occurs at current interruption for 'pure diffusion' as

$$\frac{C-C_b}{C_0-C_b} = \operatorname{erf}\frac{1}{2\tau^{1/2}} + \frac{2}{\pi^{1/2}}\tau^{1/2}\left[e^{-1/4\tau}-1\right] \qquad (1)$$

and for 'perfect stirring' as

$$\frac{C-C_b}{C_0-C_b} = \frac{8}{\pi^2}\sum_{n=0}^{\infty}\frac{1}{(2n+1)^2}e^{-\frac{(2n+1)^2\pi^2\tau}{4}} \qquad (2)$$

where $\tau = Dt/\delta^2$, D = diffusion coefficient of ionic species, cm ^{2} sec $^{-1}$, t = time after current interruption, sec , δ = effective boundary layer thickness (cm), C_0 = initial concentration of ionic species (involved in the electrode reaction) at the electrode-electrolyte junction ($x = 0$) , C = concentration of ionic species at $x = 0$, $t > 0$, C_b = bulk concentration of ionic species in electrolyte

Equations 1 and 2 are re-arranged forms of solutions to related problems in heat conduction[1] Equation 2 may be rendered in an alternative form which is useful for computation when τ is small, namely

$$\frac{C - C_b}{C_0 - C_b} = 1 - 2\tau^{1/2} \sum_{n=0}^{\infty} (-1)^n \left\{\frac{1}{\pi^{1/2}} e^{-n^2/\tau} - \right.$$
$$- \frac{n}{\tau^{1/2}} \left[1 - \operatorname{erf} \frac{n}{\tau^{1/2}}\right] - \frac{1}{\pi^{1/2}} e^{-(n+1)^2/\tau} +$$
$$\left. + \frac{n+1}{\tau^{1/2}} \left[1 - \operatorname{erf} \frac{n+1}{\tau^{1/2}}\right]\right\} \tag{3}$$

For very small τ, equation (1) may be approximated as:

$$\frac{C - C_b}{C_0 - C_b} = 1 - \frac{2}{\pi^{1/2}} \tau^{1/2} \tag{4}$$

Similarly, equation 3 may be reduced in form for small τ since all terms become zero for $n > 0$ The result is identical with equation 4 Thus, for small τ, the time behaviour of concentration at $x = 0$ is essentially independent of conditions at the outermost part of the boundary layer, that is, irrespective of the presence or absence of stirring

Because of the equality of the solutions given by equations 1 and 2, 3 for small τ, it is suggested that this result may be utilized for the evaluation of boundary layer effective thickness in electrolytic systems This may be accomplished by analysis of the decay of concentration polarization upon current interruption By the Nernst relation

$$\frac{C - C_b}{C_0 - C_b} = \frac{\exp[ZF\eta/RT] - 1}{\exp[ZF\eta_0/RT] - 1} \tag{5}$$

where η_0 = concentration polarization at time zero, η = remaining polarization at $t > 0$, F = Faraday constant, R = gas constant, T = °K, Z = number of electrons in the electrode reaction The approximation to equation 1 given in equation 4 is valid provided

$$\operatorname{erf} \frac{1}{2\tau^{1/2}} \approx 1 \text{ and } e^{-1/4\tau} \approx 0$$

Arbitrarily choosing erf $1/2\tau^{1/2} = 0\ 99$ yields an upper limit of $\tau = 0\ 075$, whereas $e^{-1/4\tau} = 0\ 01$ sets a limit of $\tau = 0\ 054$ Taking a limit of $\tau = 0\ 05$ together with $D = 10^{-5}$ cm ^{2}/sec , it may readily be seen that for the very thin boundary layers encountered in stirred systems ($\delta \approx 10^{-3}$ cm), the overvoltage measuring device should be able to resolve time to better than 5 msec., suggesting an oscilloscopic technique For thicknesses of about 0 5 mm , encountered in natural convexion systems, time resolution need only be better than about 10 sec , which is well within the range of chart recorders

In the dimensionless time $\tau = 0\ 05$, the concentration (activity) fraction has dropped from unity to about 0 75 The fractional decay of polarization depends on the initial value before current interruption, according to equation 5 At 25° C and for $z = 2$, an initial polarization of 30 mV will have decayed to about 14 6 mV in the interval $0 < \tau < 0\ 05$ From the relationship of equation 5 with equations 1–4, it is clear that for any hydrodynamic conditions, such as stirring or its absence, all anode concentration polarization data can be normalized according to equation 5 and fitted to a master curve (equation 4) provided the real time-scale (in sec) is multiplied by D/δ^2 Since D is generally known, a graphical method may be used to cause a plot of the function of η, η_0 given in equation 5 versus time to be superimposed on a master plot the abscissa of which is rendered in dimensionless time τ, such as that given by equation 4 for $0 < \tau < 0\ 05$

From equation 4, it may be seen that the time required to attain a given fractional decay varies as the square of the boundary layer thickness δ, indicating that the proposed graphical method will permit a good resolution of the actual magnitude of δ Equations 1–4 may also prove useful as a means for separating concentration polarization from other types of overvoltage

Work is in progress to prepare analytical solutions similar to equations 1 and 2 for a concentration contour which is better than the linear approximation for actual systems. Functional tables for equations 1 and 2 over a wide range of τ and tables of the general term of equation 5 are in preparation

Pyrolytic Carbon Formation from Carbon Suboxide

ALMOST all the extensive work done on the formation of pyrolytic carbon films has consisted of the decomposition of a hydrocarbon on non-metallic substrates like porcelain or artificial graphite Work is in progress in our laboratory investigating the kinetics and mechanism of carbon film formation on glazed porcelain from carbon suboxide (C_3O_2)[1] In the course of this work, it was of interest to look briefly, initially, at the effect of some different substrates on the qualitative rate of carbon formation and more particularly on the nature of the film formed

Very pure C_3O_2, entrained in pre-purified helium, was pyrolysed at 713° C for about 3 hr over porcelain, electrolytic nickel and copper foils, and reagent grade platinum foils The concentration of C_3O_2 at the pyrolysis temperature was about 6×10^{-6} mole/l Tenacious and hard carbon films were obtained, with the rate of film formation on nickel being roughly four times that on the other substrates

The carbon films were separated from the metal substrates by acid treatment prior to studying their structure by transmission electron diffraction and

transmission electron microscopy. 50-kV. electrons, having a beam width of 10μ, were used. Fig. 1 (*a*) shows the diffraction pattern for the film carbon resulting from deposition over a copper substrate. Diffuse halos, corresponding to the (10) and (11) reflexions of a polycrystalline, turbostratic carbon[2], are observed. The absence of a strong (002) reflexion when the incident electron beam is normal to the film surface is indicative of preferred orientation of the basal planes parallel to this surface. Diffraction patterns very similar to Fig. 1*a* were obtained from the film carbon deposited on a porcelain or platinum substrate.

On the other hand, the diffraction pattern (Fig. 1*b*) of the film carbon deposited on the nickel substrate is characteristic of a material of substantial crystallite size, in which the crystallites have extensive three-dimensional ordering. Table 1 compares the *d*-spacings for the film carbon (d_{fc}) with comparable spacings calculated from the graphite lattice (d_g). Similar diffraction patterns for carbon films deposited on porcelain, copper, or platinum are obtained only when the separated films are ultimately heated in excess of 2,000° C.

Fig. 2 is an electron micrograph of the carbon film deposited on nickel. Variations in the thickness of the films are evident. In addition, the presence of small, white circular spots is noted. It is suggested that these spots were formed by the removal by acid treatment of inclusions of nickel and/or nickel carbide which were originally present, but this has not been verified. From work on the interaction of evaporated carbon films with a similar nickel substrate on subsequent heat treatment, it is known that substantial inter-diffusion of nickel and carbon occurs at 500° C. and above (Banerjee, B. C., and Walker, P. L., unpublished results).

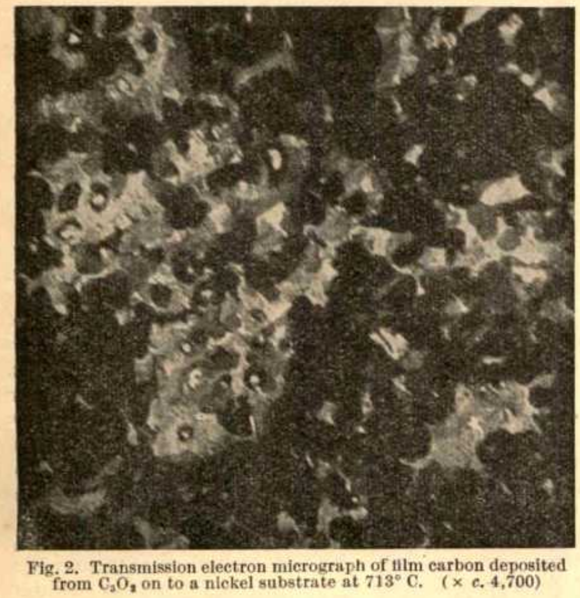

Fig. 2. Transmission electron micrograph of film carbon deposited from C_3O_2 on to a nickel substrate at 713° C. (× *c*. 4,700)

These results clearly suggest that more attention might be paid to the effect of the substrate in work on the formation of pyrolytic carbon films. In particular, substrates of nickel and iron are of interest. They are highly active catalysts for the decomposition of carbonaceous gases, apparently because of the incomplete filling of their 3*d* bands. In addition, they markedly increase the crystallinity of the carbon formed as a decomposition product. The effect of nickel is clearly evident from this work. The effect of iron, both on rate of formation and structure of carbon, has been previously shown for carbon monoxide decomposition[3].

BIOCHEMISTRY

Changes in Adenine Nucleotides in the Muscles of Some Marine Invertebrates

Hitherto it has been generally accepted that most vertebrate muscles contain an enzyme specific for the deamination of 5′-adenylic acid (AMP) which is formed principally from adenosine triphosphate (ATP). On the other hand, in the case of invertebrates the presence of such an enzyme has been questioned[1].

Recently we have studied the changes in adenine nucleotides in the muscles of some marine invertebrates (prawn, squill, crab, squid, and some sea shells), and observed that those of prawn, squill, and crab contain certain amounts of 5′-inosinic acid (IMP) in addition to AMP, while in others AMP alone is accumulated.

Chopped muscles of each animal were stored in a glass-covered dish at an ambient temperature of − 5° C. in order to minimize bacterial effects. Two gm. of muscle were ground by hand in a mortar in 20 ml. of cold, 4 per cent perchloric acid solution. The extract was filtered and 10 ml. of the filtrate were used for

analysis. Nucleotides, nucleosides, and bases were separated and determined by the hydrochloric acid gradient elution system on 'Amberlite *IRA*-400' or by paper chromatography. The details of the system have been described previously[2]. In Table 1 the concentrations of the compounds found to be present after various time-intervals are shown.

From these results it can be seen that ATP decreased during storage, with rapid accumulation of IMP in the dorsal muscle of carp, while in the case of squill, prawn, and crab IMP was found in small quantity in living muscles and then gradually accumulated. Furthermore, in other muscle samples AMP alone was found in living or post-mortem muscles.

The rates of disappearance of ATP and of ADP were very rapid for squid and were comparable with those for fish, but the other animals tended to require more time for the onset of post-mortem changes. Especially, the changes in the muscle of abalone were very slow. AMP accumulation continued for a long time. Adenosine, inosine that might be formed and the purine bases, adenine and hypoxanthine, that would be released in the hydrolysis or phosphorolysis of nucleosides could not be found in abalone muscle even after 45 days.

Further interesting aspects of the changes are the formation of inosine and hypoxanthine from AMP of squid, surf-clam, and scallop. Inosine was principally found in the muscles of surf-clam and of scallop while hypoxanthine was found in squid.

The occurrence of these compounds might be considered to prove the existence of the deamination of adenosine or adenine. The activity of adenosine deaminase has already been recognized in squid muscle[3]. On the other hand, according to Florkin[4], invertebrates are reported to contain adenase but no adenosine deaminase. If the existence of adenosine deaminase is ascertained in the muscles of surf-clam and of scallop, as in the case of squid, the new evidence will be accepted to support the idea of the deamination mechanism of adenosine in the muscle of invertebrates. This matter is under consideration.

Effect of Charcoal on the Behaviour of Adenine Nucleotides in Ion-Exchange Chromatography

Charcoal has been used widely for selective adsorption of nucleotides from reaction mixtures and tissue preparations. In experiments reported here three commercially available grades were all found to adsorb quantitatively and to elute reasonably satisfactorily the mono-, di- and tri-phosphates of adenosine; these charcoals were 'Norit', two batches of purified, activated charcoal supplied by Hopkin and Williams, Ltd., and a gift sample of 'Ultrasorb *ZX*' from British Carbo Norit Union, Ltd.

For each trial, between 5 and 10 mgm. of the sodium salts of the individual nucleotides were dissolved together, the solution diluted to about 250 ml. and brought to *p*H 2 with *N* hydrochloric acid. About 4 gm. of charcoal were added, and the mixture stirred vigorously for 15 min. in an ice bath. Under these conditions the nucleotides were quantitatively adsorbed, as indicated both by optical density of the filtrate at 260 mμ and by the orcinol test. The charcoal was then washed with water to neutrality and eluted, under suction on a filter funnel, with several lots of 0·5 per cent ammonia in 25 per cent ethyl alcohol. Using a total eluant volume of 250–300 ml., 80–95 per cent recovery of the nucleotides was obtained. The ammoniacal eluate was subjected directly to ion-exchange chromatography, using the resin in the chloride form, a column of size 1·5 × 3·0 cm., and the elution system of Cohn and Carter[1]. Elution was followed by absorption measurements at 260 mμ of the individual fractions, by pentose estimations, and also (for ADP and ATP) by estimating the 'labile phosphate' liberated by 15 min. hydrolysis at 100° C. in 1·0 *N* hydrochloric acid. The summarized results are as follows.

Provided they had not previously been in contact with charcoal, mixtures of the three adenosine phosphates behaved normally as regards the order and position of elution of their constituents; in other words, they behaved as described by Cohn and Carter (Fig. 1*a*). But after being adsorbed and eluted from any of the charcoals tested, no nucleotide material was removed from the column by the AMP eluant. The ADP eluant, on the other hand, removed quantitatively both the AMP and the ADP, but as a single peak the elution position of which was somewhat behind that normal for ADP (Fig. 1*b*). After suitable

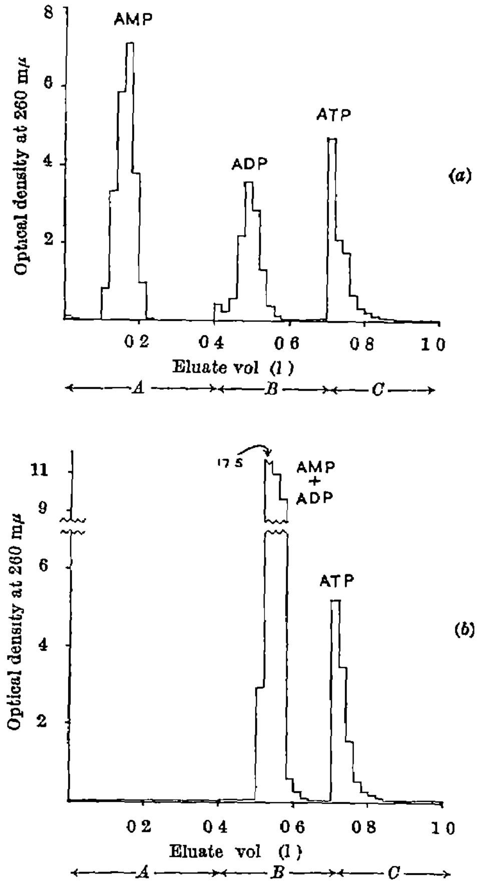

Fig. 1. Effect of charcoal on the chromatographic behaviour of AMP, ADP and ATP. (*a*) Direct chromatography of authentic nucleotides, (*b*) chromatography of nucleotides after charcoal treatment. 'Dowex'-1-chloride, X – 10, 2–400 mesh. Column size, 1·5 cm × 3·0 cm. Eluants: *A*, 0·003 N HCl, *B*, 0·02 N NaCl + 0·01 N HCl, *C*, 0·2 N NaCl + 0·01 N HCl

dilution (to about twice the volume), and adjustment to pH 8–9, the mixed peak was applied to a second column and re-eluted. The two nucleotides then usually separated satisfactorily (Fig. 2), although with the charcoal 'Ultrasorb *ZX*' passage through a third column was needed to obtain full resolution, in this particular case the AMP eluant was used at double its usual strength, but it seems likely that normal strength eluant would have achieved the same result. After adsorption and release of a nucleotide mixture from 'Ultrasorb *ZX*', unsuccessful attempts were made to resolve it on a single resin column by using eluants of increased strength in the first step. Double strength AMP eluant was wholly ineffective, but ADP eluant at half its usual strength removed a peak, this, however, did not consist of AMP alone, since it contained acid-labile phosphate.

AMP was eluted normally when applied alone to a resin column in the ammonia–ethanol solvent without coming into contact with charcoal, whereas, if applied in a quantity of the solvent which had previously been used to wash charcoal (the activated, purified sample), it was no longer eluted with the AMP eluant, but came off only in the position usual for ADP. Prolonged preliminary washing of charcoal with (*a*) 0·5 M ethylenediaminetetraacetic acid (sodium salt), (*b*) 0·1 N hydrochloric acid, or (*c*) the ammonia–ethanol eluant, did not eliminate its influence on the chromatographic behaviour of AMP afterwards adsorbed on it. On evaporation, ammonia–ethanol washings from charcoal left a slight, unidentified solid residue.

These results point to a need for caution in the selection and use of charcoal for nucleotide adsorption, particularly if subsequent resin chromatography is contemplated. None of the samples proved satisfactory, but some were worse than others. The observations indicate very strongly the presence in charcoal of a substance which induces AMP to behave anomalously on chloride resin. Although the substance is soluble in ammoniacal alcohol, even prolonged washing with many changes of the solvent, which continued to extract the substance, did not render the charcoal innocuous. Thus, the substance appears either to be present in relatively large amounts or to exert its effect in very small quantities. Its mode of action is obscure. Should a loose association or complex with AMP be formed, it must be presumed that this is broken up on elution from the first resin column, since the AMP and ADP are then easily separable on a second column. Nevertheless, the AMP still does not behave quite normally, although it now comes away from the column as a single clear peak with the AMP eluant, more elution than normal is required to release it. It seems probable that a much smaller amount of the interfering substance must be applied to the second column than to the first. On the complexing hypothesis, if there were only sufficient of it to involve a part of the AMP present on this second column, it might be expected that the remaining free AMP would come off in its normal position, but the complexed fraction again only with the stronger

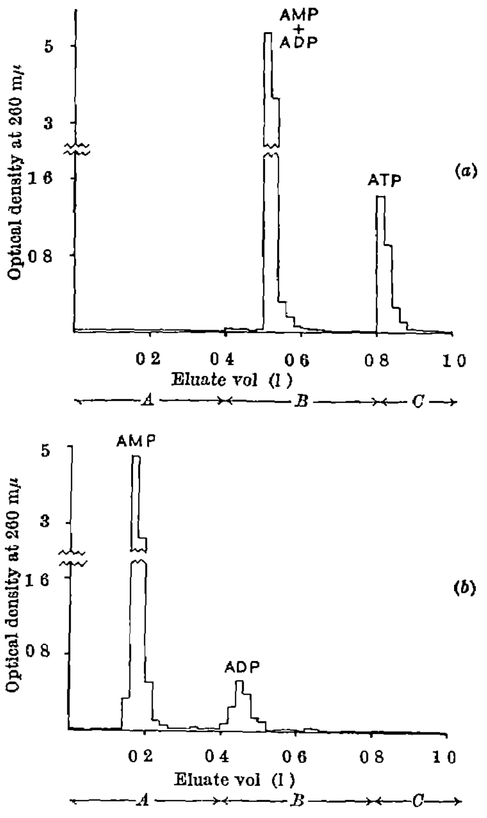

Fig. 2. Passage of a charcoal-treated nucleotide mixture through two successive resin columns. (*a*) Chromatography on first column, (*b*) resolution of the mixed AMP–ADP peak on the second column. Experimental details as in Fig. 1

eluant, so that two peaks should result. Actually there is only one peak, yet a delayed one. Hence on the columns, the AMP always behaves like a single substance the elution point of which is delayed progressively as the amount of the interfering substance increases. No similar interference after charcoal treatment was found when formate columns were used, even though considerably more charcoal was then necessary in the nucleotide isolation step.

Certain anomalies in the chromatographic behaviour of nucleotides resulting from their previous treatment have already been recorded. Lund *et al.*[3] found that treatment of ATP with cation-exchange resins caused it to behave aberrantly when it was chromatographed later on paper, occupying, with some solvents, the position usual for ADP. Laws and Stickland[4] observed that if nucleotides are isolated from yeast by precipitation with barium acetate, the presence of large amounts of water-soluble barium salts causes AMP to behave abnormally during chromatography, on the anion-exchanger 'Amberlite *CG*–400' it is then eluted in a solution intermediate in strength between those usual for AMP and ADP.

This work formed part of a Ph.D. thesis submitted to the University of London; it is a pleasure to acknowledge the guidance and helpful criticism of Dr. F. J. Richards.

Changes in the Concentration of Ribonucleic Acid during Wound Tissue Regeneration

The metabolism of ribonucleic acid (RNA) in regenerating wound tissue may be expected to be of special importance since the synthesis of protein is one of the principal metabolic activities of this tissue[1,2]. The relative amount of RNA in this tissue at different stages of regeneration should give some insight into the protein metabolism. A complicating factor is the fact that considerable amounts of two quite different types of protein are formed, the intracellular 'metabolically-active' proteins, and collagen.

The concentration of RNA in regenerating wound tissue was determined by analysis of tissue obtained from adult female rats. Because of the marked influence of dietary protein on the rate of regeneration[3,4], these animals were fed identical amounts (8 gm./day) of a protein-free diet for 3 days prior to wounding and for the balance of the experimental period. In this way, the experimental animals served as their own source of nitrogen for the synthesis of protein and nucleic acids. The procedure for making standard wounds has been described previously[2,3]. At intervals after wounding, the regenerating tissue was collected and immediately homogenized by repeated grinding in a mortar with sand and small amounts of cold water. After determining the nitrogen in an aliquot of the homogenized tissue (micro-Kjeldahl), the remainder was fractionated to separate the RNA from the deoxyribonucleic acid (DNA) by the method of Schmidt and Thannhauser[5,6]. The phosphate content of the RNA was measured[7]. Less than 3 per cent of the total phosphate in this fraction was inorganic, this inorganic phosphate may have arisen from the hydrolysis of phospho-proteins during the fractionation procedure[8]. Since phospho-lipids, free nucleotides and inorganic and sugar phosphates had been removed by previous procedures, it was assumed that essentially all the phosphate in this fraction must come from RNA.

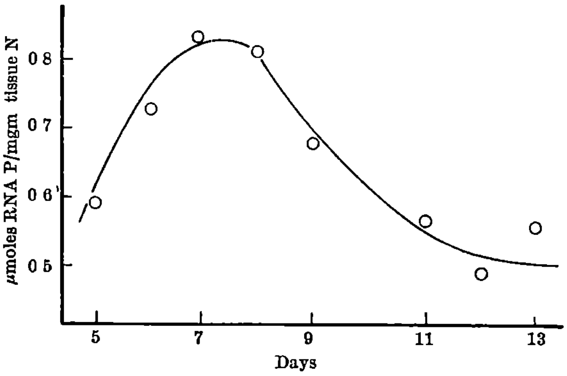

Fig. 1. RNA content of regenerating wound tissue in μmoles of phosphorus per mgm. of tissue nitrogen at various times after wounding. Each point represents the data from the analysis of tissue from 5–6 animals

The level of RNA in the regenerating tissue at various intervals after wounding is shown in Fig. 1. The highest concentration appears to be reached in about 7–9 days after wounding, thereafter it decreases to a lower and relatively constant level. In part, this decrease is due to the accretion of nitrogen in the wound tissue with time. However, even when calculated on the basis of tissue weight, there is still an appreciable decrease in the amount of RNA.

If the types of RNA molecules being synthesized by cells can be shown to change, it might be considered to be indirect evidence that new or different proteins are being synthesized. A change in the type of RNA, or the proportion of the various kinds of RNA produced by the cell, may be signalled by a change in the proportion of purines to pyrimidines of the RNA fraction of the tissue. In a further experiment, it was possible to obtain a sufficient quantity of regenerating tissue to enable both the ribose and phosphate content of the RNA fraction to be measured. The amount of ribose in the RNA fraction was determined by the orcinol method[9]. From the data on the analysis of ribose, which is a measure of the purine nucleotides only[10], and that of the phosphate, which is proportional to the total nucleotide content of the nucleic acid, a ratio which approximates the proportion of pyrimidines to purines in the RNA may be calculated (Table 1). During the early phases of regeneration, the RNA in the wound tissue contains about the same amounts of purine and pyrimidine nucleotides, on a molar basis, later the RNA fraction

Table 1. PURINES AND PYRIMIDINES IN RNA OF REGENERATING WOUND TISSUE

Days after wounding	μmoles Ribose per mgm. tissue nitrogen	μmoles Phosphate per mgm. tissue nitrogen	Ratio of purine to pyrimidines*
5	0.25 ± 0.08	0.46 ± 0.11	1.11 ± 0.12
8	0.60 ± 0.11	1.16 ± 0.12	1.05 ± 0.07
12	0.41 ± 0.09	1.01 ± 0.11	0.70 ± 0.07
15	0.33 ± 0.04	0.88 ± 0.12	0.61 ± 0.09

* The standard error was calculated from the purine/pyrimidine ratios for individual tissue samples

appears to contain an appreciably larger proportion of pyrimidine than purine nucleotides

This change in proportion of nitrogen bases might be interpreted to mean that different types of RNA are being synthesized at different stages of regeneration, this, in turn, may presage a change in the nature of the protein synthesized in the regenerating tissue Large amounts of collagen begin to appear in the wound tissue only after the 8th day after wounding[11,12] Since the amino-acid composition of collagen (and presumably its intracellular precursors also) is so radically different from that of the 'metabolically-active' proteins, it does not seem improbable that a type of RNA with radically different nucleotide composition might be involved in the synthesis of the collagen precursors It must not be overlooked that even though much collagen may be formed, some of the 'metabolically-active' proteins are also being formed at the same time Thus, if the change in the nucleotide composition is related to the synthesis of collagen precursor, it may be expected that the actual difference in the types of RNA involved is much greater than is indicated by the above results

Phosphorylserine as a Constituent of Phosphoproteins from Plasma of the Laying Hen

ALTHOUGH it has been well established that the blood of the laying hen contains phosphorus compounds, the quantities of which are increased immediately preceding and during ovulation[1,2], the nature of some of these substances has only recently been subject to chemical investigation Dilution of plasma from the laying hen results in the precipitation of a complex of lipid and a phosphoprotein, though by far the greater proportion of the total phosphoprotein present in the plasma remains in the supernatant[2]. Designation of these materials as phosphoproteins has rested entirely on the finding that inorganic phosphate is liberated when they are incubated with dilute alkali[3], but the manner in which the phosphorus is bound has not been reported. Phosphoproteins in general and particularly that from egg yolk, contain their phosphorus as phosphorylserine[4,5], and this has now been sought in acid hydrolysates of both the phosphoprotein fractions of the plasma.

Plasma from laying hens was diluted with 9 vol. water[2] and the precipitated lipophosphoprotein collected by centrifugation. The supernatant was precipitated by trichloroacetic acid added to a final concentration of 10 per cent (w/v) and both this precipitate and that of the lipophosphoprotein was extracted with chloroform/methanol (2 1 v/v)[6]. The lipid-free residues were hydrolysed in 2 *N* hydrochloric acid at 100° and the supernatants, containing 80–96 per cent of the total phosphorus of the fractions, were dried over phosphorus pentoxide and potassium hydroxide The residues were fractionated on 'Dowex 50' (× 12)[7] After elution of a fraction containing inorganic phosphate a second major phosphate fraction was eluted at a point corresponding to that at which phosphorylserine was eluted when run through the same column No other fractions were detected The presumptive phosphorylserine fraction contained between 20 and 54 per cent of the organic phosphorus present in the hydrolysate added to the column and was further purified by high-voltage electrophoresis on paper at *p*H 1 5 (ref 8) Under these conditions 80–86 per cent of the phosphorus moved as a single component at a rate identical with phosphorylserine The remaining 14–20 per cent formed a single slower-moving component Both components reacted with ninhydrin When eluted and hydrolysed to yield the constituent amino-acids, two-dimensional paper chromatography showed that the component migrating at the same rate as phosphoserine yielded only serine The molar ratios of phosphorus to serine in two experiments were 1 0 and 1 3 The second minor fraction yielded mainly serine and glutamic acid with traces of alanine and possibly leucine. The total yield of phosphorylserine was 38–39 per cent of the organic phosphorus of the phospholipoprotein residues and 17–20 per cent of that present in hydrolysates of the phosphoprotein derived from the supernatant A specimen of phosvitin subjected to the same procedure yielded phosphorylserine equivalent to 25 per cent of the organic phosphate present in the hydrolysate No phosphoproteins were detected in plasma of the non-laying hen or the cockerel (cf ref 2).

These experiments appear clearly to establish phosphorylserine as being the only major single phosphorylamino-acid detectable in partial hydrolysates of phosphoproteins from plasma of the laying hen The overall recovery, when compared with that obtained with phosvitin, suggests that all the phosphoprotein phosphorus may be bound in this manner.

I thank Dr M E Coates, National Institute of Research for Dairying, Shinfield, Nr Reading, for a generous supply of birds

Distribution of Ribonucleic Acid in Subcellular Fractions of Various Regions of the Central Nervous System of the Rat

The distribution of ribonucleic acid (RNA) in the subcellular structures of whole brain was studied by Brody and Bain[1], and by Aldridge and Johnson[2], and in the rat brain cortex during development by Keup[3]. We showed previously that appreciable differences exist in the distribution of nucleotides and RNA and in the incorporation of phosphorus-32 in this RNA in various brain regions[4]; we have now studied the RNA content of the subcellular fractions of each region of the central nervous system examined previously and the incorporation of phosphorus-32 in the RNA fractions thus isolated.

Table 1. Distribution of Ribonucleic Acid in Subcellular Fractions of Various Regions of the Rat Central Nervous System

Region	Nuclei			Heavy mitochondria		Light mitochondria		Endoplasmic reticulum (microsomes)		Cytoplasmic fluid		Myelin fraction

Medulla oblongata	0·98	9·3	0·154	1·01	16·1	1·21	10·9	2·45	31·6	0·68	14·9	0·29	17·2

We have completed six experiments using twenty rat brains on each occasion. The rats received intraperitoneal injections of phosphorus-32 (200 µc/100 gm body-weight) and were decapitated after one, three and five days. The heads were immediately plunged into ice-cold 0·9 per cent sodium chloride and the brains were removed rapidly in a manipulation cabinet at 0° C. Various parts of the brains were separated by dissection: olfactory lobes, grey matter and white matter of the cerebrum, hypothalamus, cerebellum and medulla oblongata. The subcellular fractions were isolated using 0·3 *M* sucrose by the classical method of Hogeboom, Schneider and Pallade[5], as slightly modified by Aldridge and Johnson[2]. The purification of the nuclei did not seem sufficient and we therefore employed the following modification. Centrifuging at 1,000*g* for 10 min with a 0·3 *M* sucrose solution gave a precipitate mixed with capillaries and blood, these forming a lower layer in the centrifuge tubes. The upper layer was separated, re-homogenized with 0·3 *M* sucrose and centrifuged at 1,000*g* for 10 min. The precipitate obtained was mixed with 20 volumes of 1·5 *M* sucrose and centrifuged at 145,000*g* for 90 min in a 'Spinco' model *L* ultracentrifuge. This treatment gave a precipitate consisting of nearly pure nuclei and a supernatant film containing myelinated structures slightly contaminated with their cytoplasm and with axonal fragments. These facts were demonstrated by electron microscopy. It was estimated that about 90 per cent of the supernatant consisted of myelinated structures. This was confirmed by the chemical analysis, which showed that the supernatant contained, on average, about 55 per cent of the total phosphatides for all the different parts, while the cytoplasmic fluid contained only about 2 per cent and the totality of mitochondria 24 per cent[6].

The heavy and light mitochondrial fractions and the microsomes were separated by the method of Aldridge and Johnson[2].

After extraction of the acid-soluble matter by 0·6 *N* perchloric acid, each subcellular fraction was treated with cold ethanol and then, to extract the lipids, treated by the method of Bloor[7]. RNA and deoxyribonucleic acid (DNA) were separated by the procedure of Schmidt and Thannhauser[8] and the RNA fraction was purified by a technique described elsewhere[4]. The specific activity of RNA phosphorus was determined on solutions at infinite thickness in an end-window Geiger counter (mica window 1·8 mgm/cm^2). The results of the experiments are shown in Tables 1 and 2.

The ratio of RNA to protein was found to be lowest (0·29–0·57) in the myelin fraction, higher in the heavy mitochondria (0·54–1·08) and, on average, higher still in the light mitochondria (1·01–1·4), while for the nuclei the values varied from 0·98 to 1·69. For the cytoplasmic fluid the values were of the same order, although rather lower in the cerebellum and the medulla. The highest values were, of course, found in the microsomes. For a given subcellular fraction clear and important differences existed between one part of the brain and another: the highest values for the nuclei correspond to hypothalamus, followed by the olfactory lobes and the grey matter of the cerebrum, the lowest values were for the cerebral white matter and the medulla. The RNA content of the microsomes was fairly constant at about 30 per cent of the total for each region while for the other fraction the RNA content varied appreciably from one region to another. The ratio RNA/DNA, which also gives an indication of the purity of the nuclei, varied between 0·08 and 0·17: the highest values were for the hypothalamus and the cerebral grey matter.

The specific activity of the nuclear RNA at one and three days is clearly higher than that of the other fractions. The same is true at 5 days except for the olfactory lobes and the hypothalamus. A comparison of the results for the specific activity with respect to

Table 2. Specific Activity in Counts/Min µgm of Ribonucleic Acid Phosphorus in Subcellular Structure of Various Regions of the Rat Central Nervous System

Region	Hr	Nuclei	Heavy mito-chondria	Light mito-chondria	Endoplasmic reticulum (microsomes)	Cytoplasmic fluid	Myelin fraction

	120	51	51	42	51	88	29
Cerebellum	24	39	9	9	14	16	—
	84	46	34	31	39	55	47
	120	57	—	—	46	64	46
Medulla oblongata	24	50	9	18	15	13	28
	84	56	30	38	36	38	45
	120	71	—	—	53	39	40

time for the nuclear RNA shows that a maximum exists between the first and fifth day for the olfactory lobes and the hypothalamus, while for the other regions the specific activity at five days is either greater than or equal to that at three days For the hypothalamus and the olfactory lobes the specific activity versus time curve for the nuclei crosses those for the cytoplasmic fluid and the microsomes Thus, our results confirm previous data concerning the high RNA content and great metabolic activity of the olfactory lobes and the hypothalamus[4]

The relatively high RNA content of the myelin fraction recalls former investigations concerning the cytoplasm attached to myelin sheaths and the RNA content of axons It should be mentioned that the relatively high specific activity of the RNA of the myelin fraction cannot be entirely accounted for by a contamination of nuclei, since 90 per cent of the nuclei of the various regions, apart from the cerebellum, contains, on average, only about 10 per cent of the total RNA. In addition, 24 hr after injection the myelin fraction has a specific activity superior to that of any other subcellular fraction apart from the nuclei. It is therefore difficult to attribute this activity to a contamination by mitochondria, microsomes or cytoplasmic fluid

Our nuclear fraction contained 70 per cent of the total DNA in the cases of the cerebral white matter and medulla, 75, 86, 89 and 92 per cent respectively for the hypothalamus, cerebral grey matter, olfactory lobes and the cerebellum It should be noted that the ratio RNA/DNA for our nuclear fraction is generally lower than or at the most equal to that found by Chauveau[9] for the liver and is, for three regions, near that found by Georgiev and Mantiewa[10] for the whole brain

Cystine Content in Hair of Childen as influenced by Vitamin A and Animal Protein in the Diet

RECENTLY, Koyanagi and Odagiri[1] reported that the cystine content of skin of rats dosed with a small quantity of vitamin A is lower than that of rats given a liberal allowance of the vitamin In the presence of methionine, the cystine content increased both with small and large doses of vitamin A We now wish to report on experiments conducted to determine whether the cystine content in the hair of children could be changed by deficiencies of vitamin A in the diet and other factors

Table 1 AMOUNT OF FOODS CONSUMED AND ESTIMATE OF PROTEIN AND VITAMINS PER PERSON PER DAY

Foods	District *A* (gm)	 *B* (gm)	 *C* (gm)

Vitamin A (I U)	1,184	1,235	3,572
Riboflavin (mgm)	0 71	0 63	1 40
Thiamine (mgm)	1 97	0 92	1 21

* Digestibility of protein of barnyard millet is very low.

† Amount of animal origin indicated in parentheses

The survey was done on school children aged 8–9 yr , in the following three districts, (*A*) Yamagata village, situated in the mountainous area where people having a small income eat Japanese barnyard millet and very little fish, (*B*) Teshiromori village, situated in the rice field district where people live on rice and eat a moderate amount of fish; school lunches are served, (*C*) Morioka city, where the diets are comparatively well balanced, children have lunch served at school Food articles available for civilian consumption in three districts are shown in Table 1

To determine the cystine content in the hair, 0 1 gm of hair from the back of the head was hydrolysed in 3 *N* hydrochloric acid at 120° C for 4 hr The cystine content in the hydrolysate was analysed by the phosphotungstic acid method[2]

Effect of diet The results (Table 2) indicate that there are striking differences in cystine content in the hair from the three districts, for example, the figures from district *A* show only 8 1 per cent while those from districts *B* and *C* return 11 4 and 12 5 per cent, respectively. The figures thus correlate closely with the consumption of animal protein

Effect of vitamin A and milk Table 2 gives results in districts *A* and *B* obtained by analysing hair of children supplemented for half a year with shark liver oil (2,500 I U). The cystine content is higher in the hair of children in the supplemented group The observations are in agreement with those on the skin of rats reported by Koyanagi *et al* In district *B* some children were allowed to drink milk liberally, that is, 300–400 c c daily a child for half a year. The cystine content of their hair is remarkably higher than that of children without milk

Table 2 CYSTINE CONTENT IN THE HAIR OF CHILDREN IN THREE DISTRICTS

District	Supplement	Height (cm)	Weight (kgm)	Cystine in the hair (per cent)	
A	None	116 3 ± 6 7*	21 9 ± 2 2*	8 1 ± 0 15*	(21)†
	Shark liver oil	122 0 ± 5 2	22 0 ± 2 2	9 5 ± 2 3	(11)
B	None	121 0 ± 3 1	24 1 ± 1 7	11 4 ± 1 8	(13)
	Shark liver oil	124 7 ± 4 5	24 5 ± 2 6	13 0 ± 1 4	(12)
	Milk	128 7 ± 3 1	26 2 ± 0 5	14 4 ± 0 6	(9)
C		127 5 ± 1 8	26 7 ± 1 2	12 5 ± 1 3	(22)

* Standard deviation of the mean

† No of children indicated in parentheses

Effect of age. Hair of 26 infants was collected in district *C* and analysed In this case, in spite of individual variation the higher values were found more often among the younger group and there was no apparent difference between sexes (9 months, 12 1–15 1, 3 yr , 11 9–14 4, 4 yr, 10 6–13 0, 5 yr , 10 5–13 0, 6 yr , 11 0–12 7, adults, 10–12 per cent)

Effect of disease Through the clinical examination conducted on 75 infants in district *A*, 13 cases of active angular stomatitis, 25 cases of fatty liver and 5 cases of severe malnutrition were found It is remarkable that the cystine content in the hair of infants showing undernutrition showed strikingly lower values than in that of the healthy infants in district *C* (2 yr , 6 0–9 2, 3 yr , 5 5–6 6; 4 yr , 5 8–9 2, 5 yr , 7 2 per cent)

In regard to amino-acid content of nails, Hess[3] reported that the molecular ratios of histidine to lysine to arginine for normal nails were 1 · 6 · 13 while for arthritic nails they were 1 : 5 4 13 5 The three basic amino-acids remained practically constant, while the cystine content decreasd 18 4 per cent So it is fair to state that the cystine content in the hair may be influenced by the condition of health, and by disease, as well as through the diet. Observation on the cystine content of hair led to a postulation that the cystine content of hair may be looked on as a sign of nutritional status for children, or as an indication of the presence of some disease

PHYSIOLOGY

Amounts of Oxides of Nitrogen and Carbon Monoxide in Cigarette Smoke, with and without Inhalation

RECENTLY, Haagen-Smit[1] has referred to the relatively high content of oxides of nitrogen in smoke from cigarettes and cigars It was found that the content of oxides of nitrogen in cigarette smoke varies from 145 to 655 p p m. Furthermore, after inhalation of the smoke into the lungs, no oxides of nitrogen could be detected in the exhaled smoke In view of the very low maximum concentrations of oxides of nitrogen tolerated (Russian workers[2] claim 0 1 mgm /m ^{3} as an average concentration during 24 hr , and 0 3 mgm /m ^{3} as a maximum concentration at one time , for carbon monoxide these concentrations are 2 and 6 mgm /m ^{3} respectively) it was thought interesting to determine how much of these compounds may be taken up as a result of cigarette smoking

Two types of experiments were carried out A smoking apparatus was developed in which normal smoking could be simulated It consists essentially of a spiral washer with xylene for the removal of tars, which may affect the reaction with the Griess-Ilosvay reagent, and of a sampling bottle, a gas meter and finally a magnetically operated valve The latter is connected, through a capillary, with the vacuum line Smoke from a cigarette was drawn in 27-ml. samples into the sampling bottle by opening and closing (2 and 28 sec respectively) the magnetically operated valve The natural smoking process was simulated to such a degree that 15 × 0 5 = 7 5 min were required to smoke a cigarette to a residual length of about 10 mm During this time about 400 ml gas was delivered into the sampling bottle.

In each sample the contents of nitrogen oxides and carbon monoxide were determined by normal analytical methods In a few cases a distinction was made between nitric oxide and nitrogen dioxide From Table 1 it appears that under our smoking conditions approximately equal amounts of nitric oxide and nitrogen dioxide are present The total amount of nitrogen oxides is within the range found by Haagen-Smit for different types of cigarettes.

Table 1 CONCENTRATIONS OF OXIDES OF NITROGEN AND CARBON MONOXIDE IN CIGARETTE SMOKE

(King-size cigarette, relative humidity 45 per cent)

Cigarette	$NO+NO_2$ (p p m)	NO_2 (p p m.)	CO (per cent by volume)	CO_2 (per cent by volume)
1	190			
2	170			
3	180			
4	210			
5	210			
6	180			
7	170			
8	190			
9	190	100	2 2	7 8
10	200	120	2 0	7 0
11	190	80	2 1	

Inhalation experiments were carried out by three separate persons. In each experiment a cigarette was smoked in such a way that 500 ml smoke + additional air were inhaled during each inhalation After exhalation into a 10-litre sampling bottle, the lungs were flushed with four times the amount of air, which was also passed into the sampling bottle. In addition, non-inhalation experiments were carried out by the same persons. The smoke of each pull was kept in the mouth, and then passed into the sampling bottle where it was diluted with air (inhaled through the nose) to a total volume of 2 5 l In both cases 13 × 2 5 = 32 5 l were passed through the bottle, after which the amounts of nitrogen oxides and carbon monoxide were determined

The figures given in Table 2 show that, as a result of inhalation, both the nitrogen oxides and the carbon monoxide are absorbed to a large extent Consequently the amount of these compounds which may be taken up by the body can readily be estimated If 20 cigarettes a day are smoked, 3 0 mgm of oxides of nitrogen (calculated as nitrogen dioxide) and 200 mgm of carbon monoxide may be absorbed These figures are considerably higher than the amounts,

Table 2 CONCENTRATIONS OF OXIDES OF NITROGEN AND OF CARBON MONOXIDE IN CIGARETTE SMOKE, WITH AND WITHOUT INHALATION

Person	CO (per cent by volume)		Absorbed per cent	Oxides of nitrogen $(NO + NO_2)$ (p p m)		Absorbed per cent
	Without inhalation	With inhalation		Without inhalation	With inhalation	
A	2 1*	0 37	82	180	23	87
B	2 1*	0 36	82	240	11	95
B				220	12	95
C	2 1*	0 27	87	180	8	96
C		0 37	82	220	10	96

*The concentrations have been converted to those in the undiluted smoke The dilution factor was calculated from the content of carbon monoxide in the 10-l sampling bottle and the average value of 2 1 per cent as determined from the experiments with the smoking apparatus namely 12 × 0·1 = 1·2 mgm. oxides of nitrogen and 12 × 2 = 24 mgm. of carbon monoxide, regarded as the maximum which can be safely tolerated.

Whether the effect of incidental inhalation of relatively high concentrations of noxious compounds is greater than that from continuous inhalation of a much lower concentration is difficult to establish. It should be remarked, however, that for an evaluation of the health effects of smoking the possibility of synergism[3], caused by the simultaneous presence of both nitrogen oxides and carbon monoxide, should also be taken into account.

Sodium and Potassium Content in the Muscles of Hibernating Animals

It has long been known that tissues exposed to low temperatures *in vitro* lose potassium while on the other hand there are few published reports regarding sodium exchange during the same conditions[1,2]. In a previous report[3] we have demonstrated that the potassium/sodium ratio in the muscles of fishes caught in cold arctic waters is low when compared with fishes from boreal waters. The very same variations with temperature were found to take place in specimens of the same species both in Nature (*Gadus*) and in the laboratory (*Cottus*).

As we were at the same time working with problems on the physiology of hibernation we were led to suspect that the extreme hypothermia normally occurring during hibernation in these animals might induce even more marked changes in electrolyte composition of the muscle cells.

The animals used were the common European hedgehog, *Erinaceus europaeus* L., and the bat, *Myotis daubentonii* L. The muscle samples were dry-ashed at 550° C and the content of sodium and potassium estimated by flame-photometry.

In the case of the hibernating animals referred to, we found a rather surprisingly high content of sodium in the muscles, compared with that reported in the literature on other mammals, and also confirmed by my own analysis on the rat, Fig. 1. Furthermore, we found the sodium content to be fairly constant throughout the year, despite the extreme changes in body temperature taking place during this time.

Thus, when compared with other homoiothermic vertebrates having about the same plasma composition, the hibernators differ greatly. Whether or not this has something to do with differences in the physiology of the muscle cells, the present results do not demonstrate. It seems to us, however, that the hibernators, which behave much like poikilotherms in the winter, may somehow be prepared by a high sodium-level to stand the effect of low temperatures on the sodium content of the tissue.

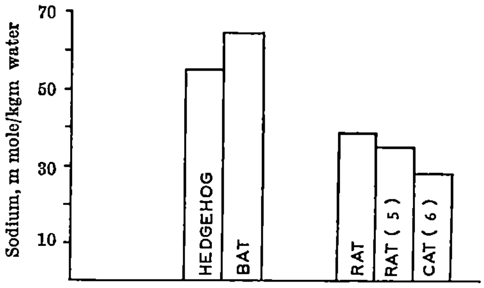

Fig. 1. Sodium content in the muscles of hibernating animals (hedgehog, bat) and some other mammals (refs. 5, 6)

It may be worth considering the same tendency found in arctic fishes, where a high sodium content was encountered at low temperatures. It thus seems that the ability to stand low temperatures may in some way or other be connected with the sodium metabolism of the cell.

Whereas the level of sodium is fairly constant throughout the year, we found distinct changes in the potassium content of the muscles. Muscle samples have been taken from hedgehogs in the period from May to March, while the samples from bats are from November to April only. As seen in Fig. 2, there is an increase in the potassium content of the hedgehog muscles during the first months of hibernation (October–December) and from then on a distinct decrease. In the months October–November the body temperature of the hedgehog varies greatly, changing from the normal level (35° C.) to environmental temperatures (5° – 8° C. in our animal room) in less than 24 hr. In this 'pre-hibernating' period some animals take food, while others are in manition, with no apparent effect on the sodium–potassium level. From about December the animals are in deep hibernation. As regards the bats their body temperatures change in about 10–30 min., and their period of manition begins about September and lasts until about May.

Contrary to the expectations we might have from our results obtained on fish muscles, we thus see that the hedgehog muscles gain potassium in the first part of the hypothermic period. It is rather difficult to explain this considering the temperature effect alone. However, we want to direct attention to certain observations made in this Laboratory[4] on changes in some blood constituents in the 'pre-hibernating' period. In this period we found a marked hæmolysis corresponding to one-third of the total erythrocyte volume. A tentative explanation might therefore be

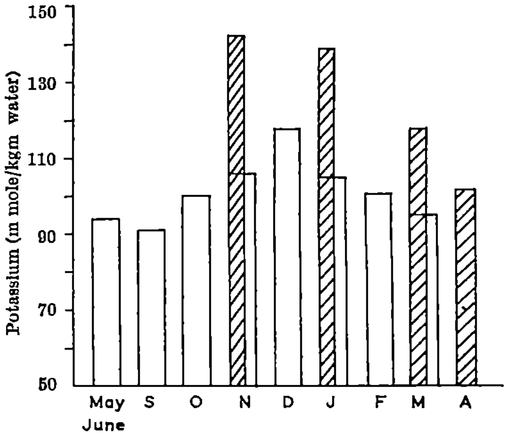

Fig. 2. Potassium content in the muscles of hedgehog and bat at different times of the year. □, hedgehog, ▨, bat

that part of the potassium set free during this hæmolysis is accumulated by the tissue cells Unfortunately we are at present unable to present enough data on the level of potassium in plasma Only small changes in this level are necessary, however, to induce an increase in cellular potassium, due to the effect of the Gibbs–Donnan equilibrium This explanation seems the more reasonable as we found the time of the year to be the important factor no differences in muscle potassium were observed between samples from animals with normal or hypothermic body temperature

The effect of hæmolysis in October–November seems to last until December This lag might be explained on the assumption that the extrusion of salts through the kidney is extremely slow in animals in deep hibernation With the progress of time (December–March) this slow process, however, leads to a reduction of cellular (and plasma) potassium

Regarding our results for bats, these are in accordance with such considerations

Diuresis due to Stress in Cattle

In the course of investigation of some aspects of renal function in adult dairy cattle, it was noted that there was a marked diuretic response to a painful stimulus The animals used were non-lactating, non-pregnant Ayrshire dairy cows accustomed to experimental procedures, and the stimulus was puncture of the brachial artery by the technique described by Fisher[1], which, despite the use of local anæsthetic, always caused some discomfort Arterial puncture was carried out during continuous urine collection by an indwelling urethral catheter for renal clearance measurements In association with the increased rate of flow after arterial puncture, urine became noticeably paler in colour, and there was a marked fall in urinary bicarbonate concentration Cystometric measurement of bladder pressure showed that there was no variation in intracystic pressure at the onset of diuresis, and, on the basis of these observations, it was assumed that the increase in the rate of urine collection was a true reflexion of increased rate of formation, rather than the expulsion of uncollected urine from the bladder

The discomfort of arterial puncture, in some animals, caused an immediate diuresis of 200–300 per cent of the previous mean rate of urine flow The onset and regression of this response were usually rapid One cow, with a mean rate of urine flow of 9 6 ml /min, showed a diuresis of 28 5 ml /min in the 5 min following arterial puncture, the rate returning to 8 5 ml /min in the next 5 min period After repeated experiments on the same animals, this type of response was preceded by a diuresis associated with the preliminary procedure of clipping, swabbing, and anæsthetizing the site for puncture Fig 1 illustrates the diuresis which occurs on carrying out arterial puncture, preceded by the response to preparation of the site.

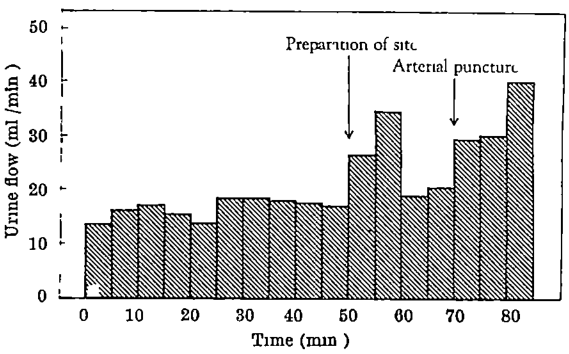

Fig 1 The effect of arterial puncture, and of clipping, swabbing, and anæsthetizing the site on the urine flow of a normal cow

Rydin and Verney[2] demonstrated a marked inhibition of urine flow of hydrated dogs following emotional stress, with good evidence that this response was due to the release of antidiuretic hormone Andersson and Persson[3], however, reported that, in hydrated goats, painful or emotional stimuli did not result in any alteration in the rate of urine formation In man, Miles and De Wardener[4] described an emotional diuresis which occurred on bladder catheterization, or resulted from apprehension of a surgical procedure They attributed the rise in salt excretion which accompanied this diuresis to three possible causes (1) a rise in glomerular filtration-rate, (2) the inhibition of a salt-retaining hormone, (3) a nervous inhibition of tubular function There are, therefore, marked species differences in renal responses to painful or emotional stimuli

The mean blood pressure of cows may rise markedly on experimental interference[5], but whether the observations reported here are the result of alterations in renal hæmodynamics or of inhibition of the antidiuretic hormone is not known It is, however, clear that experiments on cattle which depend on measurement of the rate of urine flow must be carried out with the minimum amount of stress to the subject

Effects of Thymectomy on the Resistance of Rats to Drowning and Histamine Stress

The thymus has been proposed as a site of hormone production[1] Bomskov *et al*[2] have reported that treatment of normal rats and guinea pigs with calf thymus extract distinctly diminished survival-time of animals exposed to chloroform–air mixtures

The aim of the present work was to determine the degree of resistance conferred by thymectomy on albino male Wistar rats Two procedures were used, one involving resistance to drowning stress and the second resistance to histamine stress

Two hundred and forty male rats averaging 50 gm. were matched by weight and divided into three

Table 1. Effect of Thymectomy on Resistance to Histamine and Drowning Stress

Group	n	Initial body-weight gm. ± S.E.	Final body-weight gm. ± S.E.	LD_{50} mgm./kgm. ± S.E.	Drowning time (sec.) ± S.E.	Percentage difference between two groups	P value
1. Histamine stress							
Group *A* Thymectomy rats	60	52.8 ± 0.4	199.8 ± 2.4	702.9 ± 36.4		A B = + 6.8 A C = + 8.2	0.22 0.13
Group *B* Sham-thymectomy rats	60	52.5 ± 0.5	195.4 ± 2.7	658.4 ± 29.8			
Group *C* Normal control rats	60	52.5 ± 0.4	200.1 ± 2.3	649.4 ± 33.5		*B* C = + 1.4	0.76
2. Drowning stress							
Group *A* Thymectomy rats	19	49.2 ± 0.7	187.6 ± 3.2		541.8 ± 27.8	A B = + 5.1 A C = + 8.4	0.51 0.34
Group *B* Sham-thymectomy rats	19	49.1 ± 0.8	196.8 ± 4.1		515.6 ± 27.3		
Group *C* Normal control rats	20	49.1 ± 0.5	204.5 ± 3.4		499.7 ± 31.7	B C = 3.2	0.71

groups, *A*, *B* and *C*, representing respectively thymectomized rats, sham-operated animals and normal controls. The thymectomies were completed under open-ether anæsthesia according to procedures described by Farris and Griffith[3]. At the conclusion of a 4-week period, 60 animals in each group were selected and equal aliquots tested for histamine resistance. The histamine challenge occurred at four dose-levels, 450, 600, 750 and 900 mgm./kgm. of body-weight. Finney's method of probit analysis was used to calculate the *LD*50 values and dose-response lines[4].

The remaining animals were subjected to drowning stress by immersion in water precooled and maintained at 6° C. Drowning time was determined by recording the time-interval up to the final submergence.

Table 1 presents the *LD*50 results. Comparisons between groups *A* and *B* and between *A* and *C* *LD*50 values indicated that thymectomy induced 6.8 per cent and 8.2 per cent respective increases in the tolerance of the thymectomized rats to histamine stress. Although none of these increases was statistically significant, the low *P* values especially between *A* and *C* approach significance ($P = 0.13$).

Table 1 similarly presents the average time of drowning for the three groups of animals immersed in water maintained at 6° C. Again comparisons between groups *A* and *B* and between *A* and *C* indicate respectively 5.1 per cent and 8.4 per cent increases in the resistance of the thymectomized rats to drowning stress. As indicated by the *P* values, however, none of these increases was statistically significant.

In evaluating the results, it becomes apparent that thymectomy induced similar percentage increases in the resistance of the thymectomized rats to two distinctly diverse types of stress stimuli. The results of this work are thus in accord with previous investigations[2,5]. Although the investigation does not offer conclusive evidence concerning a thymic endocrine function, the results provide support for such a hypothesis.

Plasma Iron and Iron-binding Capacity in the Pregnant Rat and Rabbit

In the latter half of human pregnancy a decrease in blood hæmoglobin concentration usually occurs and this is associated with a decrease in plasma iron concentration and an increase in plasma total iron-binding capacity[1,2]. The mechanism producing these changes is not fully understood. They may be due partly to iron deficiency[3,4], one of the main causes of which is the rapidly increasing fœtal utilization of iron. If so, the changes might be more pronounced in rats and rabbits, in which the combined demands of the fœtuses would be relatively greater.

Blood for the various determinations was taken from 7 rabbits weighing 1.8–2.5 kgm. immediately before and 7, 14, 21 and 28 days after mating and on the first day after parturition. Control values were obtained on blood from a comparable group of 8 non-pregnant animals. In these rabbits no significant changes occurred in any of the values measured

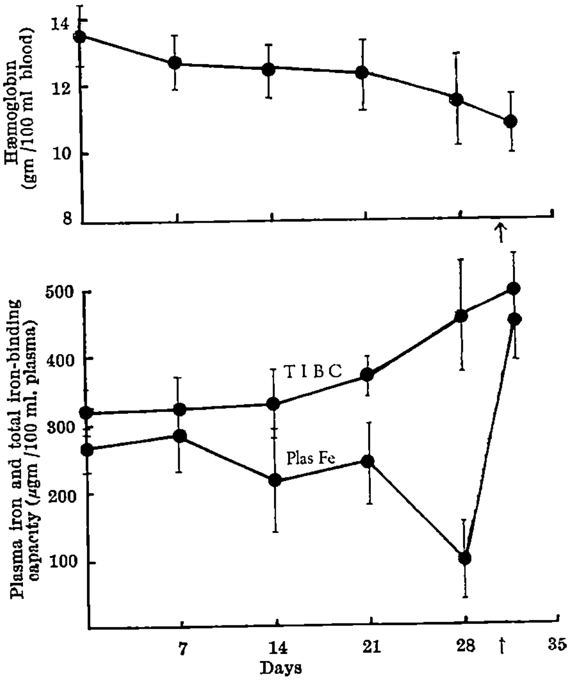

Fig. 1. Changes in blood hæmoglobin concentration, plasma iron concentration (Plas Fe) and total iron-binding capacity (T.I.B.C.) during pregnancy and after parturition in the rabbit. Each point represents the mean of seven rabbits and the vertical lines represent ∓ one standard deviation of the mean. The time of parturition is shown by the arrow.

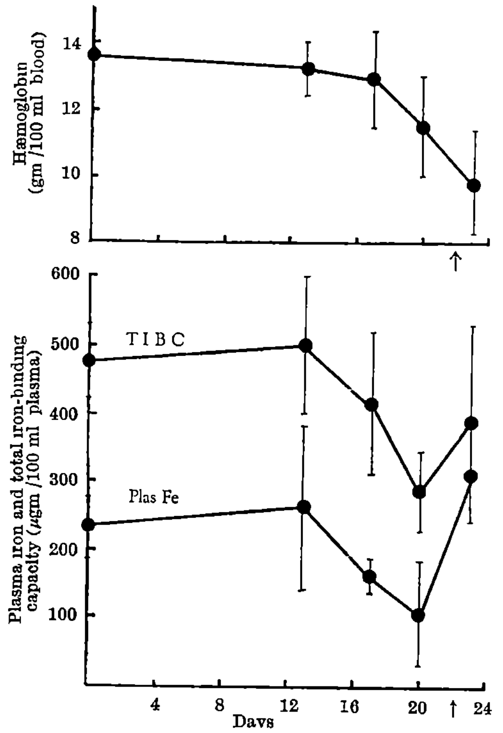

Fig 2 Changes in blood hæmoglobin concentration, plasma iron concentration (Plas Fe) and total iron-binding capacity (T I.B C) during pregnancy and after parturition in the rat Each point represents the mean of six rats and the vertical lines represent ∓ one standard deviation of the mean The time of parturition is shown by the arrow

Twenty-four rats aged 18–22 weeks and weighing 190–220 gm were mated and the day of insemination was determined by daily examination of vaginal smears for spermatozoa The rats were killed in groups of 6 on day 13, 17 and 20 of pregnancy and on the first day after parturition A further comparable group of 6 rats was not mated and determinations were made on these to provide non-pregnant control values The rats were anæsthetized with ether and killed by exsanguination by cardiac puncture

Blood hæmoglobin concentration[5], and plasma iron and total iron-binding capacity[6], were estimated by methods previously described

Both rabbits (Fig 1) and rats (Fig 2) resembled human beings in showing a decrease in blood hæmoglobin and plasma iron towards the end of pregnancy. Both rabbits and rats, however, showed a considerable increase in plasma iron concentration immediately after parturition, while in humans when such a rise occurs it is small[7] In contrast to rabbits and humans, rats showed a considerable decrease in plasma iron-binding capacity in the last few days of pregnancy and a marked rise immediately after parturition

The increase in plasma iron concentration immediately after parturition may be accounted for by the fact that loss of iron to the fœtus is suddenly interrupted Why plasma iron-binding capacity should fall during pregnancy in the rat and rise during pregnancy in man and the rabbit cannot be explained An increase in plasma volume occurs during pregnancy in the rat[8], and this could presumably cause some dilution of the iron-binding protein, transferrin But a similar change in plasma volume also occurs in man[9], where the iron-binding capacity increases during pregnancy[1,2] In the rat, then, it would seem that the decrease of iron-binding capacity could be better explained by alterations in the rates of synthesis and/or destruction of transferrin or by passage of this protein through the placenta or fœtal membranes

Importance of Cell Division for Antibody Production in an *in vitro* System

An *in vitro* system for the study of antibody formation has been previously described[1]. In outline, cell suspensions are prepared from rabbit spleens removed two days after anamnestic stimulation with alum-precipitated human serum albumin The synthesis of antibody *in vitro* is measured by the incorporation of leucine labelled with carbon-14 into antibody protein This system has been used to determine whether cell division or cell differentiation plays a major part in providing the cell population which synthesizes antibody after anamnestic antigenic stimulation

The kinetics of antibody synthesis in earlier experiments and the partial inhibition of antibody formation by a thymidine antagonist, 5-bromodeoxyuridine[2], had suggested that 30–80 per cent of the antibody synthesized was made by cells which divided during the 48-hr. incubation period Autoradiographic studies showed that 2–4 per cent of the incubated cells did indeed take up tritiated thymidine during *in vitro* incubation (to be published), but did not, however, establish that these thymidine-incorporating cells synthesized antibody

The following experiment was designed to provide more definite proof. Tritiated thymidine of very high specific activity was added to the medium The dividing cells incorporated, and hence concentrated, the radioactive thymidine into their deoxyribonucleic acid (DNA), which thus resulted in a very selective irradiation of the dividing cells Under these conditions non-dividing cells would be expected to receive only insignificant irradiation The addition of tritiated thymidine at 1 5 c /m mole at the beginning of the incubation period inhibited antibody formation to approximately the same degree as 5-bromodeoxyuridine Higher specific activities (4 4 c /m mole) did not result in any appreciably greater inhibition Dilution of the specific activity of the tritiated thymidine by the additional presence of unlabelled thymidine reduced or prevented the inhibition (see Fig 1) The inhibition was, therefore, a consequence of an intracellular location of the radioactive thymidine and not simply an unspecific effect of irradiation

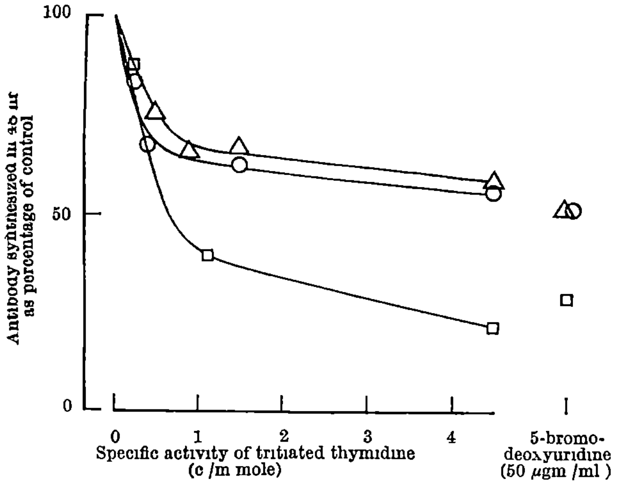

Fig 1 The effect of tritiated thymidine on antibody synthesis The three curves—O, Δ and □—are the results obtained with three separate rabbits The corresponding symbols at the right show the figures for antibody synthesis in the presence of 50 μgm /ml of 5-bromodeoxyuridine for each rabbit

from radioactivity in the extracellular medium A further control was provided by experiments using tritiated water It was found that more than a hundred times as much activity had to be added as tritiated water to produce the same effect as with tritiated thymidine (see Table 1).

That the effect was due to activity concentrated in a most favourable site is supported by a consideration of the calculated doses that the cells received on the basis of various suppositions as to the distribution of the activity (Table 1) By comparison, 200–500 rads of X-irradiation (given at the start of incubation) were required to reduce the antibody synthesis to 50 per cent (to be published) It is not possible to calculate a reliable estimate for the dose received by labelled cell nuclei (see footnote to Table 1) but the figures do provide some basis for comparison.

Table 1 Antibody Synthesis Comparison of Effect of Irradiation from Tritiated Water and Thymidine

	^{3}H water				^{3}H thymidine
Activity in incubation medium, mc /ml	59	5 9	0 59	0 059	0 024
Antibody synthesized in 48 hr as percentage of control	8	37	70	94	42
Dose to cells in rads/hr assuming uniform distribution throughout medium	710	71	7 1	0 71	0 29
Dose to nuclei, rads/hr (see footnote)	(*a*) Assuming synthesis of diploid content of DNA from thymidine at 1 1 c /m mole				*c* 170
	(*b*) Calculated from observed mean grain count over nuclei after autoradiography				*c* 50

In the calculation for the dose-rates to nuclei it has been supposed that the volume of the nucleus was 500 μ^3 and that all the energy was dissipated in this volume In the calculation from grain counts it has been assumed that the overall efficiency of grain development is 5 per cent No allowance has been made for the fact that the activity will not be present in the nucleus until the cell has divided For these and other reasons the figures arrived at can only be taken as a very rough guide to the actual levels of irradiation

Autoradiographs of smears of the cells which had been incubated with thymidine of high specific activity showed very high levels of activity in the nuclei of 2–3 per cent of the cells The rest of the cells showed less than a fiftieth of this activity

Autoradiographs of cells incubated with only tracer-levels (61 mc /m mole) of tritiated thymidine showed proportionately the same grain count per cell. Thus the high specific activity did not appear to affect the uptake of thymidine into the deoxyribonucleic acid (DNA).

There is, therefore, little doubt that the inhibition of antibody formation was due to irradiation from tritiated thymidine incorporated into the DNA of those cells which were dividing

These experiments do not show whether or not a cell can divide after it has started to make antibody In either case it seems likely that most, if not all, of the cells synthesizing antibody have undergone cell division following anamnestic stimulation

These results are thus in agreement with the recent findings of Urso and Makinodan[3] and Baney, Vazquez and Dixon[4], which were obtained by other techniques

PHARMACOLOGY

Effect of Derivatives of L-Cysteine on Growth of *Leuconostoc mesenteroides* (8042)

In the course of work on the chelating properties of certain amino-acid derivatives reaction products of cysteine with eight different aldehydes were prepared The compounds were probably derivatives of thiazolidine-4-carboxylic acid[1–3] They were prepared by previously described methods of synthesis or modifications of such methods[4–6] In Table 1 the compounds are named simply by adding the name of the aldehyde to cysteine

Table 1 Effect of Derivatives of L-Cysteine on Growth of *Leuconostoc mesenteroides* (8042)

μgm cysteine, equivalent per tube	0 1 *N* sodium hydroxide titre (counts) in a potentiometric titrator					
	0	2	4	6	8	10
Cysteine hydrochloride	13	30	50	67	85	95
Cystine	14	34	55	78	99	112
Cysteine-acetaldehyde	13	27	44	65	80	93
,, propylaldehyde	12	32	51	73	88	94
,, butyraldehyde	13	29	49	69	85	102
,, isobutyraldehyde	16	26	44	66	82	105
,, benzaldehyde	13	26	43	54	73	88
,, formaldehyde	11	19	33	47	64	76
,, arabinose	12	19	33	43	59	65
,, glucose	12	21	33	42	53	71

By the courtesy of O R Brækkan, head of the Government Vitamin Laboratory, Bergen, Norway, I was given the opportunity to have the compounds tested as cysteine sources for *Leuconostoc mesenteroides* (8042) by the method described by G D. Shockman *et al* [7] This organism is widely used for the microbiological determination of both cysteine and methionine The results of one test are given in Table 1

It is seen that the compounds fall into two distinct groups The reaction products of cysteine with acet-, propyl-, butyr- and isobutyr-aldehydes were equally well utilized as were cysteine hydrochloride and cystine, while the products formed with formaldehyde, arabinose and glucose were less well utilized

Cysteine-benzaldehyde was intermediate between these groups The results were confirmed for cystine, cysteine hydrochloride, cysteine-formaldehyde, cysteine-butyraldehyde and cysteine-glucose using the same method, and for all the substances listed in Table 1 by a turbidimetric technique In the latter test the concentrations used were doubled as compared with those used in Table 1

These results probably have some bearing on the problem of determining cysteine in the presence of glucose[8–10], and may partly explain why Shockman *et al* [7] get better results in microbiological cysteine (cystine) determinations when they autoclave the glucose separately before adding it to the sterile medium Cysteine-glucose is readily formed in aqueous solutions[6,11] The present results indicate that other aldehydes may probably also influence the determination of cysteine

Second-Generation Toxicity of Malathion in Rats

IN a search for evidence of chronic toxicity of malathion, a breeding experiment was performed with rats under continuous exposure of all old and young animals to this insecticide Malathion is an organophosphorus compound and is regarded as a relatively safe member of the anticholinesterases[1,2] so that it is widely used not only in agriculture but also in home gardening

The experimental animals were Wistar rats bred for many years in this laboratory The control rats received ground Purina Fox chow (Ralston Purina Company of Canada, Ltd , Woodstock, Ontario) The experimental animals were given the same food thoroughly mixed with malathion (technical grade, 95 per cent) purchased from the Niagara Brand Spray Co , Burlington, Ontario In preparing the poisoned diet, 9 ml of malathion were dissolved in 45 ml of corn oil and gradually added in a mechanical mixer to 2 65 kgm of the chow, there was thus 4,000 mgm of malathion/kgm of chow and the daily intake approximated 240 mgm of malathion/kgm of rat

The experiment began with rats aged between 70 and 100 days The colony consisted of 160 rats, equally divided between controls and experimental animals, there were thus 40 males and 40 females receiving malathion These rats have now been fed for 5 months They showed a normal rate of growth and at no time showed any sign of intoxication

Ten weeks after the start of the experiment, eighteen females of the controls and eighteen females of the treated group were selected at random for breeding and were isolated from the main colony, twelve males were also taken from each group The mating cages contained three females and one male, the male stayed in the cage for one week and was then replaced by another male that stayed for the same period of time The outcome of this experiment is shown in tabular form (Table 1) Two of the treated rats had only four young each, a rather unusual number for the breed of this laboratory The average litter sizes and their standard errors tended to be different between the groups, but they were statistically not distinguishable

Table 1 RESULTS OF A BREEDING EXPERIMENT IN RATS TREATED CONTINUOUSLY WITH MALATHION MIXED INTO THE FOOD

	Control	Treated	χ^2	P
No of females mated	18	18		
No of females conceived	13	14		
No of new-born	116	107		
Average litter size ± *S E*	10 5±0 47	8 9±0 68		~ 0 07
No of new-born alive after 7 days	105	56	38 54	< 0 001
No of new-born alive at weaning (21 days)	75	34	22 78	< 0 001

With the purpose of conducting breeding experiments of the second generation, all treated animals that weighed less than 30 gm at the time of weaning were discarded This left 26 of 34 surviving animals which were then matched by 26 control animals of approximately equal weight The average weight of both groups was thus close to 44 gm Nine weeks after birth, the average body-weights of the controls was 152 gm , those of the treated rats 136 gm This evidence for the retardation of growth in the treated group is significant at the 1 per cent level

The general state of health of the rat colony was good, since no deaths have occurred among the adult rats since the start of the experiment However, a number of the young rats in the breeding experiment had ring-tail disease A count at weaning time showed that 18 of 75 (24 per cent) of the control rats but 16 of 34 (47 per cent) of the treated rats had this disease These percentages are different, the statistical significance being at the 5 per cent level

This could mean that the drug has merely sensitized the animals to succumb to infection or other noxious influences In any event, the results are not necessarily a direct consequence of cholinesterase inhibition (1) the pseudocholinesterase activity of the plasma of the chronically treated rats was tested and found to be slightly elevated, this agrees with the finding that an accumulation of cholinesters induces cholinesterase formation in tissue culture[3] (2) Malathion is never chemically pure and the purest preparations tend to be the least dangerous in acute toxicity work[4]

Two recent comprehensive reviews[1,2] make no reference to breeding experiments under exposure to organophosphorus compounds The only comparable work reported in the literature seems to be that by Barnes and Denz[5], who found a high rate of death in the third generation of rats constantly exposed to *E* 605 (parathion) The recent observation of a mutagenic effect of organophosphorus compounds in *Drosophila melanogaster* deserves notice[6] Depression of rate of growth by malathion has been seen in chicks[7] There is also some evidence for the inhibition of growth by antagonists of acetylcholine atropine, procaine, and tetraethylammonium prevent the regeneration of the forelimb in newts[8], and an effect of nicotine might be responsible for the decreased size of the babies of mothers who smoke[9]

Even with the present widespread use of insecticides, most human beings are exposed to not more than traces of these agents, while large doses were used in this work on rats, and even more so in the investigation on *Drosophila* quoted[6] Nevertheless, it would appear that broad investigations of growing cells and insecticides are to be encouraged

5-Hydroxy-3-indoleacetamidine: a New Type of Blocking Agent against 5-Hydroxytryptamine

The possible role of 5-hydroxytryptamine (5-HT) regarding its action on the mammalian nervous system has been discussed repeatedly However, pharmacological investigations were not very successful in clarifying this role The well-known approach of using 'specific' antagonists against the neural effects of 5-HT has been stranded on two grounds (*a*) the commonly known blocking agents of 5-HT are in fact only antagonists of 5-HT on smooth muscles, and (*b*) the actions of 5-HT on nervous receptors, except for a few peripheral sensory and ganglionic receptors, are not adequately explored Recent investigations[1] demonstrate that even those agents which were shown before to block certain hypothetical nervous receptors of the guinea pig ileum[2] are of fairly low potency and/or selectivity to the ganglionic stimulant action of 5-HT The tachyphylaxis observed in the ganglionic action of 5-HT suggested the use of compounds structurally closely related to 5-HT as its possible antagonists One of these compounds, 5-hydroxy-3-indoleacetamidine (5-HTA), which was first described as a 5-HT-like stimulant agent[3], showed the following unique characteristics

(1) In accordance with the data of Woolley and Shaw[3] 5-HTA was found to have pressor action on the nembutalized dog It also stimulated the respiration markedly after intravenous injection of 10–20 μgm /kgm Eighty μgm /kgm intravenously blocked the pressor, reflex-bradycardic and respiratory stimulant actions of 5-HT for a few minutes 5-HT itself, up to 160 μgm /kgm , was unable to influence significantly the actions elicited by 20–40 μgm /kgm 5-HTA

(2) A stimulant action of 5-HTA was found on the pelvic nerve-bladder preparation of the dog, but this action only partly resembled that of 5-HT. Given in doses of 1–4 μgm /kgm intra-arterially 5-HTA evoked a twitch-like rapid contraction. 5-HT in the same dose-range produced a twitch-like reaction at first, followed by a slow contractile second phase[4] The action of 5-HTA and the first phase of the 5-HT action were not inhibited by 0 2 mgm /kgm bromo-lysergic acid diethylamine Morphine, which is known to block nervous receptors sensitive to 5-HT (refs 2, 4, 5), was found to be effective against 5-HT and 5-HTA in doses of 1–2 mgm /kgm No blockage against 5-HT has been observed on the bladder with the small doses of 5-HTA (1–4 μgm / kgm) used

(3) On the isolated rat uterus 5-HTA up to 0 5 μgm /ml did not show stimulatory action, whereas 0 01 μgm /ml 5-HT stimulated the uterus 5-HTA in the concentration mentioned diminished the action of 5-HT only slightly (dose-ratio 4)

(4) Intra-arterial injections of 5–20 μgm. 5-HT and 5-HTA produced contractions of the cat nictitating membrane ('Nembutal' anæsthesia) With temporary occlusion of the external carotid artery, the threshold dose of 5-HT was lowered 2–3 times With this condition the stimulation of the membrane is mainly produced indirectly by stimulating the superior cervical ganglion[5] In contrast, the threshold dose for 5-HTA was rather increased by occlusion, indicating that its stimulant action was chiefly a direct effect on the nictitating membrane 4–20 μgm 5-HTA considerably diminished the ganglionic stimulation produced by 5–10 μgm 5-HT (occluded external carotid artery). The same doses of 5-HTA were less or not effective against the direct stimulatory action of 5-HT on the nictitating membrane (open external carotid artery)

(5) On the inferior mesenteric ganglion preparation of the cat[6] no change or slight increase of the spontaneous post-ganglionic action potentials has been observed by intra-arterial injections of 1–20 μgm 5-HTA The ganglionic stimulant action of 2 5–10 μgm 5-HT, however, was reduced by 1 μgm and inhibited by 5–20 μgm 5-HTA given 30 sec and 4 min before 5-HT The stimulating action of 1,1-dimethyl. 4-phenyl-piperazinium iodide was unaltered by the same doses of 5-HTA

5-HTA is the first compound which shows considerable antagonism against the ganglionic actions of 5-HT Whereas it has stimulant properties on certain organs (urinary bladder, nictitating membrane) it usually lacks stimulant effects on the superior cervical and inferior mesenteric ganglia in the dose-range used So far as its relative potency is concerned, 5-HTA is at least twenty times as potent as either LSD or bromo-LSD, cocaine and morphine against the ganglionic stimulant action of 5-HT It is also more potent than bromo-LSD in preventing the reflex respiratory stimulant action of 5-HT The blocking action of 5-HTA to 5-HT on the rat uterus is weak, inferior to that of LSD, bromo-LSD, chlorpromazine and of many other 'smooth muscle' type 5-HT antagonists The compound seems to have a high degree of selectivity to certain nervous receptors sensitive to 5-HT

HISTOCHEMISTRY

Variation in Lyoglycogen in Starved and Normal Guinea Pigs

It has been shown that the histochemical staining reaction for tissue glycogen depends on the amount of lyoglycogen present in the tissues[1]. The present communication is a preliminary report of the nature of lyoglycogen. Lyoglycogen was obtained from the liver of six guinea pigs, two of which had been starved for 72 hr. and others that had had a normal diet. Hydrolysis of the resultant samples of lyoglycogen was carried out by refluxing with $N/1$ sulphuric acid at 100° C. for 8 hr. The acid solution was neutralized with barium carbonate, filtered and concentrated *in vacuo*. The solutions were applied to Whatman 3 *MM* papers which were developed in *n*-propanol–ethylacetate–water for 15–18 hr. Locating-reagents used were aniline-diphenylamine and silver nitrate.

Glycogen will yield glucose and small quantities of isomaltose on hydrolysis; sometimes other oligosaccharides are present due to acid reversion. The presence of isomaltose in hydrolysates of glycogen is taken to indicate 1–6 linkages in that molecule.

Fig. 1 shows a typical chromatogram. Samples of glycogen from the animals that were well fed yielded glucose and isomaltose in the hydrolysate. Although no quantitative estimates of the amount of isomaltose present in the glycogen hydrolysates from the well-fed animals were made, some indication of the amount of isomaltose present compared with the amount of glucose present may be given by the depth of staining on the chromatogram. The yield of isomaltose from these samples of glycogen seems to be far in excess of the expected quantity or of any that could be produced by acid reversion, consequently the number of 1–6 linkages in the parent glycogen would be greatly increased and may be identifiable with that part of the glycogen molecule or separate polysaccharide that Rosenfeld[2] described as having 33–47 per cent of 1–6 linkages.

The glycogen from the starved animals yielded only glucose. The absence of isomaltose in the hydrolysate obtained from the starved animals suggests a basic difference in the structure of the glycogen molecule in these conditions in that 1–6 linkages are absent.

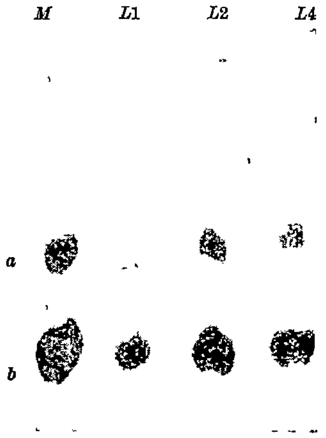

Fig. 1

Fig. 1. *M*, marker; *a*, isomaltose; *b*, glucose; *L1*, glycogen hydrolysate from starved animal (liver glycogen 242 μgm./100 mgm. liver wet weight). *L2*, *L4*, glycogen hydrolysate from fully fed animals (*L2*, liver glycogen 1,130 μgm.; *L4*, liver glycogen 1,012 μgm./100 mgm. liver wet weight). Note absence of isomaltose in *L1* and excessive amounts of isomaltose in *L2* and *L4*

From this preliminary work on glycogen that can be detected histochemically, it seems that the nutritional state of the animal has some influence on the structure of the glycogen molecule.

We thank Dr. W. J. Wheelan for his valuable suggestions and his gift of the disaccharide isomaltose.

HÆMATOLOGY

Specific Antigens of Human Leucocytes and Thrombocytes

Attempts have been made to classify the specific antigens of human white blood cells and platelets, by using immune sera prepared in rabbits[1,2], sera from pregnant multiparous women[3,4] or from patients receiving multiple transfusions[5,6]. The different methods used by the various authors led often to inconsistent results.

In the present work immune sera from rabbits, monkeys and multiparous pregnant women have been used and compared using different serological methods.

Results obtained with rabbit anti-human leucocyte and thrombocyte sera showed the presence of common antigenic constituents of human erythrocytes, leucocytes and thrombocytes. These species specific antibodies of low titre (1/20–1/80) could easily be removed through appropriate absorptions. Common antigenic properties of thrombocytes and leucocytes of various species could also be observed. These antibodies, which were cell-specific for man, rabbit, mouse, sheep, guinea pig and rat, could be absorbed easily.

The titres obtained in rabbits against human leucocytes and thrombocytes were 1/640–1/1,280. The anti-leucocyte sera prepared against the leucocytes of a single donor reacted with leucocyte samples from every other human donor although with varying intensity, which may be due to differences in the agglutinability of the cells, with no correlation to their antigenic structure. The absorption of the serum with cells of any donor abolished completely the titre against all other donors. Similar results were obtained with thrombocytes.

The immune rabbit sera reacted strongly using the direct agglutination, agar-gel precipitation and tanned cell hæmagglutination tests. No correlation has been found between the intensity of agglutination of the leucocytes and the thrombocytes of the same donor.

The reactions obtained with the monkey anti-human leucocyte and anti-thrombocyte sera were similar to those obtained with the rabbit sera using the direct agglutination technique. The monkey antisera gave weaker reactions with the agar precipitation and the tanned cell hæmagglutination techniques.

The results obtained with sera of multiparous pregnant women differed significantly from those obtained with the animal anti-sera. Only direct agglutination could be used Agar-gel diffusion was negative and tanned-cell hæmagglutination weakly positive Sera of five hundred women during the second half of their pregnancy were examined All women had been pregnant between five and fifteen times Fifty sera (10 per cent) were found to contain leuco-agglutinins in a titre of at least 1/10 Two sera were found to contain thrombo-agglutinins of a similar titre These positive sera were examined each against leucocyte and thrombocyte samples obtained from thirty-six different blood donors[7] Only compatible blood donors were used, most of them being of group *O*

Table 1 summarizes the results obtained with fourteen different leucocyte samples when examined against ten different human anti-leucocyte sera It can be seen that some of the sera as well as some of the cell samples show antigenic similarity This similarity was especially well pronounced when whole families were investigated

PATHOLOGY

Cultivation of Monolayer Cultures of Frog Renal Cells

CONSIDERABLE evidence has been accumulated by Lucké[1], Duryee[2], Rose[3], Tweedell[4], and others for an agent which induces an organ-specific adenocarcinoma in the kidney of the leopard frog, *Rana pipiens* Lucké[1] has postulated that this agent is probably of a viral nature Although a percentage of the animals develop palpable renal tumours after a long and variable period of time following injection of tumour material, it is still desirable to devise other methods to propagate and possibly isolate the infective agent At the same time, the large dimensions of the frog cells make them an ideal system with which to study the initiation of any subcellular modifications following incubation of cells with the tumour-inducing agent

A procedure has been developed to provide an adequate *in vitro* host system Adult frog kidneys, normally relatively sparse, slow-growing tissues in culture[5], are treated with trypsin by a method modified from that of Youngner[6] and Bodian[7], both using mammalian cells The resulting cell suspension produces extensive cell sheets

The animals, after being pithed, are perfused with calcium-free amphibian Ringer's solution (sodium chloride, 0 66 gm , potassium chloride, 0 015 gm , dextrose, 0 02 gm , phenol red, 1 00 mgm , penicillin, about 500 units per ml , double glass-distilled water, 100 ml. and sufficient 0 15 *M* sodium bicarbonate to make a final *p*H of 7 6) through the still-beating hearts of the animals to rid the kidneys of a majority of the trapped red blood cells by the resulting dilution of the blood The organs are then dissected, minced, and washed twice in calcium-free amphibian Ringer's solution at room temperature To ensure proper digestion of the kidneys, the organs are kept for 24 hr , or overnight, at 2°–4° C in a fresh 0 25 per cent trypsin (Difco 1 250) solution in calcium-free Ringer s solution (*p*H 7 8) after 1 hr exposure to the trypsin solution at room temperature before cooling
